"The motion picture is one of the very effective ways of impressing American standards, material, equipment and methods on the Chinese," says the report received, "and films would be welcomed, showing construction and completion of American roads. A good film showing the entire process of the manufacture of automobiles and vividly picturing the advantages to the purchasing public of quantity production could be advantageously exhibited."

Owing to the fact that the bill did not pass, the Department of Commerce is asking manufacturers to supply it with films which will be at once forwarded to China and other countries. A translator and film expert are located at the department, who will adapt films for the particular countries to which they are sent.

Advantages to Great Britain and Canada

In discussing this subject with the Congressional Committee, the Department of Commerce pointed out that other nations, and particularly Great Britain and Canada, have found the motion picture an excellent means of promoting trade. Canada expended $40,000 for this work during February. As far back as 1913 Great Britain exhibited moving pictures of leading British industries in Europe, Canada, United States and South America.

Many, and in fact most, of the moving picture films exhibited throughout the world showing the United States are of the "Wild West" character, and instead of giving a fair representation of existing conditions they distort foreign impression. To counteract, and at the same time develop American foreign commerce, the department is urging this motion picture propaganda.

How Germany Sells Her War Vehicles

Organization of Manufacturers to Help Stabilize Motor Industry

WASHINGTON, March 17—In Germany, according to a consular report, twenty automobile manufacturers organized in 1915 for the purpose of taking over motor vehicles released by the army, and disposing of them so as to create the least disturbance to the automobile industry. The organization was known as the Feldkraftwagen Aktien-Gesellschaft, or Feldag.

It was generally expected that the automobile market would be flooded after the war, but according to an article in the Frankfurter *Zeitung* for Dec. 20, 1918, of which this is a summary, there is not the slightest danger of any immediate flooding of the market, in view of the great scarcity of repair parts. Even in the case of passenger vehicles, the present supply, especially of the lighter models, is far below the demand, and sales are now restricted to customers who need the vehicles for the performance of their professional duties, like physicians and veterinarians.

Some of the passenger vehicles of foreign makes were disposed of to neutral countries during the war, on account of the difficulty of securing duplicate parts. The Feldag is endeavoring to sell the vehicles only after having put them in good running order. But as under the present labor conditions repairs require much more time than under normal conditions, and in view of the scarcity of storage facilities, it was found necessary to sell limited numbers of unrepaired vehicles.

Private Orders Annulled

The apprehended drop in prices has also failed to materialize, especially in the case of commercial vehicles. A 3-ton truck which sold for about 16,500 marks ($3927) before the war and which may now be obtained for not less than 30,000 marks ($7200), with tires of iron and wood, is now sold by the Feldag, after a thorough overhauling, for 12,000 ($2880) to 14,000 ($3360) marks.

The fact that army contracts for about 10,000 trucks are still outstanding has also a steadying effect on the market.

Under the circumstances it is not surprising that private firms find it difficult to purchase trucks at reasonable prices. It is recalled that a few months ago the association of automobile manufacturers decided to annul all private orders for vehicles received prior to Dec. 31, 1916, on account of the abnormal increase in wages and materials. While orders are now accepted again by the manufacturers, the scarcity of raw materials and the general uncertain conditions make it necessary for them to stipulate a delivery period of several years and to protect themselves thoroughly in regard to prices.

Prior to the war it is estimated Germany had probably about 7000 to 8000 trucks in use. At the outbreak of the war most of them were taken over by the army, and during the war only about 2000 to 3000 vehicles assigned to the home forces were available, partly for public and partly for private use. An increase through return of army trucks is not to be expected, in view of the fact that their number was much smaller than it was generally anticipated, and also because of the armistice provision for the surrender of 5000 trucks to the Entente.

—

Mexico Breaks Oil Pact

WASHINGTON, March 12—President Carranza has demanded immediate payment of "royalty taxes" on oil produced in Mexico in January and February despite his agreement with the United States to take no further action in Mexican oil matters until the Mexican congress could act on a new oil law.

—

France May Import Tractors

WASHINGTON, March 15—The French Government will allow the importation of farm tractors from the United States provided commercial credits for one year can be arranged. Details of the plans are not yet known. The only advice received so far is a cablegram from Bernard M. Baruch stating: "The French Government is willing to allow sales to French merchants of $40,000,000 worth of machine tools and all agricultural implements if commercial credits for one year can be arranged."

—

Copper Producers to Market Government Surplus

WASHINGTON, March 18 — Copper producers have arranged with the War Department to market the government surplus copper at the prevailing market prices, charging the government the actual cost of so doing. It will be distributed with the producers in connection with their own products, the minimum monthly amount being fixed, and the actual amount disposed of being a certain percentage of total sales exceeding the minimum amount. It was also agreed that the copper be entirely distributed within 15 months.

—

Permanent Exhibit of War Materials

WASHINGTON, March 17—The Engineering and Standardization Branch of the Purchase, Storage and Traffic Division of the Army will establish and maintain an exhibit of standard war equipment and supplies. The exhibit will contain samples of all varieties of standard articles necessary for war, and is especially intended for the information of manufacturers, and in order to have available at all times approved samples or specifications of samples needed to facilitate production. A list of the articles which will be placed in this permanent exhibit will be made public later.

Improve Wood for Aircraft

New Methods for Seasoning and Testing Developed by Forest Laboratory

WASHINGTON, March 18—The use of plywood in aircraft construction and the development of improved kiln-drying are reported as a result of experiments by the Forest Products Laboratory, Department of Agriculture. One of the most important achievements was the discovery of a method to dry spruce in 30 days as compared with the two years heretofore required.

At the time our aircraft program was launched practically no seasoned spruce stock was available. To air-dry green spruce 3 in. thick, such as is used in airplanes, requires from one to two years. The Forest Products Laboratory specified a method of kiln-drying by which green spruce airplane stock can be dried in from 20 to 40 days to the proper moisture content. Kilns were designed for the Army and Navy and for commercial companies capable of properly drying airplane stock, and men were furnished to operate them until operators could be trained at the laboratory. Seasoned stock was thus insured equal, if not superior, to air-seasoned material.

A relatively slight advantage in lightness and strength over the best substitute makes spruce the preferred airplane wood and warranted the organization of a Spruce Production Division. The same importance attaches to any saving in strength, however slight, that is accomplished through proper methods of seasoning. Exhaustive tests are showing that the Forest Service specifications produce better material than can be secured by drying in the air.

Strength of Airplane Woods

Over 300,000 tests made on about 130 species of wood afforded basic information for aircraft design. From these data the relative suitability of various species of wood, the influence of defects, the relation between strength and density, and the influence of moisture can be determined. A table of strength values at 15 per cent moisture was prepared by the forest products laboratory, and adopted by the Army and Navy as a basis for the design of the wooden parts of aircraft.

Tests of Beams and Struts

On account of the difficulty in securing suitable pieces for manufacturing the larger airplane parts and the necessity for conserving material, several series of tests were conducted at the laboratory on built-up beams and struts of various designs and also on various types of splices. Present specifications of the Army and Navy for laminated and spliced beams and laminated struts are based on the results of these tests.

Automotive Conditions in England

War Has Opened Question of Air and Road Transportation and Government Control

LONDON, March 1—Pending a definite ending of the war, certain regulations of the Defense of the Realm Acts (commonly styled D. O. R. A.) continue to be operative. Under these powers the competent authorities have placed a temporary embargo on certain arranged for and other tentative and more or less experimental efforts to commercialize services by aircraft.

The Position of Aircraft Manufacture

One of the problems of the hour concerns the future of aircraft manufacture. For some time to come no stable commercial output of aircraft seems possible, if only for lack of data and experience of the sort of machines required. Aircraft for the naval and military forces and for postal work has a recognized place, and forms part of the Government's program for land and sea defense.

There is a rumor that certain aircraft factories will remain more or less under control of the state; though possibly not wholly excluding private trading. This rumor finds some strength in the better established report that certain accessories factories are now a state monopoly. One of these is concerned with ball bearings and has supplied all its war time output to the Government. If the rumor be correct, it will be helpful to the legitimate and orderly setting up of aircraft manufacture on a commercial basis, and it was largely because of the absence of this powerful help before the war that much of the languishing state of practical aeronautics in this country was due. The British government virtually has created and indirectly influenced the capital of this new industry, and it is fitting for it to continue its aid, just as years ago the torpedo and high-speed water craft were developed principally at national cost.

Reference to ball bearings prompts the remark that American interests are being increasingly felt here, and it looks as though the German pre-war monopoly here in these bearings is likely to be transferred, though not to the same extent, to the United States. Two or three makes are well known here, the tractors being the machines which seem to have drawn most attention to them. At present there seems to be a dearth of British makes of ball and roller bearings and an over-production of British magnetos.

Need National Highway System

One of the biggest, probably the largest development, concerned with the British motor industry, centers in the reorganizing of a national road system of motor transport. The railways, it is stated, will be nationalized, and virtually they are so already, in common with the canals or internal waterways, most of which the railway interests acquired years ago and have done nothing to develop or even continue the use of. Already the upkeep of the roads has become a national charge though the control was not unified.

Matters are shaping to a complete control by the state, both as regards the better use of the roads, for reducing congestion of railway traffic, and in respect of their cost of upkeep. Moreover it is known that there is a big scope of development of road traffic in perishable produce. Hitherto something like $95,000,000 was spent yearly on British roads by some 2500 local authorities, and now it is estimated that $500,000,000 is required to fit them to carry motor traffic of the sort intended.

Big Field for Road Development

A big field of development is promised which may be summed up as—

Extension of tractor farming and fruit and vegetable culture.

Increased speed of road traffic, especially for perishable stuff.

Development of rural and urban passenger traffic.

Encouragement for soldiers and others to settle on the land.

Encouragement of short and medium distance motor goods traffic of the heavier sort, this provision carrying with it the corresponding one of assured return journeys with adequate remunerative loads.

On this score it may be said that during the second half of the war period, government controlled efforts were made through the local chamber of commerce in some of the chief goods centers to develop motor road traffic for distances up to 100 miles. It has been stated by one traffic expert that railway transit is cheapest for distances exceeding 50 to 100 miles, and motor transit cheaper for distances under those limits, but this view may be modified where a better organization for return loads has been established on a sound basis. At the moment there is some important opposition to the government's scheme regarding the ministry of transport. there being a fear lest the railway interests may predominate in the working of the system.

Schemes for light railway lines corresponding to the roadside railways of Belgium are being discussed as supplementary means, and there is also the bigger prospect of a national electrification scheme to supply current at from one to two cents per unit from giant power stations erected near the coal pits and metallurgical gas furnaces. If a national system of motor road transport with roads adequate to the loads were available, direct use for 50,000 motor trucks could be found for the rural development hoped for.

There is and has been much criticism of the government's action in not declaring its intentions regarding the disposal of war trucks and in building a central truck repair depot near London. This depot has exceeded the provisional estimate of $5,000,000 by $3,750,000 and if completed doubtless will cost still more. It had its origin in two circumstances—the increasing number of idle vehicles "held up" for lack of repairing facilities, while the factories from which they came were daily adding to the number of new ones, and the issue accentuated by the mishap on the Western Front in March and the fears of a possible further "set back"; the effect being to reduce the available repair bases and depots.

The truck industry offered to deal with these vehicles at about 1/7 of the cost of the government scheme, under certain conditions, intended to recoup them for the outlay required. The virtual cessation of hostilities, of course, may, or may not, affect the utility of this scheme, but there can be little doubt that its necessity, if ever warranted on the grounds of urgency and economy, is now much reduced.

Both the manufacturers' and the public's points of view must be considered in this matter. The government has some 50,000 to 60,000 trucks in a generally repairable and usable condition. The manufacturers urge that they should have these vehicles of their own make returned to them to be repaired for re-sale to the public. One suggestion on this score was for the manufacturer to buy them back from the government, and another was for them to repair them at the national cost and be reimbursed at a scheduled rate.

From the public standpoint it is urged that these vehicles are national property and should not be accorded different treatment than is traditional with other army and public service stores listed for disposal.

Rigid Airships for Commercial Use

There has been published an official memorandum by the Air Ministry which sets out the merits of the airship against those of the airplane, regarded from the commercial standpoint. It is lengthy and its conclusions are in favor of the airship of the rigid type, on the following, among other, grounds:

Greater capacity and radius of useful flight of the airship for long distances and time in the air.

Greater capacity (the latest rigid German airship carrying over 38 tons gross, and has a cruising speed of 45 miles an hour, for 177½ hours, or seven days, and a gross distance capacity for 8000 miles in that period, with a maximum attainable speed of 77.6 miles an hour.

Relatively lower cost of the airship from the superior capacity denoted under the foregoing heads.

The objection that the airship is a fair-weather machine is replied to by the observation that during 1918 there were only nine days on which no airship flight could be made in the British Isles, which are recognized as one of the worst weather areas in the world.

Am-pe-co in New Plant

MARSHALLTOWN, IA., March 19—The American Machine Products Co. has moved into its 3-story plant and has changed its trade-mark from Ampeco to Am-pe-co so that the pronunciation cannot be mistaken.

A. & B. Mfg. Co. To Make Hurlburt Trucks

NEW YORK CITY, March 17—The affairs of the Hurlburt Motor Truck Co., which went into the hands of creditors last month, seem to be working out satisfactorily through an agreement submitted to the creditors in open court on March 14, whereby the American & British Mfg. Co., Providence, will be licensed to manufacture 1,000 Hurlburt trucks in consideration of which it will pay the receiver of the Hurlburt company approximately $176,000 in cash as the trucks are sold. The A. & B. company will also purchase the Hurlburt parts on hand which are roughly estimated to be worth $150,000. The 1000 trucks will be sold by the Hurlburt Sales Co., a new corporation to be formed for the purpose.

The creditor's committee, consisting of H. G. Banta, Edward C. Striffler, Inc.; M. L. Bayard, Keystone-Hindley Gear Co.; and E. H. Brodwell, Fisk Rubber Co.; has reported that the business operations of the Hurlburt company from January 22 to March 4 produced a revenue of $124,716 at an expense of $110,796.29, leaving a profit of $13,919.71 to which should be added profit on work in process of $9,811.60, and profit on the service department of $5,292.18, making a total profit for the period of $29,023.49. The committee has been unable to estimate the liabilities to date but indicates that they will be between $850,000 and $1,000,000. All claims must be sent to the creditor's committee at once for consideration.

Wire Wheel Brings Suit for Patent Infringement

NEW YORK, March 15—Suit has been brought by the Wire Wheel Corp. of America against the Budd Wheel Corp. The plaintiff claims infringement of the Pugh patent, No. 1,030,428, for the process of indenting and perforating the rims; of the Duffy patent, No. 1,125,498, for an automatic locking hub construction; of the Pugh patent, No. 903,608, for a protected lock, and of the House patent, No. 1,166,130, for a radially swinging lock.

The Wire Wheel Corp. of America has granted licenses to the Standard Roller Bearing Co., Philadelphia, which employs only the Pugh patent, No. 1,030,428; to the Hayes Wheel Co., Jackson, Mich., and the Dayton Wire Wheel Co., Dayton, which uses all four patents. The suit has been opened in the Eastern District of Virginia.

Old Chandler Officers Re-elected

CLEVELAND, March 17—The officers of the Chandler Motor Car Co. were reelected at the company's annual meeting as follows: President, F. C. Chandler; first vice-president, C. A. Emise; second vice-president, W. S. M. Mead; third vice-president, J. R. Hall; secretary, Isadore Grossman; treasurer, J. M. Regar. The only change in the company's directorate was the election of J. R. Hall, factory manager, to succeed J. V. Whitbeck, whose work as chief engineer interfered with his service as director. Mr. Whitbeck remains as chief engineer. Other directors, besides the officers, are: John Sherwin, Charles A. Otis and James A. Fayne.

Premier Motor Corp. Appoints Executive Committee

INDIANAPOLIS, March 18—A committee of three has been formed to take over the active management of the Premier Motor Corp. This committee is just another name for the manufacturing committee which has been in control of several phases of the company's activities for some time, and is composed of the same members, C. S. Crawford, F. T. Nehrbas and E. F. Schaeffer. The manufacturing committee has been changed to the executive committee, so that it can take over some of the duties of the company's president, A. C. Flowers, who is unable at this time to devote all of his attention to Premier affairs.

Buick Expansion

FLINT, March 17—The Buick Motor Car Co. has orders for every machine it can produce up to July 1. The company is now producing over 400 cars daily, and notwithstanding the set-back caused by war reconstruction hopes to equal its 1917 production of 135,000 cars. More men are now employed than when the armistice was signed.

A warehouse and loading dock have been completed, which can accommodate 1000 cars. By a double decking arrangement an additional 1000 machines can be stored. A new bronze and aluminum foundry is just being finished and will be in operation soon. The present foundry building, which adjoins the sheet metal plant, will be used for the further expansion of sheet metal work. A three-story building, designed and built for the manufacture of Liberty motors, has been completed, but inasmuch as peace has brought aircraft engine work to a halt, the new structure will house the tool designing department.

Automobile & Supply, Ltd., New Canadian Incorporation

TORONTO, March 15—W. S. Smith and associates took over stock, trade, assets and good-will of the Automobile & Supply Co., Ltd. The new firm is being incorporated with the name of the old company shortened to Automobile & Supply, Ltd., and continues at the present premises. Automobile & Supply, Ltd., are distributers for Pierce-Arrow, Paige, Hupmobile and Gray-Dort passenger cars and Federal and Pierce-Arrow trucks.

Tube Co. Buys $300,000 Site

DETROIT, March 18—The Detroit Seamless Steel Tube Co. has purchased a $300,000 site for its proposed $2,000,000 plant to be built within the next year. It is at West Warren and Wyoming Avenues and contains 60 acres.

Detroit Tractor Corp. Making $750 Tractor

DETROIT, March 18—The Detroit Culto-Tractor Corp., a newly organized concern, capitalized for $1,500,000, is about to place a $750 tractor on the market. The first machine has been completed and production will start on the first thousand about April 1. The company has completed arrangements for a manufacturing plant. H. M. Jerome, formerly chief engineer of the Allis-Chalmers Mfg. Co., is production manager as well as vice-president. S. R. DuBrie is chief engineer and secretary. Joseph A. Rowe is president, and E. H. Kramer treasurer.

Specifications of Tractor

The new tractor is a one-wheel drive machine. It is balanced by a side-wheel. The motor is V-type, 4 x 6, low compression, equipped with Bosch magneto, impulse starter, Stromberg carbureter, Pearce governor and air-washer. The gear ratio is 30 to 1, having a working speed of 2½ miles per hour with a drawbar pull of 1200 lb.

The water in the radiating tank is below the cylinders, so as soon as the motor stops all the water drains back into the tank. This eliminates all chance of the operator forgetting to drain the motor and prevents the cylinders from freezing. The arch straddling the rows has a clearance of 46 in. so corn that high may be passed over without injuring it. The total weight of the machine is 1800 lb. The company proposes to establish assembly plants in Seattle, Minneapolis, Kansas City and Dallas, and states that orders for 2500 machines are on hand.

Standard Parts Now in Own Building

CLEVELAND, March 18—On the first of the month the Standard Parts Co. moved its central offices, which include the executive and supervisory staff, bookkeeping, advertising and contracting departments, to the Standard Parts Building on Walnut Avenue at East Eleventh Street, which has just been completed.

National Wire Wheel Enlarges Plant

GENEVA, N. Y., March 17—The National Wire Wheel Works, Inc., maker of Pasco Wire Wheels, has arranged for additional factory equipment at Hagerstown, Maryland. With this and the present factory the company will be prepared by June 1 to manufacture 3000 wheels per day, and will arrange the equipment to still further increase this production as required. During the past year the concern has been practically entirely devoted to government production on airplane wheels and airplane parts. Direct factory selling branches have been opened in New York, Chicago, San Francisco, Kansas City, Dallas, Seattle and Minneapolis, as well as nine of the largest cities in Canada. Service stations have been equipped also in the larger cities.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

A. O. Smith Building Rumors

MILWAUKEE, WIS., March 17—That the A. O. Smith Corp. is preparing to double the size and capacity of its plant at 27th Street and Keefe Avenue is the basis of well-defined rumors current here. Color has been lent to the reports by applications made in the last few days to the public land commission of Milwaukee seeking the vacation of certain streets adjacent to the present Smith works. At the general offices of the company it was stated that no statement was available at this time. Reports concerning the project are to the effect that construction work will begin as soon as technical matters on street vacation are adjusted. It is said that the additions will be ready for occupancy by Sept 1, at which time the Smith working force will be increased to 4,500 or 5,000 operatives.

Madison to Make Trucks and Tractors

ANDERSON, IND., March 15—The Madison Motors & Tractor Corp., capitalized at $1,200,000, has been formed for the purpose of making tractors and trucks. This company is an outgrowth of the merger last fall of the Bull Tractor Co., Minneapolis, and the Madison Motors Corp., Anderson, formed for the purpose of making tractors and trucks for the United States Government during the period of the war. With the cessation of hostilities, however, the financial interests back of the companies determined to incorporate, and have added $500,000 of new capital, bringing assets and cash up to a sum in excess of $1,750,000. The company will build 1500 Bull tractors and 1000 Madison engines during the present year. C. E. Gibson is president, the directors including the president and L. N. Rosenbaum, manager; A. H. Ebert, C. H. Jockmus, eastern bankers, and J. F. Green, formerly president of the Bull Tractor Co.

U. S. Tractor Co. to Build Plant

MENASHA, WIS., March 17—The reorganization of the United States Tractor Co., Chicago, as a Wisconsin corporation, styled the United States Tractor & Machinery Co., preparatory to the transfer of the works and general offices to this city, has been completed. The new company has a capital stock of $250,000 and the following Menasha men are incorporators: Joseph G. Sailor, George G. Barlow and Dr. A. B. Jensen. The first unit of the new plant will be erected at once. It will be a 1-story fireproof building, 60 x 150 ft.

Nash Production Reaches 100 Mark

KENOSHA, WIS., March 15—The Nash Motors Corp. has completed its contract, which called for 1600 Quad trucks for the Government, and is winding up its war work. It is now devoting 90 per cent of its attention to its regular car production. In February 65 cars were produced daily. In March production will be increased to 90 cars, while the 100 mark will be reached early in April.

New Dodge Four-Door Sedan

NEW YORK, March 17—Dodge Brothers dealers are expecting deliveries within the next two weeks of a new four-door sedan which will sell for $100 more than the present two-door model, making the price of the new model $1,876. The chassis will be the same as at present.

Baker R. & L. Co. to Make Custom Bodies

CLEVELAND, March 17—The Baker R. & L. Co., makers of the Rauch & Lang electrics and the Owen magnetic car, has entered the custom body field. Several years ago this company established a special body department, but until recently has confined its efforts to special designs for manufacturers and dealers, individual custom work not being solicited. Now, however, facilities have been expanded, and the company is producing original designs to meet the wishes of individual owners.

Airplane Factory Will Close

MARBLEHEAD, MASS., March 17—The Burgess Co. airplane manufacturer, which employed 2000 people at its plant, will be closed Saturday. It turned out many of the training planes used by the government during the war.

Flechter Opens Los Angeles Branch

NEW YORK, March 15—L. V. Flechter & Co. has opened a branch in Los Angeles. It is in charge of M. J. Siebert, who for ten years has been road salesman for the Neptune Meter Co., a subsidiary of the Flechter company. J. J. Frank has been appointed district manager of sales for the Metropolitan district.

Frost Gear Adds

JACKSON, MICH. March 15—The Frost Gear & Forge Co., at the annual stockholders' meeting, increased its capital stock from $350,000 to $750,000, and approved plans for an addition, to be of steel construction, 75 x 150, with concrete basement, south of its present plant. The heat treating department will be located in the new building. All old officers and directors were re-elected.

Gillette Rubber Takes Eau Claire Mfg. Co.

EAU CLAIRE, WIS., March 15—The Gillette Rubber Co. has taken over the plant and business of the Eau Claire Mfg. Co. for manufacturing machinery and equipment for the tire trade.

General Motors Drive on Trucks

LANSING, MICH., March 18—W. C. Durant, head of the General Motors Corp., has disclosed the general plan for the expansion of that company's property in Michigan. It provides for improvement in the Olds Motor Works as well as the embodying of the Reliance Engineering Co. plant into the General Motors unit in this city. The nature of the product it will turn out has not been revealed.

A substantial part of the General Motors appropriation for 1919 will be spent here. The general plan calls for additions to present factory buildings to care for proposed increased production, and a great increase in the working force.

The General Motors Corp. will go in extensively for trucks this season, a manufacturing adjunct not heretofore attempted in the Olds Motor Works plant.

Making Ford Truck Bodies

OXFORD, MICH., March 18—Henry Houck & Son have organized here for the manufacture of truck bodies for Ford cars.

Elgin Distributing Co. Opens

NEW YORK, March 17—The Elgin Motor Distributing Co. has been formed to take over the Metropolitan distribution of the Elgin. It is located at Broadway and Fifty-seventh Street. The company consists of: President, M. W. Sanger; vice-president, E. L. Sanger; secretary, Henry Weiss; treasurer, Harry Sanger, and assistant secretary, David Sanger.

Velie Production Calls for 15,000

MOLINE, ILL., March 18—The Velie Motors Corp. is back from war to peace work, and is turning out on an average of 45 machines daily. The company aims to manufacture 15,000 cars this year.

Produce Six Roamers Daily

KALAMAZOO, March 15—The Barley Motor Car Co. is at present producing at the rate of 6 cars a day and plans to increase this production at once. Recently the company's buildings have been completely rearranged with this increase in production in mind.

Napoleon on 1 and 1½-Ton Trucks

TRAVERSE CITY, MICH., March 17—Active production of 1 and 1½-ton trucks has been started by the Napoleon Motors Co. The original plans of the company were to turn out about 864 Model 9 1-ton trucks and 136 Model 11 1½-tonners for 1919. The company, however, has now planned a larger production, ranging from eight to ten trucks daily, and, in order to facilitate this increase, has asked the Michigan Securities Commission for permission to sell the remaining $350,000 worth of the unsubscribed common stock. The 1-ton model sells for $1,285 and the 1½-tonner at $1,485. Both models have

overhead valve 35 hp. four-cylinder engines, 3½ by 5 in. With the exception of a difference in gear ratios, tire sizes and weight, the two models are alike. Other features include thermo-syphon cooling, Hotchkiss drive, Stromberg carbureter, Connecticut ignition and single unit Auto-Lite starter.

Republic Sales Amount to $15,749,628

NEW YORK, March 17—Gross sales of $15,749,628 are reported in the financial statement of the Republic Rubber Corp. for the year ended Dec. 31. The net amount carried over as surplus for the year is $602,913.

The balance sheet for 1918 and 1917 is as follows:

Assets

Land, buildings, equipment, etc.	$4,606,973	$5,323,540
Investments in other companies	375,836	128,370
Inventories	6,843,245	5,159,268
Cash	493,885	483,759
Accounts and notes receivable	2,043,036	2,445,582
Due from officers and employees	126,817	29,797
Deferred stock subscriptions	512,780	......
Stock contract with officers	......	100,000
Unadjusted balance of proprietary selling companies	......	232,618
Patents	2	1,054,601
Unpaid stock subscriptions	1,500,000	......
Liberty bonds	61,070	......
Miscellaneous investments	8,198	......
Deferred items	146,645	402,287
Expenses applicable to future operations	109,425	......
Total	$16,827,915	$15,359,822

Liabilities

Common stock	$1,634,010	$4,164,453
Preferred stock	8,867,400	6,755,400
Notes and accounts payable	6,088,718	3,291,715
Salaries and wages payable	......	115,355

Dividends Declared

Willys-Overland Co., Toledo, regular quarterly dividend on preferred, $1.75 per share, payable April 1 to stockholders of record March 20.

Firestone Tire & Rubber Co., Akron, quarterly on common, $1.50 per share, payable March 20 to stockholders of record March 10.

The Stutz Motor Car Co. of America, Inc., declared its regular quarterly dividend of $1.25, payable April 1 to stockholders of record March 22.

The Michigan Drop Forge Co., Pontiac, has declared a monthly dividend for March of 15 cents a share on common stock, payable April 1, to common stockholders of record March 15.

Keystone Tire & Rubber Co., Erie, Pa., declared a stock dividend of 15 per cent, payable May 20 to stockholders of record May 1; also the regular quarterly dividend of 3 per cent on the common stock, payable April 1 to stockholders of record March 21.

Aviation School in Peru

WASHINGTON, March 18—A military aviation school will be established in Peru, according to a recent decree by the president of the country.

Studebaker Earns $3,884,195

Production Curtailed by Government Orders — New Plans Discussed

SOUTH BEND, March 17—The Studebaker Corp. of America shows net profits of $3,884,194 for the year ended Dec. 31, after all deductions were made, as compared with $3,500,741 in 1917.

The balance sheet of the Studebaker Corp., as of Dec. 31, 1918, compares as follows:

ASSETS

	1918	1917	1916

A. R. Erskine, president of the corporation, in his remarks to stockholders, explains the cutting down of production due to war orders, and the proposed enlargement of the company's plant. In 1918 the company produced 18,270 cars and 58,830 horse-drawn vehicles, of which about 50 per cent were delivered on war contracts. When the contract was given on May 18 for 155 millimeter shells at the rate of 4000 per day, $4,250,000 was provided for increased plant facilities. Complete war contracts called for:

Government	Ordered	Invoiced
United States	$30,792,221	$17,140,341
Sundry U. S. contractors	187,195	187,195
Total U. S.	$30,979,416	$17,327,536
British	18,946,135	14 962,385
French	1,351,250	1,351,250
Russian	3,801,551	3,801,551
Total	$55,078,353	$37,442,723

Of these government contracts, $8,200,000 is still due from the United States and Great Britain. From the standpoint of profits it is said that war contracts only netted 4.8 per cent. on sales.

Of the increased plant facilities undertaken to take care of war orders, one-half of a new machine shop was completed when the armistice was signed, two-thirds of a forge shop and the 8000-hp. power house. When finally completed the plant will have an annual capacity of 100,000 cars. In order to complete the new plant as soon as possible, the directors authorized the sale of $15,000,000 of 7 per cent ten-year serial gold notes, to provide funds for the floating debt of the company and to finance the plant extensions planned for this year. About one-third of the plant will be finished this year and by February, 1920, it will be producing 3000 cars a month.

The Detroit plants will continue in production of the more expensive cars and this city will take over the small model. The production schedule for 1919 calls for 40,000 cars. Plant No. 1, Detroit, heretofore used for car production, will be given over to manufacture, storage and shipping of parts. Plant No. 2, leased, used for parts storage only, will be given up. Plant No. 3, Detroit, will be used for car manufacture exclusively this year with castings, bodies, springs and some forgings supplied by the plant here. In the first quarter of this year 6500 cars will be produced and 4000 per month thereafter. Neither the company nor its dealers has a stock of cars on hand. By the end of December all war contracts were cancelled and the company is now back in steady commercial production.

Lee Rubber & Tire Profits $200,348

NEW YORK, March 17—Net sales of the Lee Rubber & Tire Corp. were $4,609,924, or $536,029 ahead of 1917, according to the financial statement of the company for the year ended Dec. 31, 1918. Net profits, after all the necessary deductions were made, amounted to $200,348, or $177,759 more than $22,589 made last year.

The balance sheet for the last three years compares as follows:

Assets

	1918	1917	1916
Cash	$379,977	$155,960	$258,560

Dividend Besides Profit Sharing

TOLEDO, March 18—Following an announcement recently of a $400,000 dividend on preferred stock, payable April 1, Clarence A. Earl, first vice-president of the Willys-Overland Co., stated that this dividend has no reference to the company's recently inaugurated 50-50 profit-sharing policy.

He explains that the dividend represents a return on invested capital, and that the profits to be divided with employees are those in excess of such dividends, and also legitimate compensation for labor. The dividend is the regular quarterly payment and is to be $1.75 on all preferred stock of record March 20. The Willys-Overland Co., as already stated, proposes to distribute to its employees one-half of all its profits over and above a fair return on invested capital.

Hayes Sales Increased $230,820 Over 1917

DETROIT, March 18—The Hayes Manufacturing Co. has placed on sale $800,000 cumulative preferred stock, bearing 8 per cent interest. Dividends are payable quarterly on the first days of February, May, August, and November.

Sales for 1918 increased $230,820 over 1917. Last year's sales totaled $3,753,381 as compared with $3,512,460 for 1917. During the last of 1918 about 40 per cent of production was war business, all of which has now been closed. These contracts are now being settled. Completed orders now on the company books total $1,250,000 for delivery before May 15.

The balance sheet, as of Dec. 31, 1918, is as follows:

Assets

	Dec. 31, 1918	Aug. 31, 1917	Mar. 31, 1916

Hart-Parr Report Shows $113,402 Net Loss

CHARLES CITY, IA., March 17—The annual report of the Hart-Parr Co. for the year 1918 shows net loss of $113,402. Comparison with previous reports is difficult because of a change in fiscal year, but the accomplishments of the company during the year were surprisingly favorable and are not all reflected in the balance sheet. Current liabilities were but 58.8 per cent of current assets, as compared to 79.7 per cent in the previous year. There was a charge off of $993,037 for bills receivable, obsolete inventories and other possible losses. Real estate was charged off to the amount of $577,649. The company has claims of $120,000 against the Government for work done during the year.

—

Nash Reclassifies Capital

KENOSHA, WIS., March 17—In accordance with action taken by stockholders earlier in the year to enable employees to participate in the ownership of the company, the Nash Motors Co. has amended its corporate articles to the effect of reclassifying certain shares. The total capitalization is not increased by the change. The authorized capital includes 198,000 shares of preferred, par value $100, and 52,000 shares of common, without par value, or a total of 250,000 shares.

20 Per Cent Increase in Hood Rubber Sales

BOSTON, March 19—Net sales of $22,341,081 are reported in the annual statement of Hood Rubber Co. for 1918. Compared with $18,573,765 in 1917, it is an increase of 20.2 per cent, and with $11,666,501 in 1916 is an increase of 91.5 per cent and 145.9 per cent over $9,083,693 in 1915. Of the 1918 sales about $5,000,000 were tires and $17,000,000 rubber footwear. Dividends of 12 per cent were paid on the $3,000,000 common stock in addition to 7 per cent on the $4,000,000 preferred, leaving $354,000 to be added to the surplus after deduction of taxes and depreciation. On Dec. 31 last the company had a working capital of $5,380,000, the largest in its history, and an increase of 64 per cent over 1916.

Following is its comparative balance sheet:

Manly Resigns from Curtiss

BUFFALO, March 18—Charles M. Manly, who has been vice-president of the Curtiss Aeroplane & Motor Corp., has resigned and will return to New York, where he will devote his attention to the development of the Manly Hydraulic Transmission System for motor trucks and will also open general engineering offices. Mr. Manly is president of the Society of Automotive Engineers.

J. O. Hofbauer, formerly general sales manager of the Paige-Detroit Co., New York, has joined the Lexington Motor Co., New York, in a similar capacity. A. J. Wise will succeed him at the Paige-Detroit Co.

Brigadier General B. P. Disque, who has had charge of spruce production for airplanes on the Pacific Coast, has been honorably discharged from the army.

Captain V. K. McBride, Ordnance Department, who was at Jackson during the war and transferred to Detroit after the armistice, has been made assistant to E. W. Hurd, sales manager of the Premier Motor Corp., Indianapolis.

Frank Shaw, traffic manager of the Harroun Motors Corp., has resigned. Previous to joining the Harroun Co. he was connected with the Studebaker and Maxwell companies.

Major H. W. Alden has received his discharge from the army and has returned to Detroit. He is vice-president of the Timken-Detroit Axle Co. and will be active as consulting engineer.

H. L. Frost has been appointed production manager of the Parrett Tractor Co., Chicago Heights, Ill. He was formerly connected with the Ford Motor Co.

J. W. Flannery will be Eastern representative of the Corcoran Mfg. Co., Cincinnati.

Robert E. Page, for four and a half years assistant foreign sales manager for Dodge Brothers, has joined the Commerce Motor Car Co., Detroit, to act as a district sales manager in Canada.

Claude Greenhoe has been appointed chief engineer of the motor bearings division of the Hyatt Roller Bearing Co., Detroit, to succeed R. G. Wells, who has been promoted to chief engineer of the Hyatt factories at Newark, N. J. Mr. Greenhoe comes to the Hyatt company from the Militor Corp. Prior to that he was connected with the Republic Motor Truck Co., the King Motor Car Co. and the American Gear & Mfg. Co.

H. A. Goddard, former representative in Michigan for the Standard Parts Co., has resigned to take charge of the sales and advertising of the Militor Motors Corp., Jersey City, N. J.

Men of the Industry

Changes in Personnel and Position

Pomeroy Leaves Vauxhall Motors for America

NEW YORK, March 18—Laurence H. Pomeroy, technical director of the Vauxhall Motors, Lt., Luton, England, and engineer of the Vauxhall automobiles, is expected to arrive in America in a few days. Mr. Pomeroy has practically severed connections with the Vauxhall company, but retains the right to manufacture his design of car in the United States. His latest innovation is a valve-in-the-head 4-cylinder design known as the 30-98 Vauxhall, which has quite extraordinary performance records.

Mr. Pomeroy's paper on the value of valve-in-the-head engine design appeared in AUTOMOTIVE INDUSTRIES in two installments in the issues of Feb. 20 and 27. It was presented before the British Institution of Engineers.

J. H. Malone, advertising director of the Chilton publications, Philadelphia, has resigned to become vice-president and general manager of the William F. Hudson enterprises, Philadelphia, which include the Hudson Motor Specialties Co., Hudson Motor Axle Co., Precision & Thread Grinder Mfg. Co., and the Hudson Peck Machine Products Co.

S. A. Host has resigned as director of publicity of the Lincoln Highway Assn. to become connected with the Lincoln Motor Co., Detroit, under Frank G. Eastman, advertising manager.

Conroy Fiero, Washington, D. C. representative for the Buda Co., Harvey, Ill., has recently gone to Europe and will visit England, France, Belgium, Italy and, if possible, Russia, to investigate conditions for marketing Buda engines.

J. J. Callahan is in charge of the eastern branch office of the Moltrup Steel Products Co., Beaver Falls, Pa., which has recently been opened in the Woolworth Building, New York.

J. E. Duffield has been elected vice-president in charge of sales of the Essenkay Products Co., Chicago, and will assume his new duties immediately. Until recently he was general manager and treasurer of the Bailey Non-Stall Differential Corp.

M. H. Blank has been appointed chief engineer of the Lynite Laboratories of the Aluminum Castings Co., Cleveland. He was recently honorably discharged as captain in the army. Previous to entering military service he was assistant engineer of the Premier Motor Corp.

Wills Out of Ford

DETROIT, March 17—C. Harold Wills, one of the designers of the Ford automobile and a member of Henry Ford's organization for 18 years, has severed his connection with that company and will engage in business for himself. He was chief engineer of the Ford Co. and became associated with Mr. Ford two years before the present company was organized. He expects to open temporary offices here. The nature of his new business is not announced, but it is understood he will remain in the automotive field.

Danish Firm to Represent American Industries

NEW YORK, March 15—Paul Fridericksen, representing Bendix Bros., Copenhagen, Denmark, is in America arranging for certain lines of motor cars, tractors, trucks and accessory representation. Bendix Bros. is a large firm which has handled farm machinery in Denmark, and has distribution through 300 or more dealers. Mr. Fridericksen is looking for two lines of motor cars and several accessories, such as tires, ignition apparatus, etc.

Frank W. Hammond, formerly with the Bates Tractor Co. and for a number of years connected with the sales department of the Lansing Wagon Co., has been placed in charge of the passenger cars agencies in eastern territory by the Reo Motor Car Co., with headquarters in Lansing.

John O. Munn, assistant advertising manager of the Willys-Overland Co., Toledo, has become advertising manager and assistant sales manager of the Republic Motor Truck Co., Alma, Mich.

E. S. Leonard, Detroit, connected with the Garford Motor Truck Co., Lima, O., has been appointed sales manager of the White motor truck division of the Simons Sales Co., Detroit.

Fred C. Warner, president of the Oakland Motor Car Co., Pontiac, has been elected president of the Chamber of Commerce of that city.

Ralph C. Chestnutt, formerly with the Willys-Overland Co., is now assistant chief engineer for the North American Motors Co., Pottstown, Pa.

E. W. Snyder, for many years with J. B. Sipe & Co., is now with the Hilo Varnish Corp., Brooklyn. He will make his headquarters in Pittsburgh and represent the company in western Pennsylvania, eastern Ohio and northern West Virginia.

$2000 for Heinze Tractor

BOYNE CITY, MICH., March 17—The retail price of $2000 has been fixed on the Heinze four-wheel drive tractor by its manufacturer, the Traction Engine Co. of this city.

*Sept. 1—Uniontown, Pa. Speedway race.
*Sept. 20—Sheepshead Bay, L. I. Speedway race.
*Oct. 1—Cincinnati, O. Speedway race.

†Sanctioned.
*Tentative dates.

CONVENTIONS

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.
April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

Foreign Trade Opportunities

WASHINGTON, March 15—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received requests for automobile or parts agencies of business from individuals and companies in foreign countries. These are listed below. For further information address the Bureau of Foreign and Domestic Commerce and specify the Foreign Trade Opportunity number.

A man in France desires an agency for the sale of motor cars. Correspondence may be in English. References have been supplied. No. 28670.

A firm in Norway wishes to purchase automobiles and supplies, and rubber goods. Payment, banker's confirmed credit in New York. Correspondence may be in English. References supplied. No. 28680.

A man in Algeria desires an agency for the sale of medium grade automobiles selling for about $1700. Correspondence may be in English. No. 28682.

A man in Mexico desires the sole agency for the sale of automobiles and supplies. References have been filed. Foreign Trade Opportunity No. 28364.

A man in France desires an agency for the sale of farm tractors. Correspondence should be in French. No. 28366.

An agency is desired by a man in Venezuela for the sale of automobiles. References have been filed. No. 28367.

A man in France desires an agency for the sale of motor cars and accessories. Correspondence should be in French. References have been filed. No. 28372.

A company in Australia wishes to secure an agency for the sale of all motor accessories and supplies. References have been filed. No. 28375.

An agency is desired by a man in France for the sale of farm tractors. Correspondence may be in English. References have been filed. No. 28384.

A man in France desires an agency for the sale of farm tractors. Correspondence may be in English. References have been filed. No. 28386.

An agency is desired by a man in Algeria for the sale of automobiles and farm tractors. Correspondence may be in French or Spanish. References have been filed. Foreign Trade Opportunity No. 28473.

A business man in France desires to purchase separate parts for engines and motor cars; and motor car and truck chassis. Correspondence may be in English. References have been filed. No. 28476.

A man in Spain desires to secure a general agency for the sale of farm tractors of from 10 to 12, 14 to 16 and 18 to 20 hp., operated by petroleum, gasoline and wood fuel. Quotations should be given f.o.b. New York. Correspondence should be in Spanish. No. 28477.

A man in Belgium wishes an agency for the sale of automobiles, trucks and farm tractors. Correspondence should be in French. No. 28485.

To Dispose of Surplus Acids

WASHINGTON, March 15—Surplus stocks of acids owned by the War Department are to be disposed of in co-operation with the acid committee and in such a way as not to affect the market. Approximate quantities held by the Government are as follows: Sulphuric acid, 4400 tons; oleum, 300 tons; nitric acid 1000 tons; mixed acid, 2600 tons; spent acid, 700 tons.

CAUTION

This tag is attached to all genuine Stewart Repair Parts.

LOOK FOR IT!

If you don't find this tag, you are getting imitation substitute parts. Refuse to accept them.

The use of imitation parts on any Stewart Product, at our option, invalidates the Stewart guarantee.

For your own protection demand genuine Stewart Parts.

STEWART-WARNER SPEEDOMETER CORPORATION

"Handle Only Genuine Stewart Parts and It Will Be Very Profitable"

—Miss Stewart Custombilt

"The only kind of repair parts for Stewart Products that will give genuine Stewart Service are **genuine** Stewart Parts.

"Due to the fact that over 4,000,000 Stewart Products are in use, it is natural that the parts business has become quite large. So much so, in fact, that several outside firms have been tempted to offer inferior imitations of Stewart Parts.

"Now, I know that consciously you would not consider for one moment giving any one of your customers a counterfeit, that can never be as good as the original. You value their trade too highly, for your success depends upon its continuance.

"However, that's exactly what you do when you sell them any part for a Stewart Product that is not made by the Stewart-Warner Speedometer Corporation, that does not bear the name Stewart and has not attached to it one of our red tags.

"When a customer comes in, needing some part for a Stewart Speedometer, Vacuum System, or any other Stewart Product, it's natural that he expects to get a genuine Stewart Part. If you offer him anything else an explanation is necessary, time is lost for you and there is a mighty big chance of your **customer** being lost for you.

"Now, I am personally interested in every single one of my 4,000,000 Stewart users. I am going to make it my business to see that they get only genuine Stewart Parts. So in all of my big Saturday Evening Post ads this year, I am going to use perfectly good and valuable space to tell them to demand the genuine, with the red tag attached.

"Here's a real tip—if you handle only the genuine, you can make a mighty valuable business out of the sale of Stewart Parts."

Yours for the genuine always,

Miss Stewart Custombilt

(Posed by Miss Marilynn Miller)

VOL. XL — NEW YORK—THURSDAY, MARCH 27, 1919—CHICAGO — NO. 13

New Models at Lyons Fair

Citroen, Fiat and Delage Have Post-War Types Ready—Fiat Four-Cylinder 2.5 by 4.3 Gives 34 M.P.H.—Citroen Four, 2.5 by 3.9 Four-Cylinder, for $1470

Electric Equipment, Detachable Cylinder Heads, Unit Engine and Gearbox Are Features—Both Production Models

By W. F. Bradley

LYONS, FRANCE, March 10—Some idea of the several post-war models to be shown at the Lyons Fair has been obtained by a recent visit to French and Italian factories, and while the majority of the French and Italian makers have not post-war models ready, the work of Fiat and Citroen is indicative of what may be expected. The new Fiat, with 105 in. wheelbase, has a touring equipment weight of 1800 lb. The four-cylinder engine is designed to give 23 hp. at 2800 r.p.m.

Andre Citroen has created nothing short of a sensation in Paris manufacturing circles by his determination to produce 100 cars per day. He is one of the first to have produced a car with left-hand control and the gearbox controls mounted in the center.

The size of the small Fiat and of the Citroen is very nearly the same. Both use a four-cylinder engine of the L-head block type. The Fiat has cylinders 2.5 by 4.3 and Citroen cylinders are 2.5 by 3.9. The Fiat uses a 50-in. thread.

Editor's Note—W. F. Bradley, European correspondent for AUTOMOTIVE INDUSTRIES, *has in the last three months visited most of the French automobile factories. Previous to the opening of the Lyons Trade Fair he obtained engineering details and photographs of the new Fiat, the new Citroen and the post-war Delage. Mr. Bradley's cable message from Lyons on the opening of the fair appeared in* AUTOMOTIVE INDUSTRIES *March 6, page* 509.

Fuel consumption has been looked after in both of these models. The Citroen has a fuel consumption of 31 miles to the American gallon, traveling at 40 m.p.h.

Four Fiat Models

Four models are comprised in the Fiat post-war program. These cars, which are all new design, comprise a light four, a medium four, a good-quality six, and an ultra-select six. The first model to be offered to the public is the light-weight four, officially known as Model 501, which was uncovered at the trade fair here.

It is evident that Fiat has profited much by war experience, for, while continuing to remain in the high-class field, changes in design have been made in order to simplify construction, to reduce upkeep and to get weight down as low as possible.

Weighs 1800 Pounds

Model 501 is a four-seater with a four-cylinder engine, 65 by 110 mm. (2.5 by 4.3 in.) bore and stroke, the reduced track of 50 in., wheelbase of 105 in., and total weight with full touring equipment of 1800 lb. The car is offered complete with electric lighting and starting, detachable steel spoke wheels of 700 by 90 mm., speedometer drive off gearbox, tools, and all accessories.

A speed of 44 miles per hour is claimed for this car with full touring equipment. This is not exaggerated,

tests showing that the average car can beat this figure. The engine revolves up to 2800 r.p.m., at which speed the power developed is 23. The power curve, however, shows that at 1400 r.p.m. the engine develops more than 15 hp., and that the maximum torque is obtained at 1000 r.p.m. With a final gear ratio of 1:4.8, the car is an excellent performer at moderate engine speeds and has a very lively pick-up. Standard bodies are built in the Fiat shops, but provision is made for custom bodies when desired.

The engine is a unit construction with clutch and gearbox, this unit being secured by three-point suspension: to the side frame members and to the forward transverse frame member. Cylinders are L-head type, moderately offset, with waterjacket extending to the base of the casting, and are mounted on an aluminum base chamber divided horizontally. The lower portion of the base chamber acts as an oil reservoir. The second housing bolted to the engine contains the clutch, the gearset and the universal.

Detachable cylinder heads make their appearance for the first time on a Fiat. Experiments, however, extend back nearly 3 years, and it was only after exhaustive comparative tests that the engineers decided the balance of advantages lay with the detachable rather than with the fixed head.

The forward transverse shaft driving magneto at one end and water pump at the other is an old Fiat feature which has been maintained.

The adoption of chain drive for the camshaft and the electric generator is new, however. There is a single chain for these three shafts, adjustment being made by rotation of the electric generator, the shaft of which is set eccentrically.

Three-Bearing Crankshaft

Although such a small and compact engine, the crankshaft, which has a diameter of 1.4 in., is carried in three plain bearings. Connecting rods are I-section, machined all over, and pistons are cast iron, with three compression rings and a bevelled oil return groove. The skirts of the pistons are drilled considerably. The wrist pin is hollow and is locked in the connecting rod, the piston being equipped with bronze bushes.

Lubrication is under pressure through a hollow crankshaft to the main bearings, the connecting rod bearings and to the camshaft bearings. Formerly the oil pump was on the end of the camshaft; now it is in the base of the engine, but driven off the camshaft. In addition to a fine gauze filter the whole length of the base chamber, there is a filter around the pump. There is a dashboard pressure indicator, as well as a float in the center of the base chamber, with dial on the side of the engine.

Electric Equipment Mounting

An interesting feature of the engine is the neat manner in which the electric generator and the starting motor are mounted. Both of these are of cylindrical section mounted in cylindrical extensions of the crankcase casting. The generator is on the upper portion of the engine base chamber, just below the water pump. The bolt which passes through the split portion of the housing serves not only to hold the generator in position, but also acts as chain adjuster. The thread on this bolt meshes with a worm cut on the circumference of the generator, and serves to rotate the latter, thus tightening or slackening the driving chain, as the case may be. When the correct tension has been obtained, the whole is locked in position by a nut on the bolt.

The electric starting motor is carried in a similar manner on the lower portion of the engine base chamber.

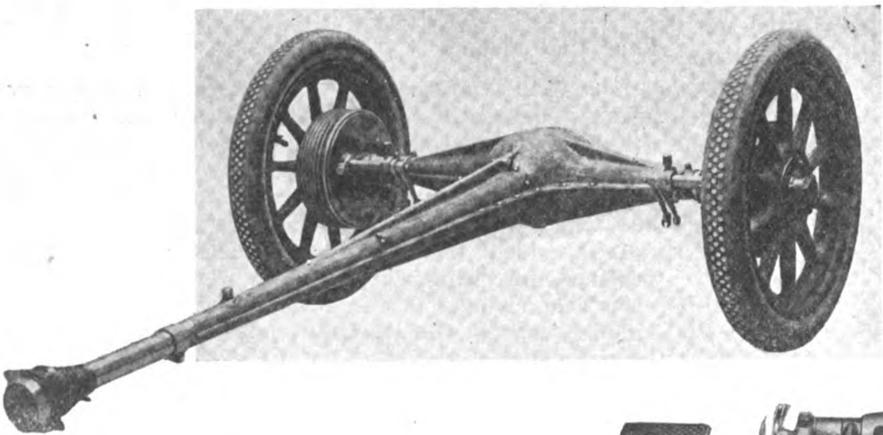
Unit Powerplant Design

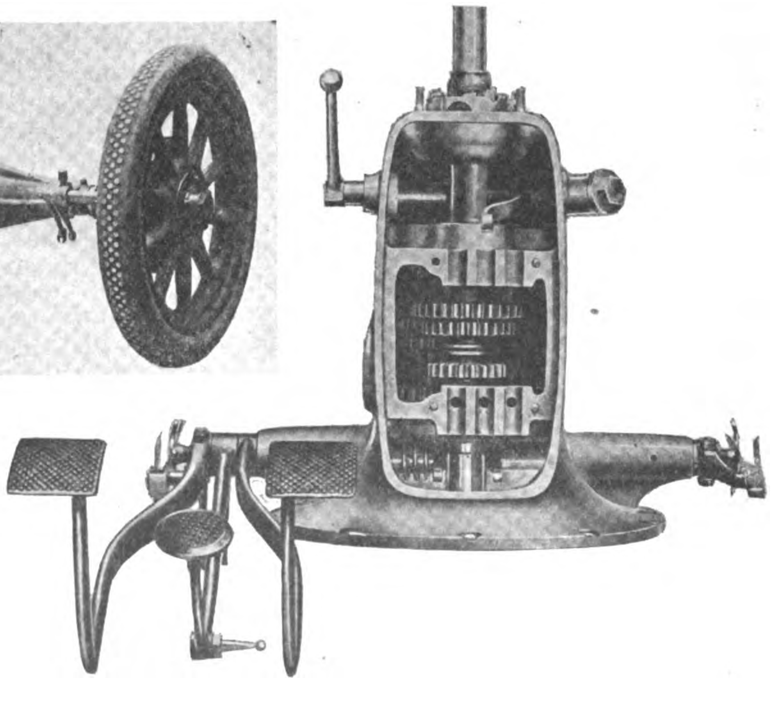
The second portion of the unit is an aluminum casting which contains the clutch, the gears and the universal, and has all the pedals mounted on it. An interesting feature of this housing is that it is divided into three distinct compartments. The forward compartment, which is 13 in. overall length, contains the clutch and the clutch withdrawal mechanism.

In the center is the gearbox proper, which is 6 in. long and $5\frac{1}{2}$ in. wide.

The rear compartment receives the universal joint and the selector lever for the change speed mechanism. A lid, held down by two nuts, uncovers the entire box. But inside this there is a second lid over the gearbox only, this lid holding in position the three selector rods. On the side of this casting there is a filler by means of which oil is fed to the universal.

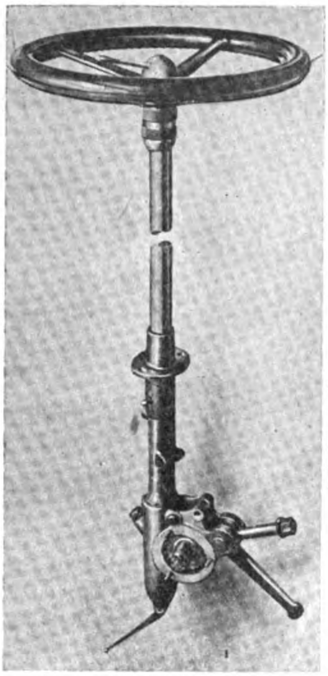
For a number of years the Fiat rear axle design has



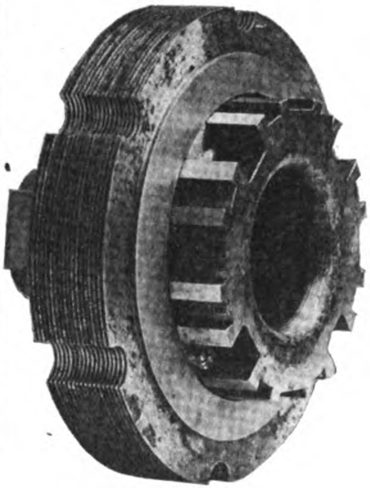


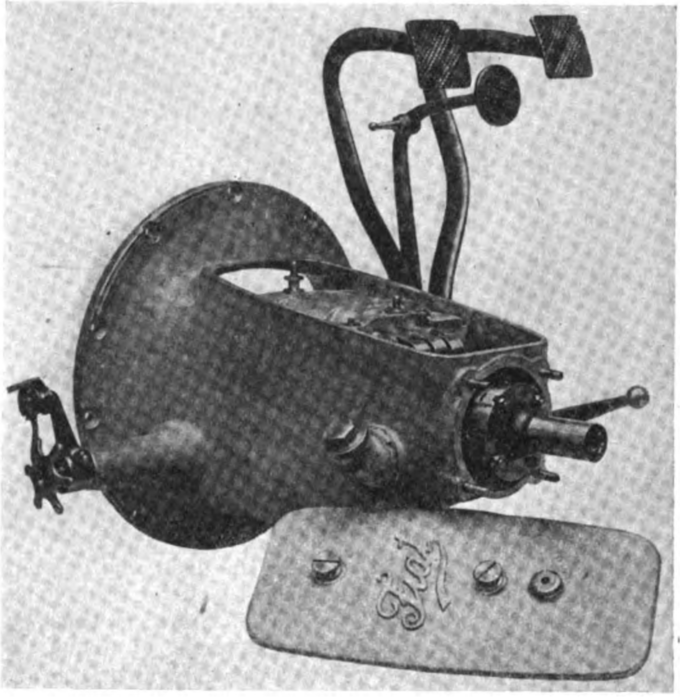
Above—Simple but rugged construction of the rear axle housing and brakes of the new Fiat

Right—Gearset and universal joint housings on the new Fiat, showing also the method of attachment of the clutch, brake and accelerator pedals. Note filler on the gearbox



Left — Fiat steering column with carbureter controlled by an outer revolving sleeve
Lower—Type of disk clutch used on the new Fiat
Right—Combined gearset, clutch and housing





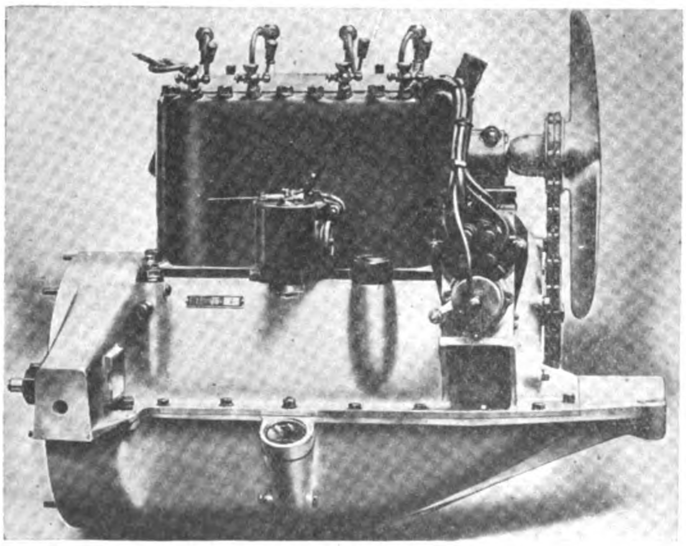
been a couple of steel stampings bolted together in a horizontal plane. These two stampings are retained, but instead of being bolted they are welded together, and a big cover plate is fitted on the rear of the differential housing. This type of axle is very light and possesses considerable strength. Formerly it had the disadvantage of calling for considerable labor in dismounting. Now it is only necessary to disconnect the universal and pull the differential shafts out of engagement in order to withdraw the entire differential, crown wheel and pinion and propeller shaft. The differential shafts carry the load as well as transmit the drive. As the propeller shaft is of considerable length, there is a white metal bearing at the center of its length, merely to steady it and prevent whip when taking up the drive.

Brakes are side by side on ribbed rear wheel drums, the diameter of the drums being 11½ in. and the width 3.1 in. Brake liners are cast iron on aluminum.

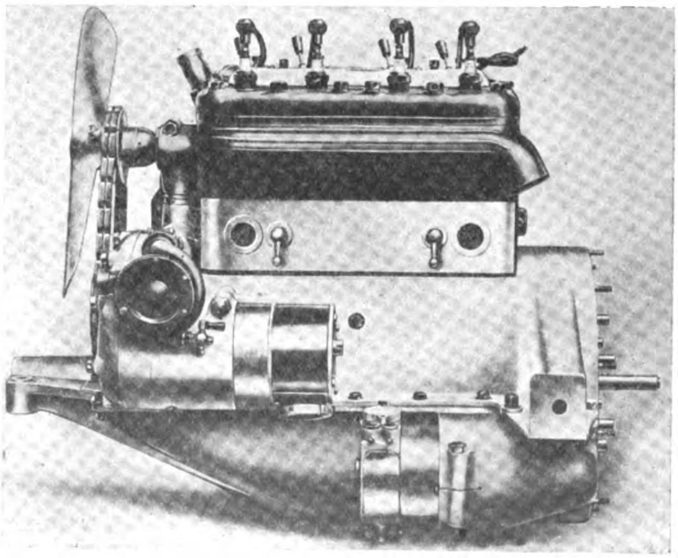
Final drive is by means of spiral bevel cut on Gleason machines. Fiat has been making use of this for about 3 years on all staff cars supplied to the Allied armies, and has decided on its adoption for all touring models.

Changes have been made in the attachment of the propeller shaft housing. Formerly this terminated in a heavy fork, which was connected up to a heavy cross-frame member. The end of this housing now terminates in a sphere, which is bolted up to the end of the gearbox. The drive and the torque are taken through this organ, the springs, which are underslung semi-elliptics, having no other duties than to take care of the suspension of the car. Rear springs are 2 in. in width and are fitted with a reversed leaf above the main leaf, this acting as a damper to prevent rebound.

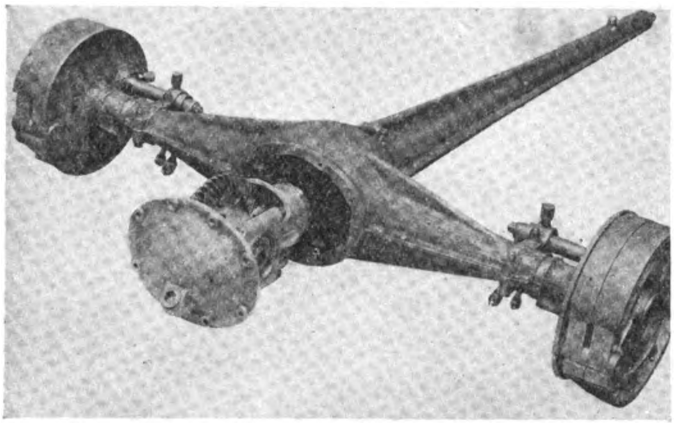
Steering is worm-and-wheel type, and not worm and sector, and is mounted on the forward face of the right-hand crankcase hanger. A ball thrust bearing is fitted on the steering column. Ignition is controlled by a lever on the top of the steering column, and minimum carbureter setting is carried out by turning the sleeve on the steering column.

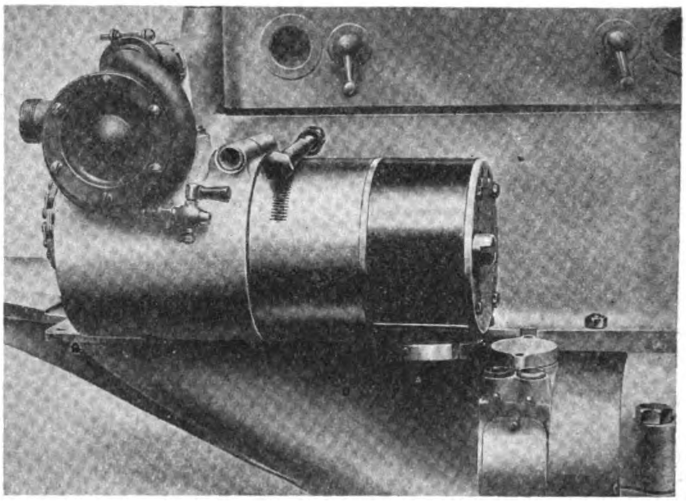


Carbureter side of new Fiat engine. Cylinder head is detachable



Exhaust side, showing neat arrangement of starting-lighting equipment





Above—New rear axle construction of the Fiat light car, showing Gleason gears
Right—Fiat generator, showing method of adjustment

The gas tank is carried through the dash, one portion of this tank being on the engine side and the other portion on the body side of the dash. Flow is thus by gravity. There is a reserve compartment of about 1.5 gal. inside the main tank, and this can be drawn from by a three-way cock on the engine side of the dash.

Care in Equipment

All the electrical equipment of this car is built in the Fiat shops. Although this model is a popular type and ought to be a big seller in all European countries, there has been no skimping on details. As an instance, all the electric wires are carried in metal conduits, all joints are lapped; in every case provision has been made to prevent all oil leakage either by means of washers or more commonly by oil return spirals; the wearing surfaces in the steering gear can be renewed by turning the wheel; the front wheels are carried in an inner double ball bearing and an outer spherical and thrust bearing, while careful provision has been made by means of a special guard to prevent dust entering or oil leaking; provision is made for driving the speedometer from the gearset; wheels are steel, hollow spoke type, with a spare carried in a bracket on the side of the body.

In addition to this light-weight car, other Fiat models to be produced at an early date are a full-sized touring model with four cylinder engine of 75 by 130 mm. (2.9 by 5.1 in.), a high-class six with the same bore and stroke, and a super-de-luxe six of about 85 hp., details of which have not yet been issued.

Citroen Four-Cylinder Car

DURING the war the biggest shell-producing factory in France was the establishment owned by André Citroen, in Paris, where 50,000 projectiles were turned out every 24 hours. Before the armistice, Citroen had decided that his post-war activities should comprise the construction of automobiles, bicycles and sewing machines. Within 3 months of the signing of the armistice he had his new car ready, and within 5 months of the cessation of hostilities he will be producing at the rate of 100 complete cars per day.

On an average the automobile factories of France, which have not entirely been taken off the work of building cars, will not have their new models out before the month of June or July. Citroen, who never did build a complete car before this year, claims that he will be in full production before the end of April. His figure of

100 per day astounds the trade, for no other firm in France, or in Europe, has risen to such an output. Citroen's methods of marketing and advertising are so aggressively American that they have aroused quite a lot of controversy. Admirers see in them wonderful business and organizing ability and critics profess to look askance at a car which needs so much booming. In the meantime Citroen is showing his advance models everywhere, is establishing service depots throughout France, and is continuing to promise deliveries for April.

The Citroen is decidedly a light car, of French design, with a lot of American ideas incorporated into it. The engineer responsible for its production was for a number of years responsible for a French light car which had local success but was not built on a big enough scale to become known far from Paris. When he linked up with Citroen, the engineer had to think in big numbers, with the result that he had to pay a lot more attention to production methods than was ever before thought necessary. Citroen has not yet got into production, but he claims that in a few months his factory will be able to show points to the best in America.

The engine is a four-cylinder one, 65 by 100 mm. (2.5 by 3.9 in.) bore and stroke, and the car is intended for people who will consider operating costs very closely, and with gasoline costing $1.20 per gallon and likely to continue at this price for some time there is no room for big bore engines if the work can be done equally well by a small engine.

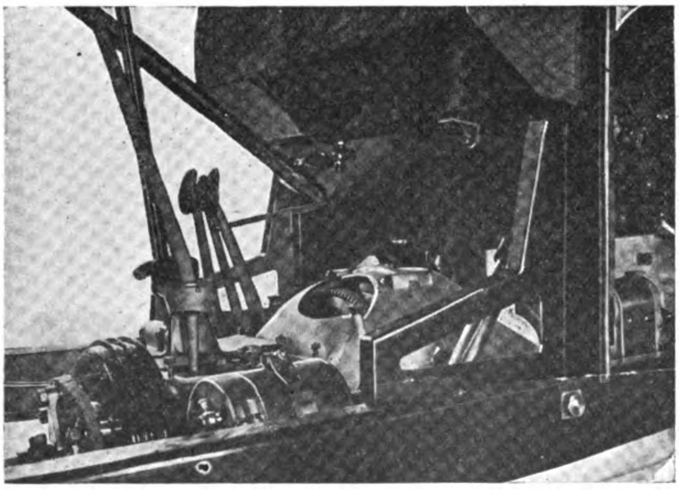
The detachable cylinder head has been adopted partly because of the facility for carbon removal, but more largely on account of ease of production.

Left-hand steering with central control has been decided on entirely on account of simplification in construction and assembly.

Michelin steel disk wheels have been adopted as standard. These are fitted with tires of 710 by 90, and give a clearance of 8½ in. Wheelbase is 100 or 112 in., with a track of 46 in. A speed of 40 miles an hour is claimed for this car, with a gas consumption at the rate of 31 miles to the American gallon.

This car is being put on the market as a two or four-seater touring type, also two or four-seater closed model. Present price for the fully equipped four-seater is $1,470. It is intended to use the same power plant in a heavier chassis as a taxicab and as a 1000 lb. truck.

Although the engine, clutch and gearbox form a unit, Citroen has not adopted the American method of cast-



All pedals are attached to the top of the gearbox in the Citroen. The clutch housing has been cut away to show the gear on the flywheel

ing cylinder and upper portion of crankcase in one. The cylinder block is mounted on an aluminum base chamber divided horizontally, the lower portion forming an oil pan. The clutch housing and gearbox are separate aluminum castings bolted up to the engine crankcase, the unit thus formed being attached in the frame at three points. In doing this the crankcase bolts to the two side members, and at the front there is a trunnion attachment to the first transverse frame member. Within a very short time engine base, clutch housing and gearbox will all be produced by die casting, the big production contemplated justifying this initial expenditure.

Provision has been made for the withdrawal of the entire power plant without disturbing any portion of the body. After the radiator has been taken off, the forward universal disconnected, and such auxiliaries as gasoline line and exhaust pipe detached, the entire unit can be pulled forward, passing under the dashboard, and lifted free without touching the body.

L-Head Engine Type

There is no great departure from standard practice in the engine. It is of L-head type, with valves on the right-hand side. The crankshaft is carried in two plain bearings, which are lubricated under pressure by means of a pump in the base chamber.

The magneto is placed fore and aft on the valve side, and the electric generator in a similar position on the opposite side. The two, together with the camshaft, are driven by means of helical gears.

Cooling is by thermo-syphon water circulation through a gilled-tube radiator, the inlet pipe being branched from the two sides of the radiator and entering the cylinder jacket on its forward face. There is no fan, although a fan bracket is carried in case it should be necessary to use a fan in tropical countries. The engine is declared to develop 18 hp. at a maximum speed of 2100 r.p.m.

The Solex carbureter fitted has the distinctive feature that by unscrewing one nut the whole device comes to pieces, exposing float, counterweights, jet and tube.

All the electrical apparatus is built in the Citroen factory, and comprises a 6-volt, 10-ampere dynamo; the battery is carried inside the chassis, and the electric starting motor is to the right of and alongside the gearbox.

The clutch is single-plate type, lined with fiber fabric and running dry in a closed housing.

There are three forward speeds and reverse, with oscillating type of change speed lever mounted directly on the gearbox cover.

Hotchkiss drive has been adopted, with a rubber disk coupling at the front and a plunger type universal at the rear. Final drive is by means of Citroen herringbone gears.

Quarter Elliptic Suspension

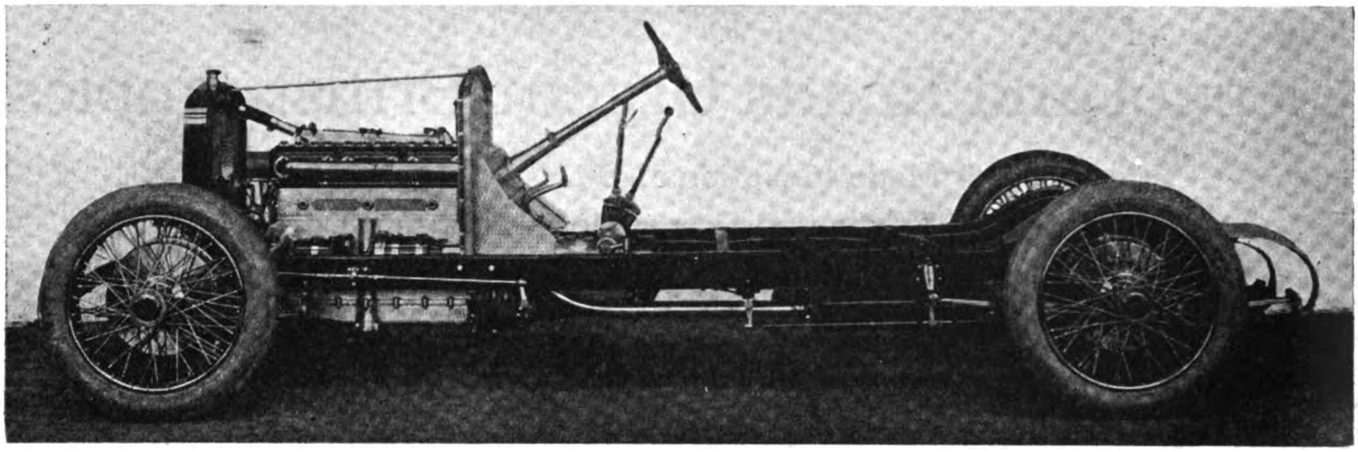
Undoubtedly the most unusual feature of the car is the springing. At the front this consists of quarter elliptic springs bolted under the frame members and attached to the straight axle. At the rear double quarter elliptics are employed, these being attached at their forward end outside the frame members, and at the rear one is mounted above and the other below the axle housing, the attachment being by means of a forged bracket fitted on the axle tubes and heavy and hardened and ground bolts provided with adequate lubrication. This rear suspension forms a parallelogram which assures the axle being kept parallel to the chassis at all times, and, while reducing the unsprung load, gives an ideal construction for transmitting the drive and the torque through the springs.

New Delage Six

DELAGE has stepped out of the light-weight, medium-powered car class into what may be termed the luxury field, by the production of a high-grade, fast, six-cylinder model. Louis Delage has been working toward this class for a number of years, and although he has specialized in cars of medium power his experiments and his extensive racing have been carried out with a view to the production of a really high-class job. The war has given the opportunity desired, and after building several hundreds of his new six for the French army, he is now putting it on the market in a modified form.

Unit Power Plant Design

The engine, a block six of 80 by 150 mm. (3.1 by 5.9 in.) bore and stroke, is rated at 24 hp. but develops 70 hp. at 2000 r.p.m. It forms a unit construction with clutch and gear-



Chassis of the new six-cylinder Delage

box, is carried in a chassis of 135 in. wheelbase, fitted with front and rear wheelbrakes and capable of a speed of 70 miles an hour with touring equipment, and 65 miles an hour with closed body.

The speed of the six-cylinder Delage with full touring equipment is easily 70 m.p.h. With closed body the car can do 65 m.p.h. Gas consumption is at the rate of 14 miles to the American gallon. During the war it has been necessary to make frequent trips from Paris to Grenoble, a distance of 360 miles. Driving fast, it was found that an average speed of 43 m.p.h. could be made for the entire distance, including all roadside stops, with a gas consumption of 11.2 miles to the gallon. Fixing the maximum speed at 47 m.p.h., this speed never to be exceeded however tempting the road might be, the average worked out at 37 miles an hour, and gas consumption averaged 14 miles to the American gallon. This indicates rapid pick-up and high speed on the hills, for a portion of this road is through a mountainous district.

Delage is building this chassis in three wheelbases, 132, 136 and 145 in., to take respectively a runabout, a touring body, and a big closed body. Track is standard 56 in. for all. Final gear ratios are 3.6, 3.4 and 3.27 to 1. Detachable Rudge-Whitworth wheels are standard.

Interchangeable brakes are fitted on all four wheels. The front wheel brakes are built under Perrot license, Perrot being a French engineer who first specialized on front wheel brakes and secured patents on many of their details. He first applied his brakes to the cars built by the now defunct Argyll company. Delage used these brakes for 2 years on his racing cars and was so satisfied with the results that he decided to apply them to his touring models. Front and rear drums are the same size, diameter being 15½ in. and width 2.3 in. The four brakes are operated together by the pedal and at a speed of 60 m.p.h. are capable of bringing the car to a standstill in 100 yd. This means that 60 m.p.h. is a safe speed so long as the driver has an open stretch of 120 yd. ahead of him. There is a hand brake on the gearbox.

The L-head engine type has inclined valve stems, intake manifold cast with the cylinders, and exhaust manifold separate. The layout has been designed to give complete accessibility. Thus the pump and magneto are driven from a transverse shaft; the electric generator and the starting motor are fore and aft on the left side, just below the valve stem chamber; on the right the two Zenith carbureters are bolted up direct to the cylinder casting and are fed by the vacuum system; on the same side, and at the forward end of the engine is the combined breather and crankcase filler, and at the opposite end is a three-way tap which gives level, overflow and emptying of the base chamber. The crankcase webs

Benzol and Roads Urgent British Topics

Efforts Being Made to Nationalize Gasoline Substitute As a Home Production Proposition—Notes on Car and Truck Output

Special London Correspondence

LONDON, March 7—Just now the two topics most interesting to the British motor trade and prospecting motorists are the benzol situation and the future of the roads. As regards benzol the interest centers in efforts being made to nationalize it as a fuel of home production and to prevent its handling becoming a monopoly of the oil and gasoline trusts.

I made reference to the matter in a former note, but since then a meeting has been held under the auspices of the new National Benzol Association at which some interesting information was disclosed relative to the development and present position of the British benzol industry.

At the close of the war British gas companies were producing 11,000,000 gallons of benzol a year and the annual output of the coking ovens amounted to 21,000,000 gallons—a total of 32,000,000 out of the estimated total of 200,000,000 of motor spirit annually required by Great Britain.

Gas companies, by a slight diminution of the calorific value of gas, it was urged, would increase their annual production of benzol to about 40,000,000 gallons if the authorities permitted, inasmuch as its deprivation only affects the quality of gas to the extent of 5 per cent. It was stated that in a few weeks some twenty London motor buses would be running on a mixture of 25 per cent benzol and 75 per cent duty free industrial alcohol.

National Control of Industrial Transport

As regards the future of British roads, interest centers in the government's new scheme under a bill now before the legislature entitled the Ways and Communications bill for nationalizing practically everything connected with industrial transport within the country, including also the electricity supply in bulk. Many motorists are opposed to the control of the roads being vested in this body; this opposition being accentuated probably because of the almost certainty that the railways will be nationalized, and it is feared that a single body with an ex-railway officer at the head, and vested with powers over transit by rail, roads and internal waterways, will be dominated by railway interests.

Personally, I do not share these fears, because the bulk of people recognize that the interests concerned are not intrinsically antagonistic, but complementary one to the other, and, also, as far as motor transport of roads is concerned, because the government is committed to a national electricity scheme which when developed will involve a wholesale electrification of rural districts and almost certainly, too, will lead to a wide use of electricity about farms for lighting, traction of implements over the land and of produce to the markets, or at least to the nearest convenient railhead.

Ideas embodying this form of development find more favor now than former schemes for light or roadside railways after the Belgian model. Our experience with this class of construction is that it is expensive relative to its capacity and benefits, and of course any rail service must be circumscribed and limited as compared with road transport.

Generally speaking, the chief drawback to British internal betterment has been too much parochialism. For instance, we have 2100 separate roads and highways authorities in the country, and the proposed measure referred to is intended to sweep the lot into a single control with departmental administrators.

London Motor Buses

The Associated Equipment Co., Ltd., of Walthamstow, London, is the largest producer of gasoline truck-chassis in the country, and is now listing its products to the public. At present it is building a 6000-7000 lb. truck-chassis which is largely a development of the famous B type chassis of the London General Omnibus Co., whose headquarters are at Walthamstow. The A. E. C., the short title of the chassis company, is about to introduce a 4000-5000 lb. chassis, which will place the company in a very favorable position to compete on the truck market at home and in the British Colonies.

As builders of the L. G. O. bus-chassis this company will shortly be introducing a new model which, it is expected, will be about 1500 lb. lighter than the present bus chassis. This weight reduction is largely the outcome of the action of the local street traffic authorities in insisting that the fare must be reduced. It happens fortuitously that this change is being made at a period when it is necessary to replace the L. G. O stock of buses, which had become depleted from 2742 before the war to under 2000, its present number.

During the war 230 of the 1093 buses sold to the government have been replaced. It is stated that it will cost over $13,875,000 to replace the entire number to the pre-war standard of 2742 vehicles, this estimate being based on an allowance of not less than $2,000 per vehicle above the pre-war price.

The A. E. C. output resources are up to 140 vehicles per week, but probably this number will be increased when the factory has been completely modernized, or, to be more correct, Americanized by the Works Director, Samuel Wallace, who came to us from the General Electric in America.

The Dunlop Rubber Co.

The Dunlop Rubber Co. is probably the only British tire making company which owns its own tire fabric making plant. For years Rochdale in Lancashire and in particular the mills of John Bright & Co. have supplied tire fabrics, but some time back the Dunlop interests decided to be their own exclusive providers of fabrics.

They are spending about $7,500,000 on a new mill for weaving the tire fabric. It will employ some 3000 workers.

A Birmingham paper states that the local Wolseley works are in a position to produce 20,000 cars yearly

as a result of war-time developments in the factory buildings and plant. Almost 2000 vehicles a year was the reputed pre-war capacity of this factory, which shared with Daimler at Coventry the credit of having the largest organized potential output capacity among British factories. At present reputed prices it may be doubted if there will be anything like so large a demand for Wolseley and other high-priced models, as at present listed, but the Wolseley interests are associated with the production of a neat light car—the Stellite, which is fairly popular and if concentrated upon could readily find purchasers at the comparatively high prices asked for vehicles of its class. I have not found many persons hopeful of there being any large market here for average British cars at present reputed prices. The fact is the cost of living and taxation won't leave much for motor car buying at present prices.

It is rumored that Wolseley will shortly be declaring for a world trade on a quantity production basis. My informant states that it is likely that three sizes of cars will be listed, to suit the three chief categories of buyers and class of body most in demand. Of these the medium grade car is likely to be the chief attraction, provided that the price of materials and labor charges do not advance. The Wolseley factories now cover about 100 acres, and having regard to the company's already notable decision to concentrate on cars to the exclusion of trucks, which before the war were a joint line in the much smaller factory than has now to be filled, it seems obvious that will only be possible to meet the situation with a car which shall eclipse all competition by combining value and price on a scale hitherto not attempted in Great Britain. What that price will be can only be conjectured now, but it must not exceed $1,750 to permit of the British colonial trade being recovered. Moreover, it will be necessary to set aside a much larger capital in spare parts which must be stocked where most convenient for distribution in the territories concerned. The war has taught our makers lessons on this score, chiefly because of the Aircraft authorities insisting on a fixed percentage of spares—practically so many complete engines—per batch of engines ordered. The alternative course to cheapen manufacture here, of course, will be to manufacture of the larger colonies, after the model of Fords, but this, of course, demands putting down capital in assembly buildings and plant. The new 1919 Buick Six has just arrived at the London premises of General Motors. It was imported under license of the Board of Trade and is one of the first American models to arrive. At the price it is hoped to be able to list it, even allowing $500 for the cheapest body to be fitted her, and allowing also 33 per cent ad valorem for import duty, I doubt if any British four, let alone a six, in the corresponding category, will be found to approach this new Buick for real value.

It is reported that two of our oldest British motor companies are joining interests. The companies concerned are White & Poppe, Ltd., engine specialists, Coventry, and the Dennis Co., Guilford, makers of trucks. Dennis came in from the cycle trade twenty years ago, passing through the stage of motorcycle making to car and truck making, but more recently have concentrated exclusively on trucks. They were pioneers as users of the worm-axle drive for trucks at a time when only the Lanchester-Hindley hour-glass form of worm was being used for cars, and have consistently used the worm-axle and also the engines of the White & Poppe Co.

While this fusion is quite in order so far as it concerns these two companies always associated in the way stated, another issue is raised by this sort of combination. When the Bosch interests here were taken over by a subsidiary company, one of the Vickers group, some people in the trade looked askance at it on the score that now the Vickers Co., as owners of the Wolseley car business, were going to enter into competition with their own likely customers for magnetos, etc.

Timken Solving Difficult Production Problem

Daily Production Conference and Use of Simple Chart Keep Manufacture Up to Schedule

By J. Edward Schipper

PART I

TIMKEN axle production presents a problem in manufacture which differs materially from that ordinarily encountered in an automobile factory or in any plant where but two or three models, at most, are produced.

The Timken-Detroit Axle Co. builds a great many varieties of axle, and since the number of each variety is apt to change suddenly, being greatly decreased or increased in accordance with the desires of the manufacturer of the finished car or truck, it has been necessary to lay out the plant so that the greatest amount of elasticity prevails as regards the handling of the axles in such a way that the production stream is constant, whether the number of one model drops off or increases in production.

To meet this situation, the progressive methods, such as would be provided by a traveling chain or some other arrangement of a similar nature, would not be possible because the forms of the carriers to handle the different parts would have to be changed to take care of the different models coming through.

Since it is not possible at any time to calculate for a long time ahead the number of a particular model coming through, this phase must be eliminated, and a method has been designed to overcome difficulties of this nature. Timken axle manufacture is strictly a group or departmental proposition.

All axles have similar parts. They all have housings, carriers, tubes, shafts, and in the case of front axles, they have knuckles, etc.

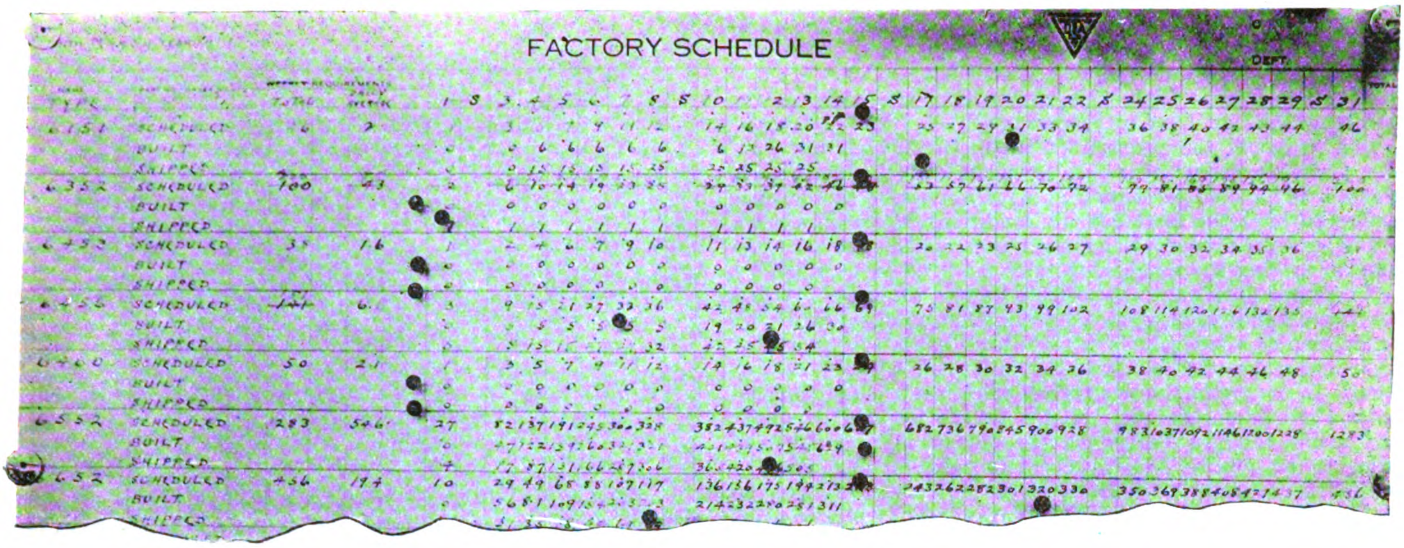
Based on this idea the Timken factory is divided into departments to coincide with the common parts possessed by axles. There are a housing department, a carrier department,

A good example of the segregation of departments. This is the axle housing department and, as will be noted, work on all types of housings is passed through here

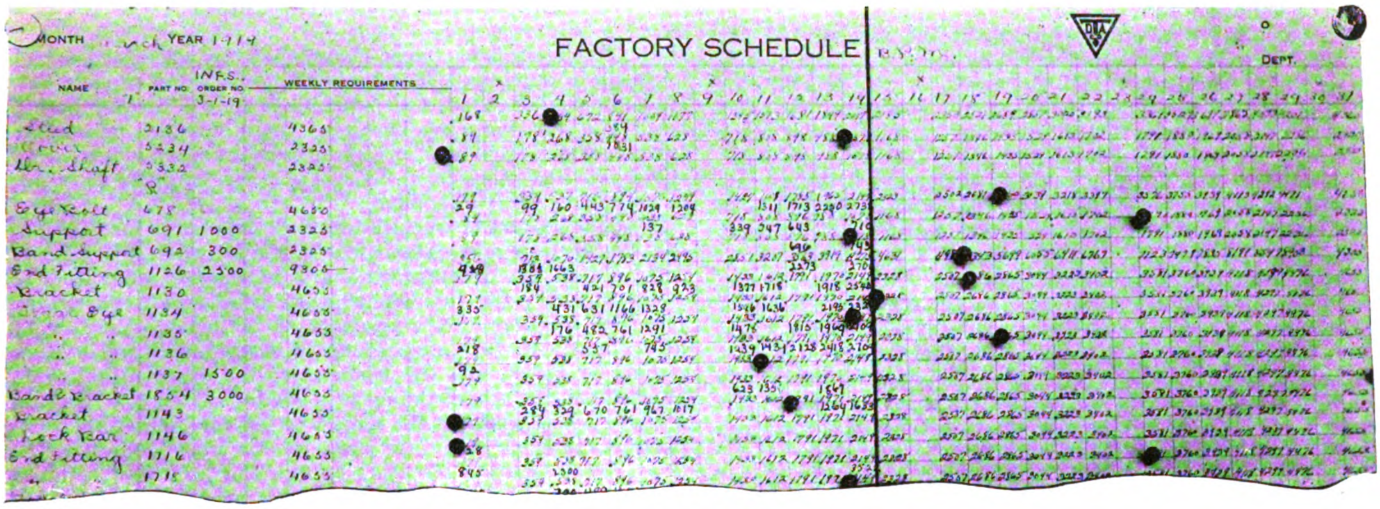
and other departments grouped similarly for rear axle manufacture, and for the front axle manufacture there is a knuckle department and other departments for front axle parts.

Distributed all through the factory, which comprises a large number of buildings, varying in size, are these departments, each specializing on one particular part of several models of axles. There may be going through each department a varying number of each axle every day. If there are twenty-five different model axles being produced in this particular plant, then through each department there will be twenty-five different styles of parts unless the parts happen to be identical for different models of axle, as sometimes occurs.

Forgings for all types of axles are handled in the same forging shop. This view gives an idea of some of the many types of forgings handled in this shop. A number of the various front axle forgings are shown in the foreground

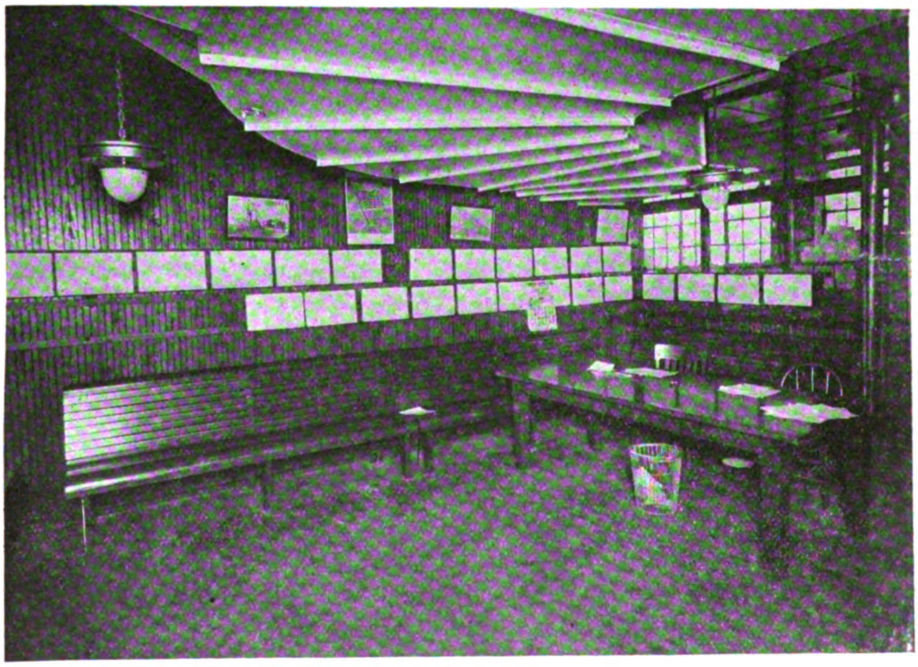


Factory schedule pinned on wall of production manager's office. The solid vertical row of pins under date of March 15 shows the present date. These pins are moved along one column every day. The other pins indicate the dates corresponding to the number shipped or built



This chart shows the department schedule. A rubber band slipped around the card indicates the date (March 15), and all pins to the left of this line indicate jobs behind schedule; all pins to the right indicate jobs ahead of schedule

The foreman whose department has held back production is voted the "goat"



Conference room in which the production conference is held. The foremen of all departments gather here daily and the factory schedules are gone over

It is evident that in order to keep up with production a department will have to run ahead and store some of its production in finished stock, or else it will have to vary its machine set-ups quite frequently in order to take care of the different jobs that have to go through.

This presents the problem of production which the Timken planning department has to meet, and the manner in which it is handled presents a great object lesson of efficiency under, perhaps the most difficult conditions of manufacture.

The general production manager is supplied with an order number stating the number of axles required on that job for as long time ahead as it is possible to give the order. Working from this information, the production manager plans his production on a monthly basis. He then divides this on a daily basis and makes that quantity the daily quota of each department. In the production manager's office is a production chart upon which is entered the number of the job and its name, and under columns headed by the date are the number of axles to be produced each day. In this factory schedule under the current date there is placed a vertical row of black-headed pins, and under the daily dates is placed a pin on the date corresponding to the number of axles produced and another showing those shipped.

Before the parts get into the finished part stockroom they are given a careful inspection, so that all parts drawn from the finished stockroom are ready for manufacture and have been certified by the inspection department

Explanation of Production Chart

The explanation is:

If a certain job is going through at the rate of 100 per day and 100 axles should be finished on the first of the month, 200 on the second, 300 on the third, 400 on the fourth, etc., and the date of the month is the tenth and only 500 axles have been produced and 400 shipped, the vertical row of black pins would be under the tenth, indicating that it is the tenth of the month. The red pin would be under the fifth, indicating that production only up to that day's schedule had been completed, and a yellow pin under the fourth showing that shipments were only up to those scheduled for the fourth.

A glance at the chart would show that on this particular job the production is 5 days behind. On the other hand, if by the tenth 1500 axles had been produced, the red pin would be in advance of the black line under the fifteenth; so that production is 5 days ahead, or if there is enough of that axle in finished stock to complete the month's order, the pin might be out to the end of the month, showing that the order was complete on that axle for the month.

Thus the chart tells the production manager at once just what jobs are lagging behind schedule, which are even with schedule, and which are ahead.

The same scheme is followed in the departments. Each has its chart with a black line formed by a row of black pins, or a rubber band slipped around the chart at the current date. Each has the orders listed upon the chart and pins showing the date corresponding to the amount produced indicated by red pins. All red pins to the left of the vertical black line indicate jobs that are behind; all those to the right indicate jobs that are ahead and tell the foreman of that department immediately what jobs to push and what jobs upon which he has a safe margin. These production charts telling the status of the complete axles in the production manager's office and of the different parts in the foreman's office of each department handling that part furnish the key to the entire production situation in the factory.

Hold Daily Production Conferences

Every day a production conference is held. After the day's work is complete each foreman takes his chart to the conference room, where it is hung upon a hook designated for it, as shown in the illustrations. As these boards are hung in place they form a row around the conference room which indicates the condition of any job at a glance. The foremen go over the charts, one by one, and thus readily see what condition of affairs exists in other departments, and they then get an estimate on the entire situation and know what to concentrate upon.

If a job is exceptionally late the foremen of the departments in which the pins for that job are lagging are called upon to explain why they are not up to schedule. If it is because material is not at hand the follow-up department is called in to explain why they have not secured the material. If the follow-up department shows that the material has not as yet been purchased, it is up to the purchasing department. If, on the other hand, the material is in the factory but is lying idle for want of machines, the production managers take machines from a job which is in advance, as indicated by the chart, and place them upon this order, in order to hurry it up and bring it into line.

A bonus system is worked out so that lateness on the part of a department may cause a cut in the bonus, and it is quite certain that the foremen who are well up in advance are going to hurry the foremen who lag behind on a particular job, thus threatening the payment of the bonus, or reducing its amount. In fact, at the end of every month an election is held by ballot, and the foreman of the department which has delayed the others the most is elected as the goat, and on a board which contains the names of the foremen of each department a goat is pinned opposite his name and remains there for a month. Needless to say, the goat is careful to remove the symbolic animal from his name on the succeeding month.

This gives the follow-up phase at the Timken plant. There is another phase, however, which is of equal importance and which will be discussed in Part II.

Book Review

AERONAUTICS MADE EASY, by Capt. W. A. Aston. Published by Iliffe & Sons, Ltd., 20 Tudor St., London, E. C. 4, England. Price, 4/6d.

The remarkable progress which has been made in aeronautics during the war has brought the airplane almost to the commonplace level of the motor car, but owing to the secrecy with which it was necessary to veil this development during the war, general knowledge of aeronautics has not kept up with the progress of actual practice.

Students of aviation, and all who take an intelligent interest in flying and flying machines, will therefore welcome the new text-book on the subject, which has been prepared by Captain Aston. The author deals with a fascinating subject in a very interesting manner. His object has been to show how an aeroplane flies, rather than why it flies, and he accomplishes this by first explaining how the underlying principles of flight are applied, and then giving the details of the airplane itself, and showing what functions each part is called upon to perform.

Among the subjects dealt with are the influence of streamline formation on speeds, the shape and angles of planes and other surfaces, the stability, the functions of the propeller, loading and control, air-cooling and water-cooling, etc., The advantages and disadvantages of pusher and tractor models are set out, and the capabilities of the various types compared.

Industrial Development Depends Upon Partnership of Capital, Management and Labor

By Harry Tipper

AT a meeting of industrial engineers, which occurred in this city 2 days ago, a great deal of the time of this convention was spent in the study of the labor question and the human side of industry. This is as it should be, and it is an encouraging sign when engineers turn from the examination of machine production, motion study, and other items of a like mechanical character, to the study of the most important factor in production, the human being, and to the complex forces which are behind the difficulties observed in present production.

Of the papers which were presented, the paper by C. E. Knoeppel, of C. E. Knoeppel & Sons, New York, contains so much which is of value to the study of present conditions and the means that ought to be taken in order to overcome the difficulty, that we are quoting liberally from this paper, the whole of the paper occupying too much space to give it in full.

War Due to Workings of Progress

"Was this all an accident? Was the ambition of one man, or one class, or one nation to blame for this world catastrophe? Yes, but only indirectly. As I review the past, it seems to me that the world war was the result of the workings of a law of progress, which has been in evidence since the beginning of time, a law to the effect that while progress is ever upward, it is never in the form of a straight line, but a series of curves or cycles, made up of four steps:

"1. Conflict. 3. Refinement.
2. Development. 4. Retrogression."

"In life we find a conformity to the law above mentioned. Study the child, his relation to his parents and his teachers, his combative and sometimes savage nature, his days of the gang period, his recklessness and tempestuousness in his first years of school life, and you will find an excellent illustration of the conflict period in human progress. The youth becomes serious. He studies, goes through college, and begins his career in business. This is his development period. Then follows the period of refinement, in which the man builds well on the training he receives, becomes successful in his work, perhaps amasses a fortune. Finally at the height of his power, he begins to wear out, his energies begin to fail, and he is in the retrogression period, from which none of us can escape."

"What is the world situation to-day? People tired and weary after years of fighting; depleted treasuries; enormous debts requiring years, generations perhaps, to pay off; a world hungry for the food necessities of life; the most gigantic destruction of property the world has even seen, making rebuilding a task which staggers the imagination; millions of crippled, blind and helpless who must be taken care of in some manner; other millions who were directly or indirectly engaged in warfare, suddenly without occupations or immediate means of earning a livelihood.

"To fill depleted treasuries, feed the hungry, pay heavy taxes, replace and rebuild destroyed and damaged property, and care for the sick and helpless, money in huge quantities is going to be needed, and money can only come through trade at home and abroad. The nation that can win the most trade will be the most prosperous. The one that is the most efficient will win the most trade. This applies to nations, to industries and to plants in the same industry."

Something Certainly is Wrong

These paragraphs indicate Mr. Knoeppel's basis for argument, and while there might be some controversy as to his statement that these things are economic in their character, nevertheless, the conditions which he describes are here, and his examination of the subject is informing and suggestive.

Much more suggestive, however, in connection with the present condition, is the statement in respect of industry and the fact that there is something wrong with our industrial system from an observation of its present results, not only in connection with the warfare and dissatisfaction between the different departments of industry, but in connection with the final result of this whole industrial development which are stated in his paragraphs:

"Something is certainly wrong, when prices should be on the continual advance, in an age of the most improved machinery, the most advanced shop practice, the best that can be devised in the way of management methods, and the latest in industrial devices. Something is wrong with conditions which makes the dollar less in value to-day than a year ago an dmuch less to-day than it was five years ago.

"Trace if you will the transition from basic raw materials to the product in the hands of the consumer. A raise in wages at the start increases total cost, on which profit is figured, so that the concern which purchases the product, *as material*, pays both for the raise in wages and the profits on the raise as well. The concern that buys this material is forced to raise wages, we will say, and the next man who buys this product, as material, not only pays for the extra cost, a slabor and profit, of the first step in the progress, but the second as well, it does not require much imgaination to realize that by the time the ultimate consumer gets the finished product, it is loaded up with a series of consistent raises in wages and additional profits.

The User Pays the Bills

"The user pays the bill. Who is the user? Worker, manager and capitalist. Which is the largest class? The working class. Consequently, while the worker receives more money in wage increases, he is no better off; in fact, worse off, because prices increase in greater proportion than his wages increase, due to the successive stages through which the work goes from raw material to finished product, and the addition of profit to total cost, the cost including wage increases. The load, therefore, falls on the shoulders of the ones who, while causing the conditions to a great extent, are the least able to bear it. Does labor realize this? It does not."

There is an interesting point for manufacturers to consider in connection with their responsibility for the

outlook of the worker, a responsibility which has been considered very rarely in our industrial work, and a responsibility which can only be discharged by measures of education that have not been considered up to the present.

"I was recently discussing the business situation with a Pittsburg manufacturer. He was protesting most strenuously because his labor was producing less and costing more than ever before, and that it would be a good thing if we had some bad times to teach labor a lesson. I asked him what he had ever done to disabuse the minds of labor as to over-production, the introduction of labor-saving machinery and the like. I asked him further what his fellow manufacturers had ever done to place before the workers fundamental principles of 'industrial economics.' He had to admit that what he had done was conspicuous by its absence. Further, I wanted to tell him that he needed to take the beam out of his own eye before removing the mote from that of his brother. Capital has much to undo before it can go to Labor and teach it economic truths."

Getting down to the development of the argument, as it relates to present conditions, there is a concise statement which we have quoted below as to the fallacies which are common in the ranks of labor management and capital, and fallacies which must be eliminated if we are to work out the industrial system so that it will be permanently of advantage to all parties, and so that the present strife will be decreased instead of increased.

These fallacies, placed alongside the things which must be done in order to offer the solution of the present difficulties, give a pretty clear picture of the situation, and indicate that thoughtful men in industry are studying these subjects without the atmosphere of prejudice which has prevented an understanding of their significance heretofore.

No Room for These Fallacies

"Here are the fallacies which must have no part in our new industrialism:

"A—*On the part of labor*—(1) That production should be retarded and the introduction of labor-saving machinery frowned upon and fought against, in order to make more work for more people and guard against over-production.

(2) That it creates wealth and should therefore enjoy the fruits of such creation, the argument being that in the last analysis the products of industry are the work of labor.

(3) That Capital is opposed to it, because it gives it no say in management nor a share in the profits of industry.

"B—*On the part of management*—(4) That it is the boss and that its decision is final because responsible for results.

(5) That labor is commodity to be purchased according to the law of supply and demand the same as material.

(6) That it is only accountable to capital.

"C—*On the part of capital*—(7) That it is the controlling factor because it supplies the funds.

(8) That it has no further obligation beyond supplying the funds.

(9) That all the profits belong to it.

(10) That labor is opposed to it because of strikes and agitation.

"In this present era of conflict, of industrial unrest and general dissatisfaction, welfare plans, shorter hours, higher wages, union recognition, bonus and incentive plans, lower cost of living and the like are not going to satisfy the desires of the masses. These things without others, more important and fundamental, will leave them no better off than they were before, simply because they do not meet the economic demands, nor do they provide for self-expression of our people, for 'industrial democracy,' for a say in the conduct in industrial affairs, for real human development.

"The world wide tendency toward revolution is not due so much to desire for *political* changes, as to demand for *economic* changes. The clash we see on all sides is not aimed at kings, queens, emperors and presidents, but at unfairness, autocratic domination, inequality, unemployment and the like. What the masses the world over have in mind are houses, food, farms, clothes, jobs, wages, participation, representation in affairs and the like.

"Labor claims that it has had no say in the determination of shop rules; the rate of wages; whether labor shall be paid by the bonus, premium, differential piece work system or some modification of these; what shall be the time allowed for the perfromance of a task or the accomplishment of a so-called standard of efficiency; hours of labor; industrial education that should be given the workers; what methods should be established by which the workers might receive a hearing; what should be the basis of hiring and the grounds for discharging; what facilities should be provided for performing the work; whether bargaining should be collective or individual.

Real Partnership Necessary

"There will never be a real democracy in industry until we take steps to give Labor a say in matters that had to do with their side of things. If a partner in business, it should have a partner's voice. If there are two sides to a question, we will not get very far if we hear but one side.

"Labor wants its say in the conduct of affairs, both political and industrial. It should have this way. Capital and Management want the same say. They should also have it. The consent of the governed, representation in affairs, liberty and the pursuit of happiness, are the basic principles in political democracy, and they should and must become the foundation of the industrial democracy that will come sooner or later.

"If we want industrial democracy to be a living, breathing reality in our lives, then the only answer is that Labor along with Management, should be given a share in the conduct of business. I do not care so much whether the plan adopted is the shop committee or conference plan, the House of Representatives and Senate plan, Labor on Board of Directors plan, or some other plan, so long as opportunity is given for frank and open discussion of matters of mutual interest."

This discussion does not, of course, take into account the changes which must come about in the social and political aspect, in view of these necessities in industry. It does not take into account the result of the neglect by industry of this responsibility for educational matters in the primary schools for the proper development of housing and for its share of responsibility in political development.

It does, however, suggest some of the things which are necessary from an industrial standpoint, and it is important for its suggestions, and also as an indication of the tendency of the industrial conception at the present time.

Testing Pyrometers

THE pyrometer has three parts independently liable to error, viz., the thermo-couple, the measuring instrument and the lead wires. In testing pyrometer installations, provision should be made for the maintenance of a standard of temperature and for the convenient comparison of this standard with the instruments to be tested. The standard should consist of at least one platinum-platinum-rhodium thermo-couple previously calibrated to an official standard and a potentiometer. This standard may then be used for checking the secondary instruments, which should be done frequently enough to ensure against faulty calibration.

The standard couple should be used with a potentiometer, which is the recognized instrument for electromotive force measurements. It should be able to accommodate with full sensitivity both platinum and base metal couples. For use with the thermo-couples and potentiometers there should be a large electric furnace having a zone of uniform temperature extending at least 12 in., throughout which temperature variation is not in excess of 20 deg. Fahr. The furnace should have an internal cross section of not less than about 2½ in. in diameter.

Tests of Aeronautic Instruments

Need for Many New Instruments by Air Forces Led to Great Expansion of One Section of the Bureau of Standards—Classes of Instruments Required, and Some of the Difficulties Met With

By P. M. Heldt

THIS is the sixth of a series of articles prepared by Mr. Heldt from the research records of the Bureau of Standards in Washington. Previous articles have covered:

1—Dry Cell and Storage Batteries

2—Tests of Airplane Radiators

3—Altitude Engine Test Laboratory

4—Tests of Ignition Apparatus

5—Carbureter Testing

Additional articles covering other subjects will appear in subsequent issues.—EDITOR.

AT the time the armistice was signed the Aeronautic Instrument Section of the Bureau of Standards comprised about forty technical men, of which about one-half were on the Bureau staff while the rest were assigned to work in this section by the military departments. The enlisted men acted in the capacity of assistants.

While the section, as a separate branch of the Bureau of Standards organization, was established at the beginning of the war, it was really an expansion of a section which had been in existence for 6 years previous to the war and which concerned itself with altitude measurements chiefly in connection with ballooning and aeronautical work, but also in connection with mountaineering.

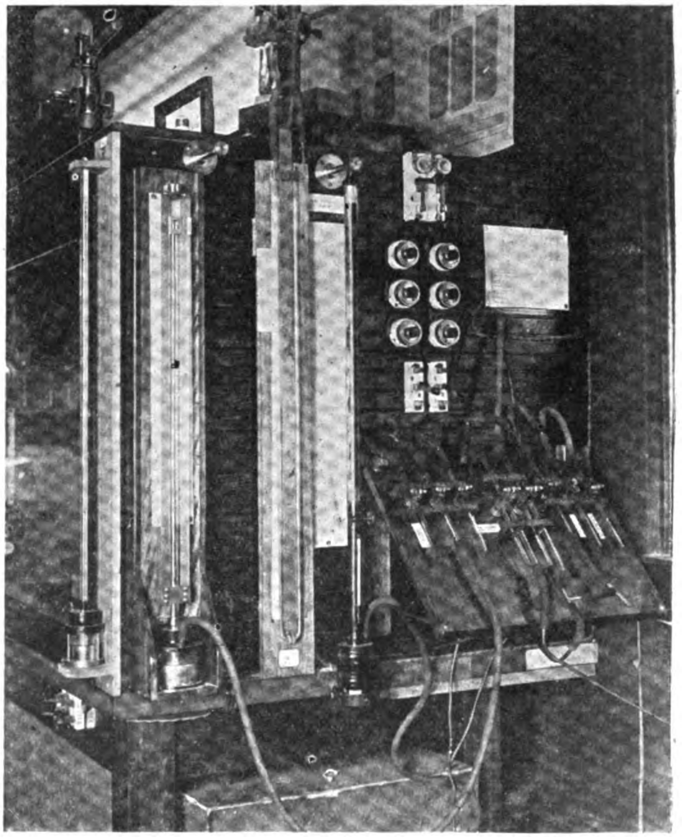
The men who conducted this work formed the only small group of technical experts in altitude measuring instruments in the country, and all of the altimeters used by the Army and Navy for 6 years previous to the war had been tested there. Another thing that rendered this section of the Bureau of Standards of considerable value to the Services when the war broke out was that these men were familiar with the status of the instrument industry throughout the country and were able to give the Army authorities data as to the capacity of the different instrument makers and their special experience.

Low Temperature Problems

While previous to the war the activity of this section had been confined to the development of altitude instruments, upon the outbreak of hostilities its field of activity was widened to include other aeronautic instruments. A special reason for entrusting this section with the work connected with the other instruments used in flying was that there are three particular difficulties with which all manufacturers of aircraft instruments have to contend and with which these experts of the Bureau of Standards had become familiar in their pre-war experience. These difficulties are due to the extremely low temperatures in the upper atmospheric regions, to the vibration of the engine and to the strong centrifugal force to which all instruments on an airplane are subject while banking. Provisions for compensating for the effects of these factors must be made in all kinds of airplane instruments.

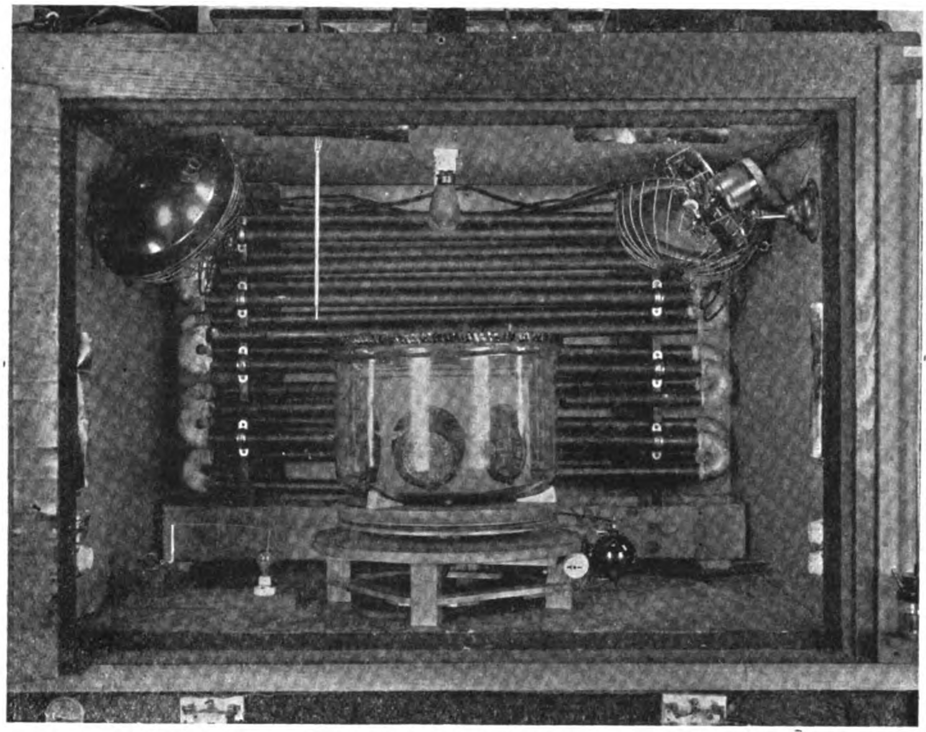
Following is a list of instruments that are commonly used on airplanes and in connection with which the Bureau has done research and testing work: Altitude measuring instruments, including the ordinary altimeters, recording altimeters and statoscopes, the latter used in balloons to tell whether these are rising or falling when it is desired to keep them at a constant level, and in airplanes under test when it is desired to fly in an absolute horizontal plane; rate-of-climb indicators; speed indicators, including instruments for determining the air speed or the rate of progress of the airplane through the atmosphere, which also tells the pilot whether he is going fast enough not to be in danger of stalling; tachometers giving the speed of rotation of the engine shaft; inclinometers, of which there are two types, namely, the liquid and the gyroscopic, which show the angle of inclination of the plane; pressure gages for showing the pressure on the lubricating oil and the pressure on the gasoline in the fuel tank; also gasoline tank gages and radiator thermometers.

As pointed out, the reason for the expansion of the altimeter section of the Bureau at the beginning of the war,



Mercurial standards and vacuum control board of aeronautic instrument test chamber

so as to take in other aeronautic instruments, was the fact that the technical problems arising from conditions of flight are the same for all kinds of instruments. The work which has been done by this section during the period of the war may be briefly summarized as follows:



Viewing the aeronautic instrument test chamber. Note that conditions of low temperature and centrifugal action are simulated

What the Section Has Done

1. The section furnished the authorities a list of manufacturers who would be in a position to take up large scale production of aeronautic instruments.
2. The section prepared technical specifications for the instruments which were to be produced. These specifications were in most cases adopted by the Army without any important changes so far as the technical features were concerned.
3. It tested a certain small fraction of all instruments delivered to see that no new sources of error were creeping in, and also tested samples of any new types of instrument to determine whether they were suitable for the work for which they were intended. Practically all contracts for airplane instruments were based on these tests.
4. The section developed some improvements in instruments and continually kept in touch with the manufacturers to help them to keep up their product to the standard of the specifications laid down.

The writer asked those in charge of this work whether any practical instrument had been developed for determining the absolute rate of progress of an airplane or its speed relative to the ground, and was told that there were two kinds of instruments for this purpose.

One kind is limited to use during the day and when there is no fog, when the ground can be seen. The use of this kind of instrument is based on a process of triangulation. The altitude of the plane being known, and an object on the ground being observed at the beginning and end of a certain interval, it requires only the solution of a problem in triangulation to determine the absolute speed of the plane.

The production of the other kind of an instrument, namely, one which will give the absolute speed of a plane when the ground cannot be seen has not been satisfactorily solved except in theory. It is one of the great outstanding problems in connection with aircraft instruments, as is also that of a non-magnetic type compass.

Quantity Production Methods

Owing to the rapidity with which results had to be obtained and the fact that our allies had been engaged in the war for over 2 years when we entered it, American manufacturers in the majority of cases contented themselves with the adaptation of British and French designs. In doing so, the Bureau with its extensive collection of foreign instruments, was of assistance.

When the war broke out here the only instrument in production in the United States was the altimeter, which is a type of aneroid barometer with a flat circular corrugated diaphragm. What developments were made in the United States in connection with instruments of foreign origin were mainly with the object of reducing the cost of manufacture.

All foreign instruments, and especially those built in France, involve a great deal of hand work, and the number of workmen in this country experienced in work similar to that required on these instruments was very limited, hence quantity production methods had to be worked out. The great trouble which has been experienced with aircraft instruments so far has been insufficient accuracy, which is largely a matter of quality of materials and adjustment of the different levers, cams, springs, diaphragms, etc. A case in point is furnished by the ordinary altimeter, the characteristics of which vary a great deal according to whether the diaphragm is flat or slightly concave or convex, when first assembled with the pointer standing at zero on the altitude scale.

Tachometer for Aircraft

AN illustrated description of the Morel electric tachometer, which has been largely used on German airplanes, is printed in *Der Motorwagen* for Dec, 10, 1918. It consists of the combination of a direct-current generator driven from the engine by suitable means and a moving coil galvanometer which is graduated in r.p.m.

In a magnetic field, formed by a number of magnets of high tungsten alloy steel, a drum armature revolves having a commutator and a number of spring contacts for collecting the current. The magnets are so constructed as to give a constant field. The transmitter in the latest design is driven through an intermediate shaft and flexible coupling. The whole of this transmitter is contained in a casing fitted with a special dust-proof bayonet-joint cap, while the armature is driven through gearing. For airships, motor boats, etc., the transmitters are fitted with bases.

The receiver galvanometer comprises the moving coil, wound on a pressed copper frame, and fitted with spiral springs which serve at the same time as current leads from the transmitter. The movements of the coil are transmitted by teeth to a pointer fixed to the indicator spindle.

German Engineering Standards

THE Council of the German Industrial Standards Committee has agreed to the following conditions becoming standard practice:

(a) The uniform temperature of reference for gages, etc., shall be 20 deg. C.

(b) In view of practical and theoretical advantages, the "zero" line shall be taken as the "limiting line" in connection with standard systems of fits.

(c) The S. I. (System International) and Whitworth systems of standard screw threads shall both be considered as standard.

The Lubrication of Motor Cars

Engine Lubrication Systems Dependent on Engine Load—Test Results from Crankcase Lubricant After 100 Hours' Use — Lubrication of Clutch Pilots and Transmission Boxes—Loss in Efficiency Due to Too Much Oil in Gear Case

By Capt. G. W. A. Brown

IN this paper, presented to the Institution of Automobile Engineers of Great Britain, Capt. Brown discusses chiefly problems in the lubrication of chassis components, as the lubrication of the engine has, according to him, received a great deal of thought and care, which cannot be said of other important parts of car mechanism. Each part is taken up in turn, and the problem of its efficient lubrication is discussed, various conventional practices being strongly criticised. The author does not believe in the common method of filling the transmission box and rear axle with grease, holding that oil lubrication is much more satisfactory. Only enough oil should be put into the cases so the gears will dip into it. Otherwise the efficiency will be lowered, owing to the unnecessary churning of the oil.—EDITOR.

WHEREAS a great deal of thought and care has been lavished on the lubrication of the engines of motor cars, the lubrication of the remaining components of the chassis, such as the gear box, universal joints, live axle, steering gear, etc., has been, to a great extent, neglected. As 90 per cent of the failures of cars are caused through wear, the author is emboldened to put before members of this Institution a few suggestions for the improvement of the oiling of these parts as an incentive to further experiments and to stimulate research, which would result in much benefit to both the manufacturer and the user.

The investigation of this question may be conveniently divided into six parts:

I.—The engine.
II.—The transmission, including:
- Clutch bearings;
- Flexible connection between clutch and gear box;
- Gear box;
- Universal joints, with particular reference to those of the Hooke's type;
- Propeller shafts and torque tubes;
- Back axle reduction and differential gear.

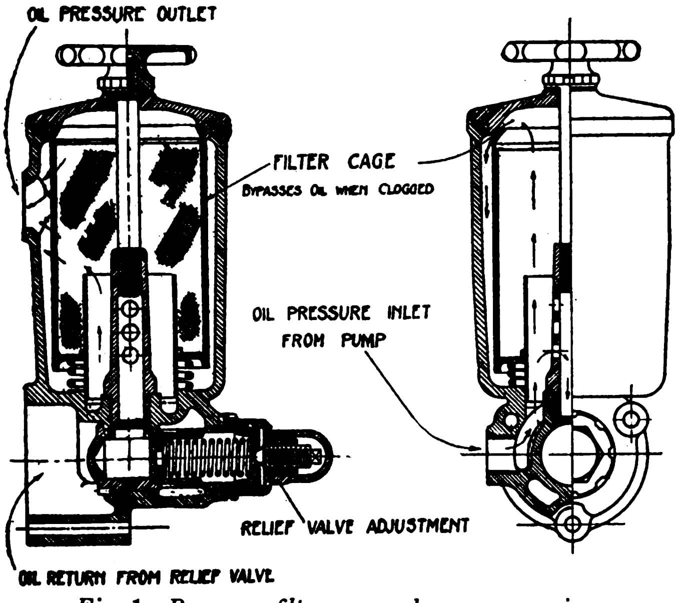


Fig. 1—Pressure filter as used on aero engines

III.—The steering gear.
IV.—The suspension system.
V.—Road wheel bearings.
VI.—Oil retaining devices.

I. The Engine

As previously stated, the engine is the only portion of a car in which the question of lubrication has been at all seriously considered. There are, perhaps, two exceptions to this generalization, and the author proposes to deal with them at a later stage. These exceptions are the Fergus car and the Marmon car.

There are two basic methods by which engines are lubricated:

(a) The pressure system;
(b) The splash system.

Other systems of lubrication are based on one or other or a combination of these two methods. The author does not propose to enter into any lengthy discussion of any of these systems, but will content himself with a few remarks upon some examples of the latest practice.

Two features of aero engine design may usefully be mentioned, namely, the dry sump and the pressure filter—the dry sump because it enables the oil to be kept at a lower temperature than would be the case if it were always stored in a portion of the crankcase; the pressure filter because its use permits of a very fine gauze without danger of starving the supply. Fig. 1 shows the general features of a type used in aero engine practice. The possibility of any reduction in circulation owing to the gauze becoming clogged is obviated by making it act as a by-pass valve in the manner shown by the right-hand view. With reference to the dry sump, it should be mentioned that this principle was first employed on at least two well-known types of British racing cars which competed in Continental races and competitions at Brooklands prior to the war.

Some designers have provided means of varying the oil supply at different engine speeds and loads, but all the systems of this kind that the author has come across are interconnected with the throttle. The tilting trough of the Knight engine is familiar to all of us. Messrs. Rolls-Royce adopt a method of opening a by-pass in the oil pressure pipe after a certain throttle position in order to give an extra supply of oil direct to the cylinders, while the Marmon oiling system is provided with a piston valve which is operated by the depression in the inlet pipe. At low engine speeds this piston valve uncovers a by-pass valve, so reducing the pressure throughout the whole of the oiling system. These devices are

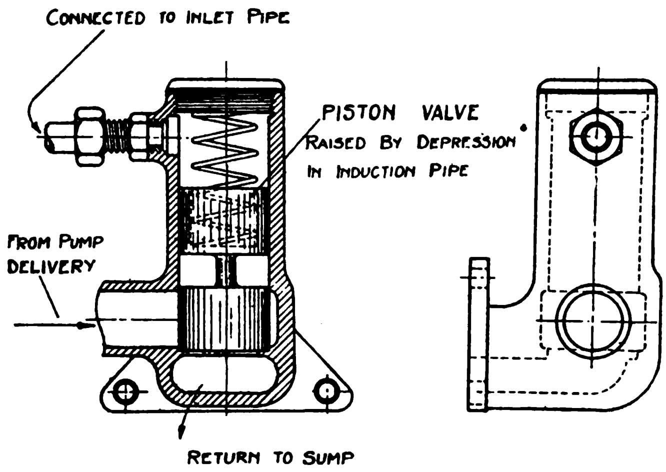

Fig. 2—Marmon oil pressure control valve

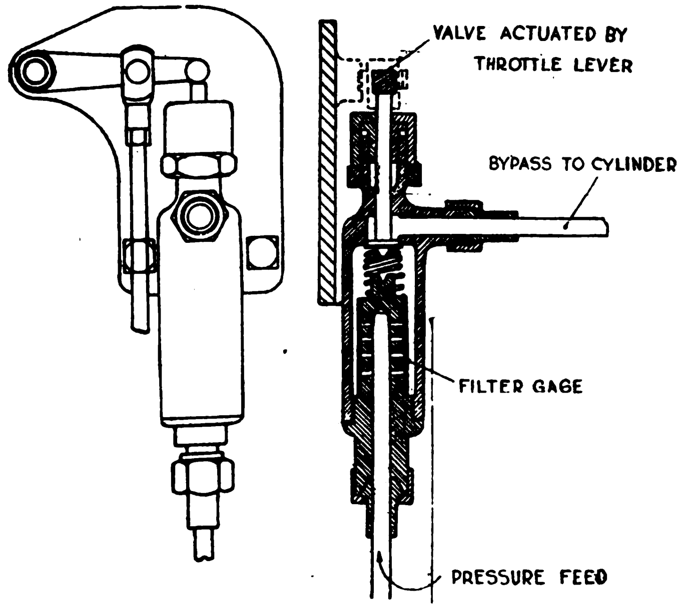

Fig. 3—Rolls-Royce throttle-controlled oil feed to cylinders

illustrated in Figs. 2 and 3. The author is not satisfied that any of these systems are correct, for the reason that it is possible to have extremes of engine speeds and loads for any given throttle position.

The usual practice in engine lubrication is to fill the sump with a given quantity of oil, which, according to most instructions, remains in use up to two or three thousand miles' running. It will be generally accepted that the longer the oil is used the thicker and darker it becomes, and, in order to ascertain the degree of deterioration caused by long periods of running, analyses were taken from:

(a) A standard proprietary brand of lubricating oil as delivered by the makers;

(b) A quantity of the same oil after 100 hours' running in an aviation engine of high power under full load.

There is very little difference in the actual test figures, but, as a slight reduction is shown in the co-efficient of friction, it is reasonable to suppose that this will continue to increase with the age of the oil. The original lubricating oil was of a yellow-green color and free from sediment, while after 100 hours' running it became deep black. On examination, this oil was found to contain a considerable quantity of carbon specks or particles in suspension. These particles, magnified fifty diameters, gave a dimension of 0.001 mm., and were so fine as to pass all the usual methods of filtering. We were able, however, to separate the carbon specks by filtering through 3 per cent Fuller's earth or with animal charcoal. The solid carbon particles so extracted amounted to 0.1 per cent, carrying also traces of iron and copper.

Samples of the oil were tested on a Thurston machine, and the general data and characteristics are shown in Table I. It will be noticed that the figures given prove the theory that the specific gravity is entirely independent of the viscosity, as, after use, the specific gravity has increased, while the viscosity has decreaed.

TABLE I

Analysis of Lubricating Oil Before Use and After 100 Hours' Running in Aero Engines

Specific gravity at 60 deg. F. before .... = 0.893
Specific gravity at 60 deg. F. after .... = 0.907
Specific gravity at 60 deg. F. used and filtered ...... = 0.892
Viscosity (Boverton Redwoods):

Standard refined rape oil	50cc.	Time, 7m. 7⅘s.	T. 60° F.
Unused oil	50cc.	Time, 49m. 20s.	T. 60° F.
Used oil	50cc.	Time, 47m. 16⅘s.	T. 60° F.
Used oil, but filtered		Time, 50m. 47s.	T. 60° F.
Unused oil	50cc.	Time, 9m. 5s.	T. 112° F.
Used oil	50cc.	Time, 7m. 35s.	T. 112° F.
Used oil, but filtered		Time, 10m. 31s.	T. 112° F.

Percentage of acid:
Before use .... = 0.211
After use .... = 0.250
Saponification figures:
Before use .... = 17.60
After use .... = 19.24
Co-efficient of friction:

Taken on Thurston's machine with white metal bearings

	Temp.	Revs. per Min.	Pressure per In.	Total Pressure	Co-efficient of Friction
Unused clean lubricating oil	50° C.	1,800	60	225 lb.	0.035
Dark oil after 100 hr. running	50	1,800	60	225 lb.	0.044
Filtered oil (carbon particles removed)	50	1,800	60	225 lb.	(0 041) (0.0380) 0.039

It is the practice of one well-known enemy engine builder to use a small auxiliary plunger driven from the main oil pump, which is continually drawing a supply of clean oil from the tank, and forcing it into the circulation along with the oil already in use, thereby making up for wastage and preventing, or, at least, reducing, the deterioration of the oil.

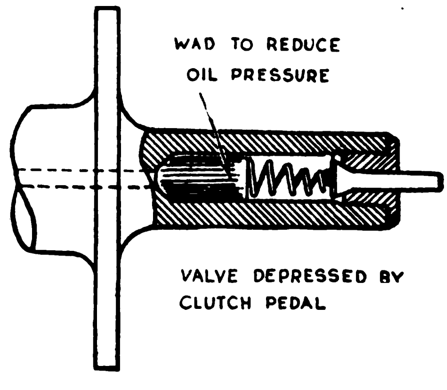
II. Tranmission

Clutch Pilot.—Lubrication of the clutch pilot is, with few exceptions, a matter of chance, or a Stauffer, which is much the same thing. In cars in which the engines are lubricated on the pressure system, however, some makers fit a non-return valve in the clutch end of the hollow crankshaft in such a manner that depression of the clutch pedal opens this valve and liberates a small quantity of oil. Fig. 4 shows such a device.

Flexible Connections.—Except, possibly, in engines and gear boxes of unit construction, it is necessary to have a flexible connection between the clutch and the first motion shaft. These connections are usually of the types illustrated in Figs. 5, 6, 7 and 8.

It is the author's complaint that there is no recorded case

Fig. 4—Non-return valve fitted in the clutch end of the hollow crankshaft to reduce oil pressure



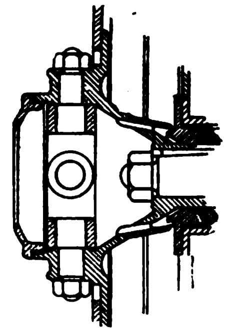


Fig. 5

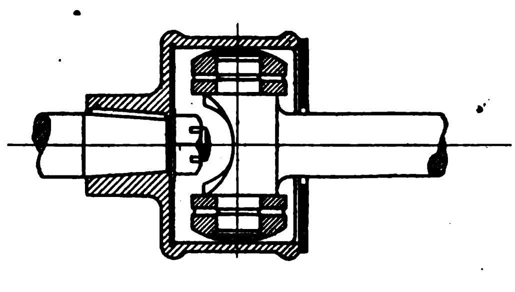

Fig. 6

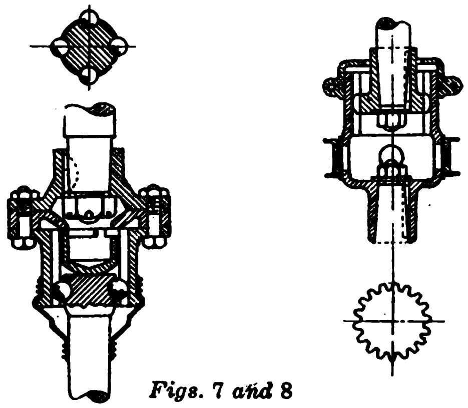

Figs. 7 *and* 8

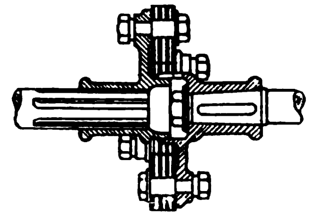

Fig. 9

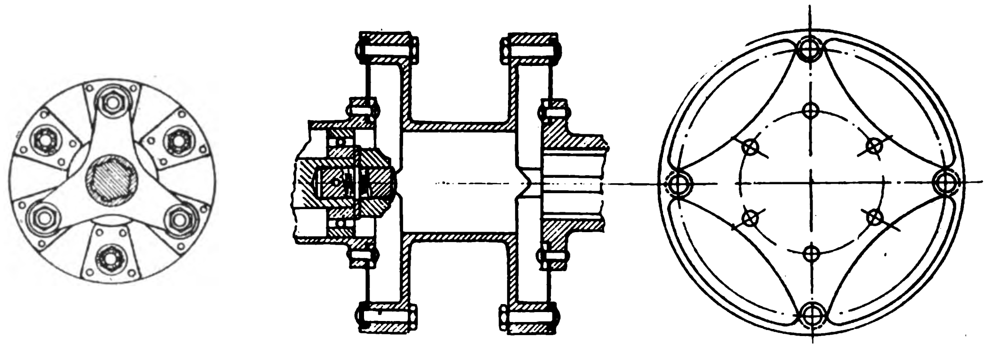

Lubrication of universal joints *Fig.* 10

of any considered scheme for the lubrication of such connections. It may, of course, be argued that leather, fabric, or flexible metal joints may be used for this purpose, and Figs. 9 and 10 show those in most common use, but on account of their diameter and weight, for any reasonable torque, they render gear changing difficult, and, with high-speed engines, are apt to cause vibration on account of lack of balance, which increases with their age. In fact, so poor an opinion has the author of this kind of joint that, although he is the inventor of one of the best-known forms of it, he does not advocate its use.

Gear Box.—It is astonishing that the crude method of lubricating the gear box by filling it with a mixture of grease and oil has persisted so long. To the author's mind, this method should be classed with what an eminent member of this Institution has cleverly called "the unmechanical legacies of our designer-forefathers." The result of this scheme is an immense loss of power and sometimes of lubricant as well. Piles of grease can often be seen in the undershield or surrounding the gear box of many cars after a few hundred miles' running, not always due to design or workmanship, but simply because the over-zealous owner-driver has been too liberal in refilling the box, with the result that the lubricant has been literally forced out by the churning action of the gear wheels inside the casing, which in many cases embraces the gears and other mechanism generally far too closely. In these cases it can safely be assumed that the efficiency losses are even more serious than if the casing was filled only with its proper quantity.

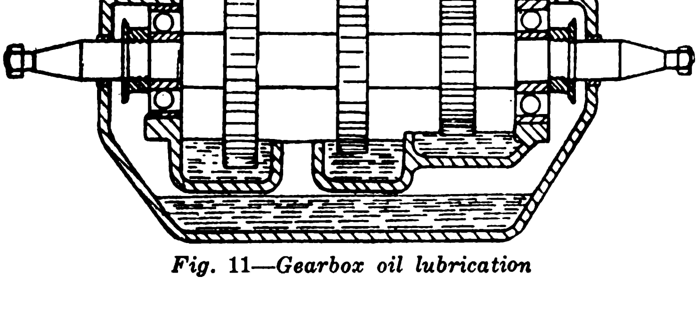

Fig. 11—*Gearbox oil lubrication*

A test of the 32 hp. "Leyland" gear-box was undertaken by the National Physical Laboratory (Report N.P.L., 1914-15, pp. 99-100), which gives the efficiency of the direct drive as being only 74 per cent when the box was full of oil, while, when a quarter full, the value was 97.5 per cent. It is evident that, had grease been the lubricant, the efficiency would have been lower still.

It is to be regretted that no tests with this gear-box were made with any other than the direct gear. Further figures as to efficiency on the different gears would be appreciated should any members have any data on the matter.

A method of oiling the wheels of a gear-box by making each dip into a trough in which oil is maintained at a constant level by a pump is illustrated in Fig. 11.

It has always been the author's practice to put only sufficient oil into the gear-boxes of racing cars that the teeth of the largest wheel alone would dip, but the best method would appear to be to cause a jet of oil to play upon the intersection of the gears on the side of engagement, as shown in Fig. 12. It will be noted that, in this design, white metal bearings are fitted for the shafts, and they are oiled under pressure: it is the author's experience that these are preferable to ball or roller bearings, making, as they do, a quieter and sweeter-running gear-box, without diminishing efficiency. In any case, it seems an unnecessary refinement to fit ball bearings to a device which, as usually lubricated, is more fitted for determining the mechanical equivalent of heat than anything else.

It will be seen on again examining Fig. 12 that this system, like the engine, is self-contained, and the quantity of lubricant is capable of being controlled by a suitable level gage, while at the same time, the pressure feed renders it possible to apply efficient and certain lubrication to the clutch bearing and universal joints on either side of the gear-box, wastage being prevented by gravity return to the sump, and the provision of effective oil retainers.

In those cars in which the engine and gear-box are combined in a single unit, the lubrication of the clutch pilot, gear-box, and universal joint is a more simple matter. In the "Morris-Oxford," for instance, the oil is circulated by the flywheel to the engine on the one hand, and to the gear-box and universal joint on the other. The Fergus car has a pressure system in which an engine-operated gear-wheel pump supplies oil to almost every moving part on the chassis.

It is debatable whether it is better to supply the different

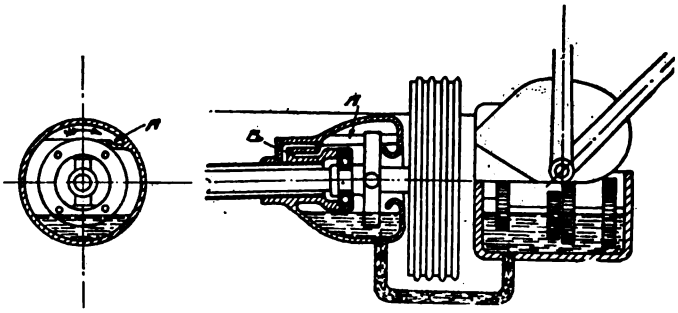

Fig. 17—Means for maintaining oil level in universal

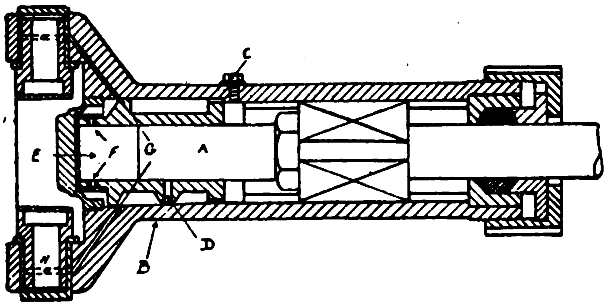

Fig. 18—Oiling universal by plunging action of propeller shaft

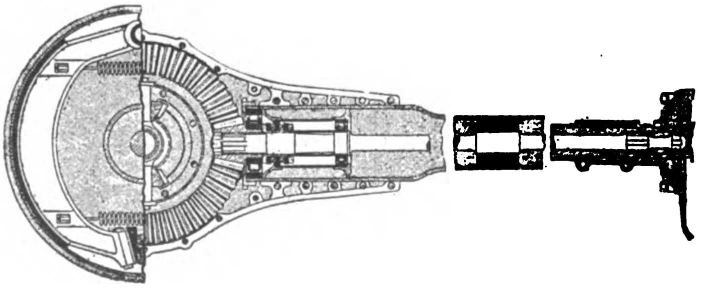

Fig. 19—Fergus rear axle lubrication system

components of the chassis from one source, as just explained, or to arrange a self-contained system of lubrication to each of the important units, as outlined by the author. Although in the latter case the pumps are duplicated, they are simple and nearer their work, and the extensive system of pipes and jointing necessary for the former scheme is avoided, thereby decreasing the risk of leakage and rattle through loose or broken pipe junctions.

Universal Joints—Where universal joints of the Hooke's type are employed, the author finds that their bearing surfaces are commonly loaded to pressures exceeding in some cases 3000 lb. per sq. in. Yet it has been thought sufficient to lubricate them by putting them into an articulated spherical housing in the best examples, or, in the worst, a part-metal and part-leather covering, and filling the casing with grease (see Figs. 13 and 14). The net result is that, when some of the lubricant has worked its way out of the casing, as it invariably does, centrifugal action takes place and the bearings soon run dry. On account of this action, it is essential that Hooke's type universal joints be lubricated from the inside. Fig. 15 shows a method which is favored by the author. In this scheme, oil is supplied under pressure to the center of each flexible joint by a suitable tube or jet. The oil issues from this and is caught by the hollow centre of the trunnion or star-piece. Holes are drilled from the centre to a point near the mouth of the bearing in each pin, and the bush is suitably grooved, so that, as long as the jet is delivering oil, centrifugal force will convey it to all bearings. The outer ends of the bushes are left open to allow of the used oil being thrown on to the casing, from whence it is returned to the sump by gravity.

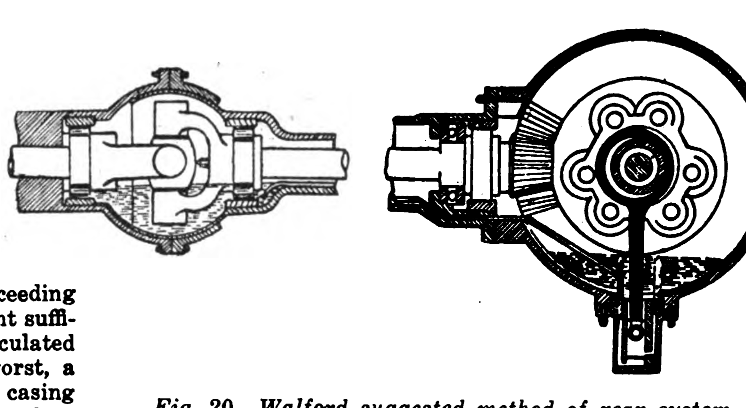

Fig. 20—Walford suggested method of rear system lubrication

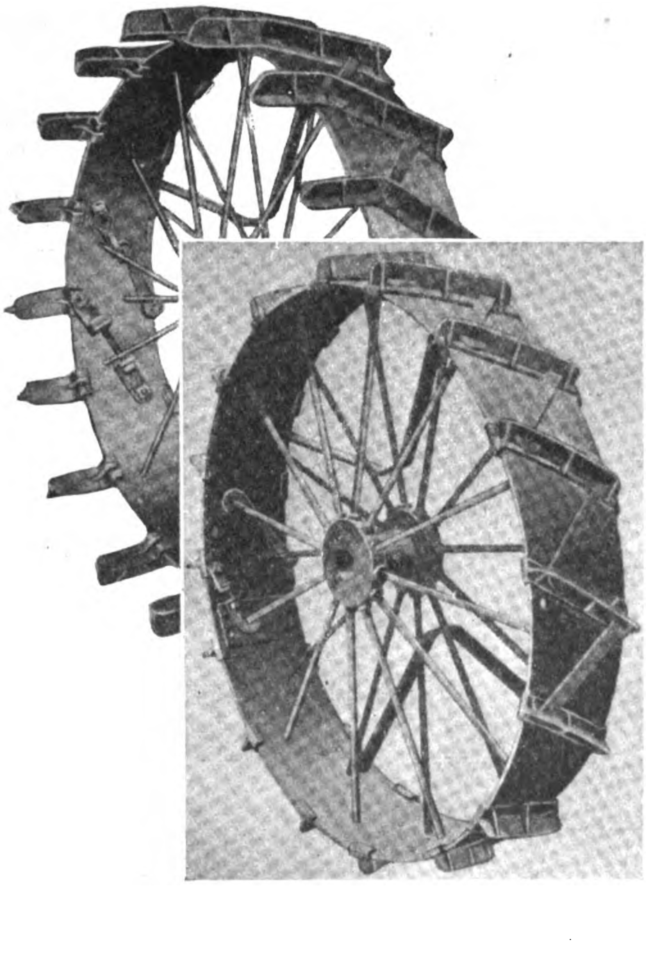
Fig. 16 illustrates a scheme where the joint revolves in a stationary casing. It will be seen that the arms of the star-piece are hollow, and are fitted with scoops which dip into the oil contained in the casing as they revolve. The oil level is maintained by a pump, or by such a device as is illustrated in Fig. 17; Fig. 18 depicts an ingenious method of oiling the universal joint by the plunging action of the propeller shaft.

Propeller Shaft and Torque Tube—The oiling for the front bearing of the propeller shaft and the torque tube is susceptible of varieties of treatment. Fig. 19 represents that adopted in the "Fergus." Fig. 15 is a design of the author's, while Fig. 20 was suggested in an article by Capt. E. W. Walford in *The Autocar*. *(To be continued)*

Loxon Lugs for Tractors



PRACTICALLY all lugs which have been used on tractor wheels so far require bolting to the wheel rim. This is a tedious operation, and rather than spend the time necessary to remove the lugs, the farmer is apt to leave them on whether they are needed or not. When the tractor is doing only light work it is much better to run without the lugs, as the use of the latter always entails some loss of power. For driving on improved roads the lugs must be removed.

A design of quick detachable lug has recently been placed on the market by the Universal Lug Co., Cicero, Ill. There are two principal kinds of parts, the lugs proper, and links. The lug is made in T form, in various heights and sizes. On both ends of each lug is a hook or clamp which fits the thickness of the rim. The key lug, which is placed on the rim first, has a swivel arm attached to one of its rim hooks, this arm fitting into the eye of the rim keeper. After one lug has been placed on the rim, a link is inserted, then another lug is put on, then another link, and so on. The lock lug has a small bracket fastened to one of its rim hooks, with a hole bored through it for a bolt. A rim bracket is permanently secured to the inside of the rim and the locking bolt is then inserted in the lug bracket and the rim bracket, and its nut is drawn up.

It will be seen that the lugs extend across the rim at an angle. Different spacings are used, from 9 to 12 in., according to the size of lug, etc. The general form of the lugs is T shaped, and a number of ribs stiffen the web of the T. Both the ordinary lugs, extending only across the rim, and extension lugs are furnished. While the major portion of the lugs extends across the rim at an angle of 45 deg., the extension part extends parallel to the wheel rim.

Loxon lugs are made in malleable iron, and it is claimed that they can be put on and removed in 5 minutes.

Factors in High-Speed Engine Development

Solution of Carburetion Problems—Making Thermal Efficiency and Horsepower Tests on the Road

By D. McCall White

(Part I—*Continued*)

IT is highly important that when engines are turning fast that the maximum stiffness should be obtained in the cylinders, connecting rods, crankshafts, and above all the crankcase should be extremely stiff and rigid in order to prevent weaving, bearings going out of line, etc., and thus causing vibration and other evils. Fig. 12 illustrates the Cadillac crankcase and method of webbing up for maximum rigidity.

Carburetion Problems

Carburetion is a difficult subject, difficult because of the quality of gasoline, which is becoming worse day by day. As the public becomes more critical of the performance of an automobile, the difficulties presented to the engineer become more acute. Undoubtedly, more heat must be applied to the manifolds to get proper and satisfactory carburetion, assuming that distribution is correct. We keep our manifold temperature around 170 deg. F. by means of thermostatic control, the thermostats being located in the water pumps, causing valves to close or open as the ease may be, thus preventing circulation of water through the radiator should the temperature be low. This has been very satisfactory indeed, but with poor grades of gasoline, more than this has to be developed. Much has been talked about exhaust heated manifolds, but this requires extensive study, as too much heat is as bad as too little and it is possible to lose great power at the higher engine speeds unless great care is taken.

An interesting development is shown in Fig. 13, the illustration being the design for a cylinder having exhaust cast integrally with the cylinder block, completely surrounded with water except the wall next the intake manifold, same being located above the exhaust manifold, the idea being that as the gasses whirled, the heavier molecules were thrown against the intake manifold walls, and, falling to the bottom wall, were immediately volatilized by the heat from the exhaust impinging thereon, the remainder of the gases being at normal water jacket temperature. I designed this engine in 1915 and it was extremely successful, although was never put into production on account of increased radiator capacity being necessary. This layout savors a little as the forerunner of the much advertised hot spot manifold.

Many other devices are in use, such as combined intake and exhaust manifolds, but many of these are, in my opinion, merely an excuse to try to get rid of bad distribution, which is so prevalent, unfortunately, in many of our engines to-day.

The shuttered radiator is also quite a satisfactory layout, but requires considerable development yet owing to danger of freezing shutters shut, wind pressure causing shutters either to remain full open or shut, rattles, etc.

In the Cadillac four-cylinder 1914 type engine, there was used in the carbureter an electric heating element, Fig. 14, consisting of nichrome ribbon between mica sheets, which was attached to the upper surface of the diaphragm, that is, the plate which supports the venturi tube. The gasoline which condensed in the intake pipe and mixing chamber dropped down on to this diaphragm and was vaporized by the heater. In operation, current was put through the heater for a short time before starting, so that this diaphragm and the metal of the venturi tube were heated and any fuel on the diaphragm was vaporized. Fig. 14 shows general assembly of this device.

Horsepower on the Road

The need has often been felt for some instrument to measure the road resistance and horsepower, and a very interesting instrument was developed some years ago in England and has been used by my company since the advent of the eight-cylinder car for this purpose. Fig. 15 shows this instrument, known as the Wimperis accelerometer. It can be used to measure:

1—The road resistance of different kinds of roads or tracks, under various weather conditions.

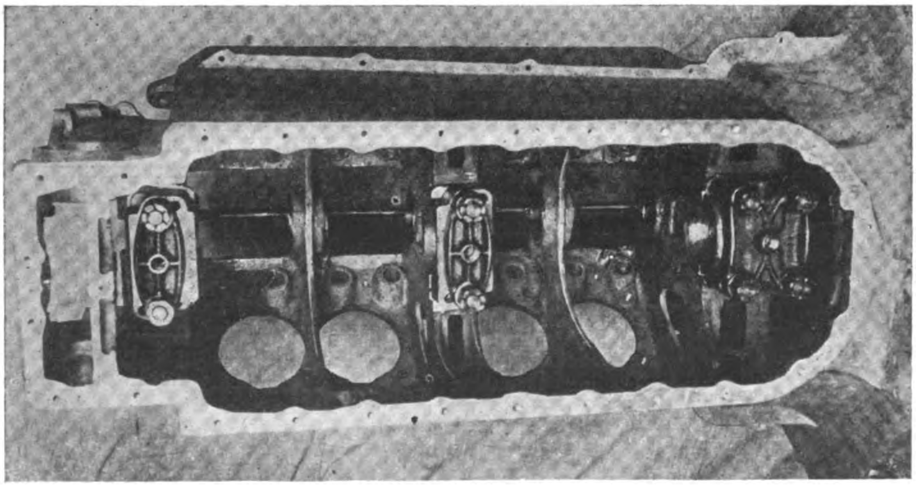


Fig. 12—Construction of the Cadillac crankcase, illustrating the method of webbing up for maximum rigidity

Fig. 15—Wimperis accelerometer used in making acceleration tests

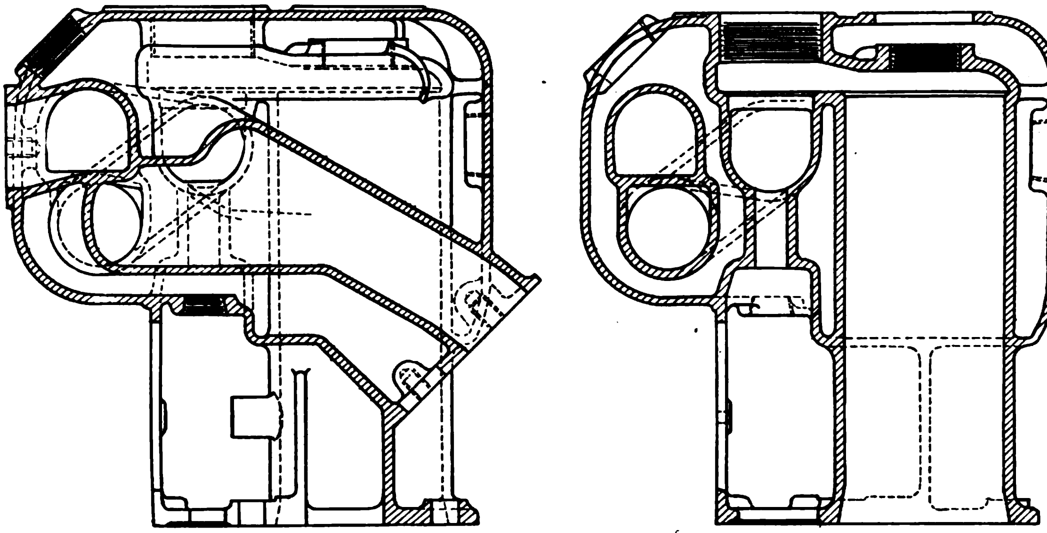

Fig. 13—Design of cylinder having exhaust cast integrally with the cylinder block

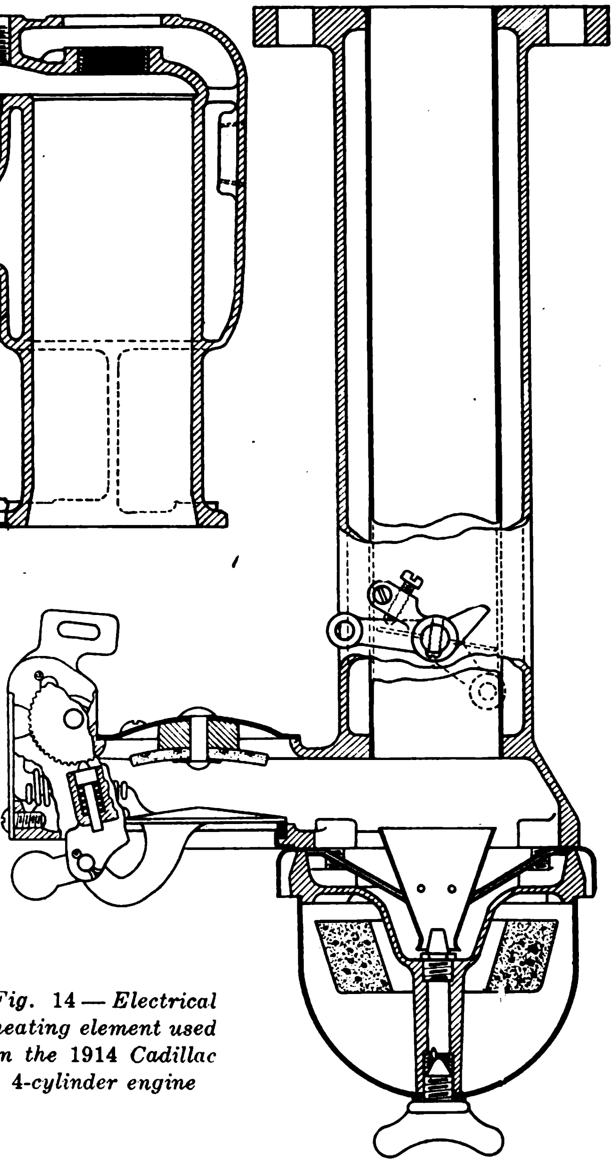

Fig. 14 — Electrical heating element used in the 1914 Cadillac 4-cylinder engine

2—The amount of air resistance due to various forms of vehicles.

3—The mechanical and thermal efficiency of the engine at various speeds under real working conditions.

4—The brake horsepower exerted by the engine when running at various speeds on the road.

5—It is possible to trace step by step losses of power in transmission.

Since the advent of aircraft engines much has been learned regarding weight reduction. I am doubtful if many of the materials used in aircraft engines will ever be used in automobiles, for commercial production, but we have aluminum engines before us and there does not seem to be much doubt but what, perhaps in time, we will see many of these on the road and that possibly automobile engines will come down around 4 or 5 lb. weight per horsepower. We used to dream of 7 and 8 lb. with the accessories and I am in great hopes of seeing good development in this line.

In 1909 I designed a high-speed, four-cylinder engine weighing without flywheel 5¼ lb. per brake horsepower. The 2½ litre Crossley engine weighed 8¾ lb., neglecting flywheel, whilst the 3-litre Vauxhall in similar condition weighed 7¼ lb. per brake horsepower and the Prince Henry Vauxhall 5 lb., whilst the standard Cadillac eight-cylinder engine complete with generator but without flywheel weighs 8 lb. per brake horsepower.

Application of High-Speed Engines to War Uses

Part II

LAST week the general fundamental factor entering into problems of high speed engine design were analyzed and in Part II, this week, a few examples are given of the use to which the high speed Cadillac 8-cylinder engine was put during the war. The following illustrations are of war apparatus using this engine.

Fig. 16 shows a searchlight outfit developed by the General Electric Co. through its engineer, Henry S. Baldwin, working in conjunction with my company, to whom I am indebted for the pictures. A generator having sufficient capacity to operate a 60-in. searchlight for war purposes was mounted on the chassis.

We believe that this is the largest lamp that has been produced, and the car has been thoroughly tested both in this country and for about 6 weeks in France prior to the signing of the armistice. We have records before us that it is a fact that it has never failed to meet any demands upon it as to power and structural features, and taking it all in all, it is

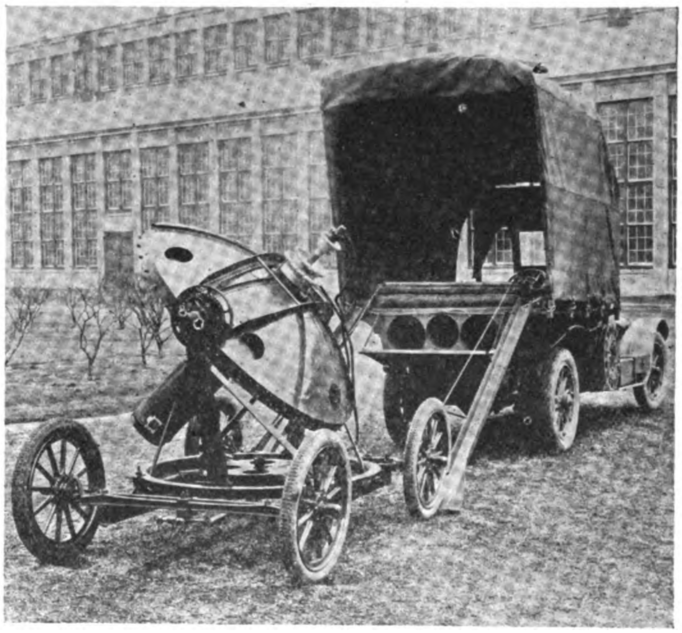

Fig. 16—Searchlight outfit developed by General Electric Co. It has a speed of 45 to 50 m.p.h.

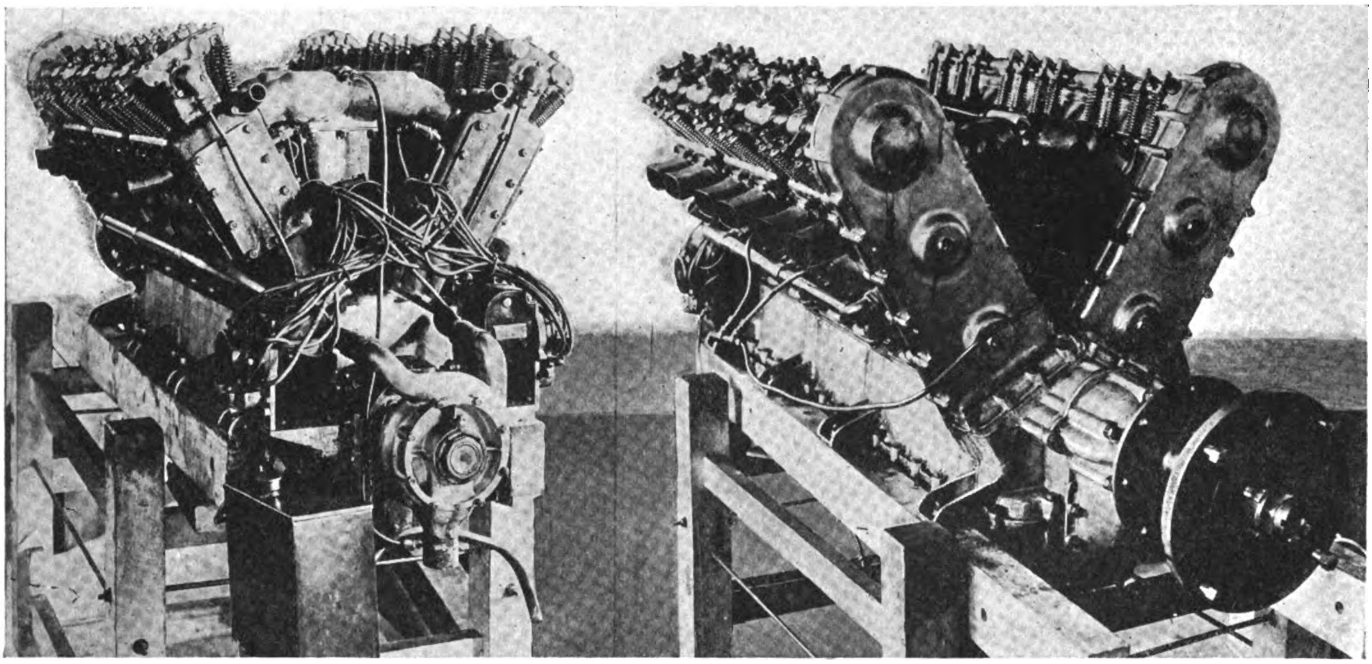

Figs. 19 and 20—Twelve-cylinder high-speed aircraft engine designed by the author in 1915. The bore and stroke are 4 3/16 x 6, and it has twin exhausts and intakes for each cylinder and three carbureters mounted in the center

probably one of the most ingenious and successful devices which have been turned out, weighing about 11,000 lb. less than the outfit which was previously used for the same purposes and having a speed of 45 to 50 m.p.h. against a former speed of 15 to 20 m.p.h.

Another example of the use of the high-speed engine is in connection with tractors. Fig. 17 is a drawing of the 2½ ton U. S. A. artillery tractor, into which was fitted the Cadillac eight-cylinder engine. This tractor was capable, at a maximum burst, of traveling at the rate of 21 m.p.h., which is an engine speed of 3500 r.p.m. Its normal speed is around 12 m.p.h., the engine speed on high gear being 2000 r.p.m., the gears at these revolutions being as follows: First speed, 3.86 m.p.h., and second speed, 7 m.p.h.

The gear rations are as follows, the total reduction being between the engine and the track drive sprockets:

Direct, or high speed	13.01 to 1
Intermediate, or second speed	22.25 to 1
Low, or first speed	40.50 to 1
Reverse	48.65 to 1

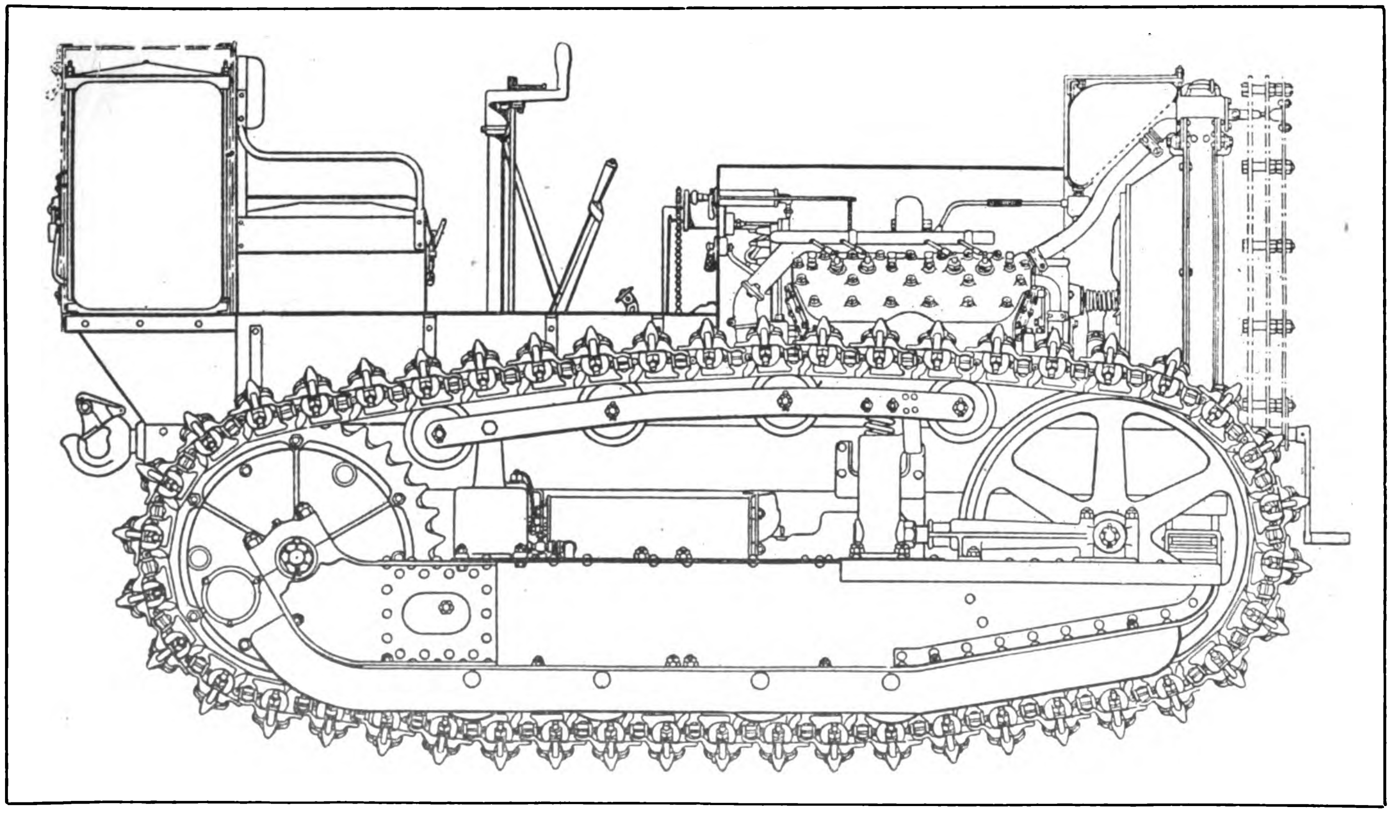

Fig. 17—Application of a Cadillac 8-cylinder engine to a 2½-ton U. S. A. artillery tractor. The normal speed of the tractor is 12 m.p.h., but it was capable at a maximum burst of 21 m.p.h.

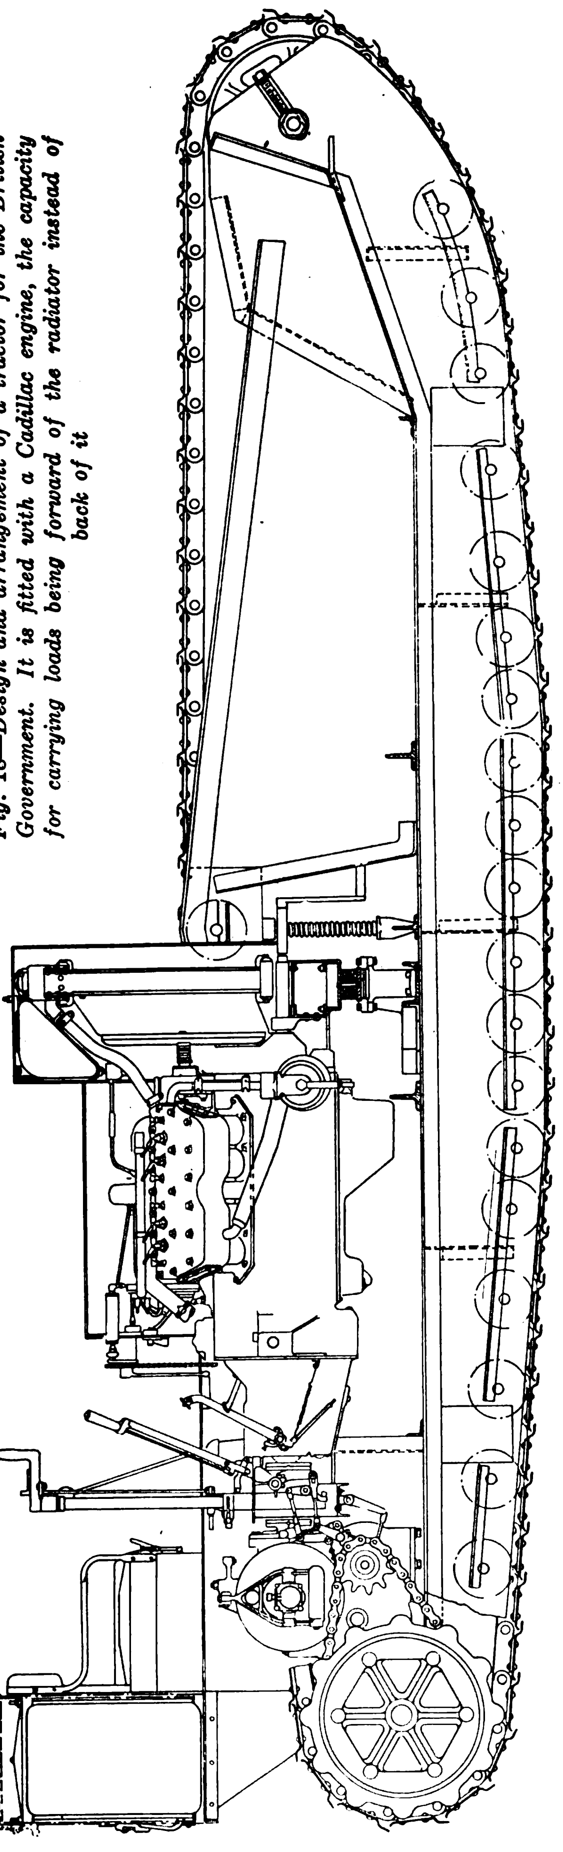

Fig. 18—Design and arrangement of a tractor for the British Government. It is fitted with a Cadillac engine, the capacity for carrying loads being forward of the radiator instead of back of it

Fig. 18 shows a layout of the Cadillac engine fitted to a tractor for the British Government, its capacity for carrying loads being forward of the radiator instead of behind it as was the case in the 2½-ton U. S. A. tractor.

Figs. 19 and 20 show a high-speed aircraft engine designed by myself in 1915. This engine had twelve cylinders, 4 3/16 by 6, having two exhausts and two intakes per cylinder, three carbureters mounted in the center, and owing to inability to obtain battery ignition, the engine was tested out with two twelve-cylinder magnetos. The design had a dry crankcase so far as oil was concerned, having two oil pumps with a cooling system and geared-down propeller, as the engine was designed to pull 350 horsepower at 2400 r.p.m.

The weight with cast iron cylinders was 1000 lb., which of course amounts to 3⅓ lb. per horsepower, which weight could, with steel cylinders, have been very considerably reduced.

Chromium Steel for Permanent Magnets

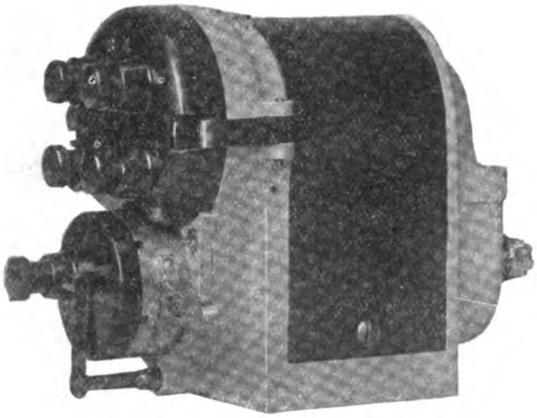
A GOOD deal of research work on magnet steels has been conducted at the Reichsanstalt during the war; only part of it has, so far, been published in the *Wissenschaftliche Abhandlungen.* One of the points investigated is the substitution of chromium steel for tungsten steel. Bar magnets of chromium steel, stored for a year without being exposed to any disturbance, kept their magnetic moment constant within 0.3 per cent and less; in all the cases the changes observed were within the limits of the experimental error in the second half of the year. As regards constancy to heat variations and concussions and temperature coefficient the chromium steel proved equal to tungsten steel; in coercive force and remanence the best chromium steel did not come up to the best tungsten steel. The temperature coefficient of the magnetic moment diminishes with increasing content of dissolved carbon and was found to be zero in a 1.4 per cent carbon steel. To investigate the suitable ratio of length to diameter in the case of bar magnets a chromium steel originally 22 cm. in length and 0.6 cm. in diameter was gradually shortened to a length of 2.4 cm.: this shortening raised the temperature coefficient from 2.4 per cent up to 4.2 per cent. The ratio of length to diameter l/d was also found not to be without influence on magnetometer determination of the coercive force. When the value of l/d fell below 10, these determinations gave too low values; practically this point is not important.

Benzol as a Motor Fuel

NOW that war demands have ceased, says the *American Gas Engineering Journal,* the producers of benzol are hoping to put a large proportion of their output on the market as motor fuel. The defects of benzol for that use, which defects need no longer exist, are of four kinds: (1) The valves and valve-stems of the engine become coated with a gummy substance which causes them to stick in the guides; (2) the valve faces become in time deeply corroded and pitted; (3) in cold weather the benzol may become frozen, and (4) the benzol contains water, which collects in drops, and finds its way into the carbureter, where it prevents a free flow of the fuel to the jet. The causes of these troublesome circumstances are now well known to benzol producers, and they may be easily removed. The gummy deposit is due to insufficient washing with strong sulphuric acid. Pitting of the valve-seats results from using benzol which contains an excessive amount of sulphur. Freezing is due to the presence of too high a proportion of benzine. Water is usually found in benzol which has not been sufficiently matured. The water, always present in the distillate, takes some time to settle out. The benzol should therefore be left to stand several days in the storage tank before being transferred to drums. To run off the water, all storage tanks should be fitted with drain-cocks at their lowest point. Attention to these matters will insure a good motor fuel. When filling drums and tins, all benzol should be run through a fine gauze. It has been proved that bulk for bulk benzol gives more power, and therefore greater mileage than gasoline.

Kliesrath Magnetos

Made in 1, 2, 4 and 6-Cylinder Models by the Simms Magneto Co.—Of Water-Proof Construction and Provided with High Speed Interrupters



Kliesrath model K-4 magneto. Base and end plates are a single casting

THE Simms Magneto Co., East Orange, N. J., is continuing some of its earlier models, the 4 and 6 cylinder open type, and in addition has recently brought out several new models, from designs by V. W. Kliesrath, who for many years was chief engineer of the Bosch Magneto Co. When Mr. Kliesrath joined the Simms company, the first work he did was to design 4 and 6 cylinder water-proof models, known as models K-4 and K-6, which have end plates conforming to the shape of the horse-shoe magnets, with grooves running around the edges which are packed with felt soaked in grease. Another improvement introduced by Kliesrath was to provide the interrupter with a rubber bumper to make its operation at high speed more nearly positive. The interrupter arm is held against the cam by a spring, and at high speed, when the cam strikes the arm a severe blow, there is a tendency for the arm to be thrown from the cam, and for contact between the points to become unreliable. The rubber bumper limits the distance the points can separate, and, therefore, enables the interrupter to work reliably at higher speeds.

Mr. Kliesrath also developed 8, 12 and 16 cylinder aircraft magnetos, all structural parts of which are made of aluminum. Tie rods are used for holding the end plates to the magnets, this construction being more secure than the use of screws. Small single cylinder and two cylinder magnetos have also been developed for use on stationary, marine and tractor engines.

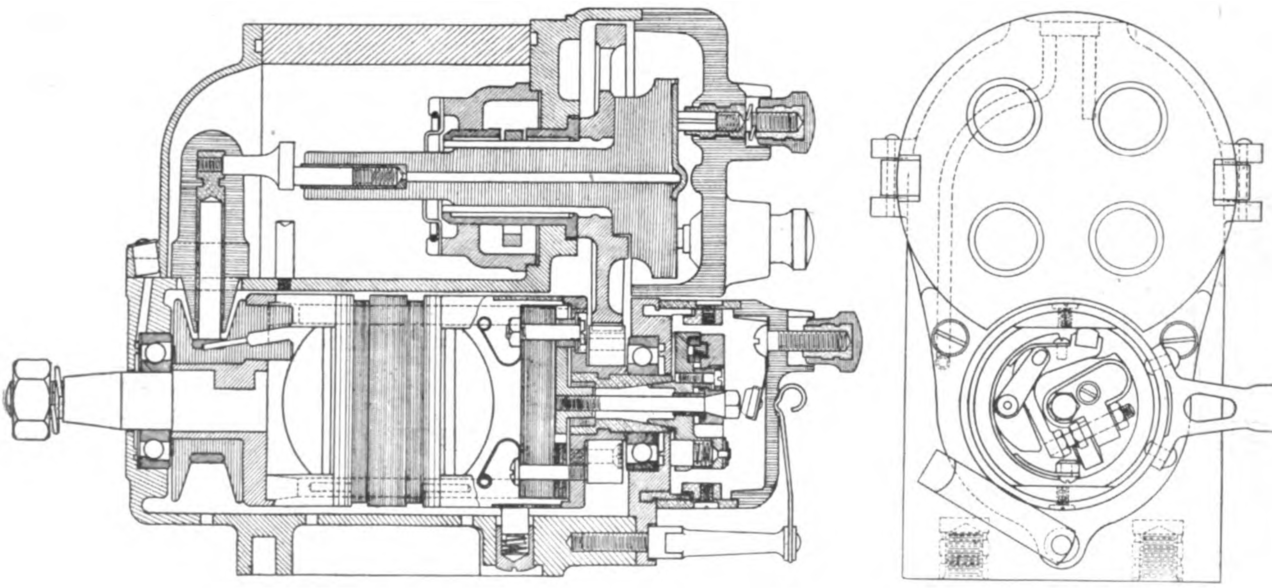
The new Kliesrath 4 and 6 cylinder types have straight lines, and are of compact design. They have been designed throughout with a view of allowing manufacture of a high-grade instrument, at less cost than has been possible heretofore. Special attention has been given to a proper balance between the amount of magnetic and conducting material in the armature, the object being to obtain greater output from an instrument of a given weight. The distributer gear is made from a material manufactured by a new process, and meshes with a composition noiseless gear on the armature shaft. This material has a great tensile strength, and is particularly adapted to withstand the abuse which is unavoidable with an impulse starter. Large Norma ball bearings are used at both ends of the armature, while the distributer shaft is mounted in a plain bearing, lined with frictionless metal. The gear teeth are so designed as to withstand the excess load due to the recoil on the impulse starter. The characteristics of this instrument are such as to make it possible to obtain a full strength spark at 34 r.p.m. with the timing lever set in the most advantageous position, and at 85 r.p.m. when set at full retard. An ample timing range (35 deg.) is provided.

The Simms company also has recently placed on the market an automatic impulse starter, the main feature of which is that it goes into the same space ordinarily occupied by the magneto coupling. This enables manufacturers to provide for an impulse starter without making a change in their designs. This starter is fully automatic and requires no attention from the operator. It is completely protected from dust, and does not have to be oiled. The design is such that it can be said to cut in and out automatically, at any speed desired, by the manufacturer. It is self-contained, and is mounted as a unit on any standard type of Simms magneto.

—

Editor AUTOMOTIVE INDUSTRIES—I note that the tables of airplane radiator performance, from my paper on this subject, which were reprinted in the March 13 issue of AUTOMOTIVE INDUSTRIES have been copied from the advance copy of the paper gotten out by the S. A. E.

As the printers of this advance copy added two and three zeros to my original figures I would appreciate it if you would insert a small note in some coming issue to warn designers that the accuracy is not carried to the extent implied by some of the figures.—ARCHIBALD BLACK.



Cross section and end view of Kliesrath 4-cylinder magneto

F-5-L Navy Flying Boat

Details of the Hull Construction—Design and Materials of Various Fittings—Panel and Strut Layout

By S. T. Williams
Assistant Chief Engineer, Naval Aircraft Factory, Philadelphia

Part II

IN the previous issue the general description, construction and performance of the model F-5-L Navy flying boat was described. It was shown, briefly, to be a twin Liberty motored biplane, having a wing span of approximately 104 ft., mounted on a hull or boat, permitting it to ascend or light upon the water. The general features of the plane were mentioned—namely, the fine streamline form of the hull, design permitting speedy production under war conditions, and the extensive use of veneer and laminated construction. The major details of this construction exclusive of the powerplant and controls will now be described.

Considering first the hull, either of two general statements are true—it may be termed a speed boat to which wings are attached, or it may be described as a standard airplane fuselage to which a V-bottomed substructure has been added in the place of the land plane's undercarriage and wheels. In either case, it serves the dual duty of carrying the crew, gasoline, etc., and as a landing device.

Hull Has Planked V-Bottom

The hull is built up around four longerons, as is a land plane, and has in addition a keel and a planked V-bottom that is flared out to present more landing surface. The flared out portions are called fins, and in this plane are an integral part of the hull structure, and are continued aft, and streamline into the hull sides. This is not the case in many previous seaplanes, namely, the H-12 and the HS-1 and 2, where the fins are stopped abruptly about one-third the hull length aft from the bow, and the advantage is increased strength and better streamline form.

Before entering into a detailed description of the hull construction, it may be well to define some of the terms used. The following defines them roughly and is the order in which they enter into the hull construction:

Keelson—A wide thin plank extending from near the bow to the stern, above the keel.

Keel—The bottom-most longitudinal member forming the backbone of the hull.

Floor Frames—The transverse planks jointed at right angles to the keelson.

Longerons—All longitudinal members extending from the bow to the stern with the exception of the keel.

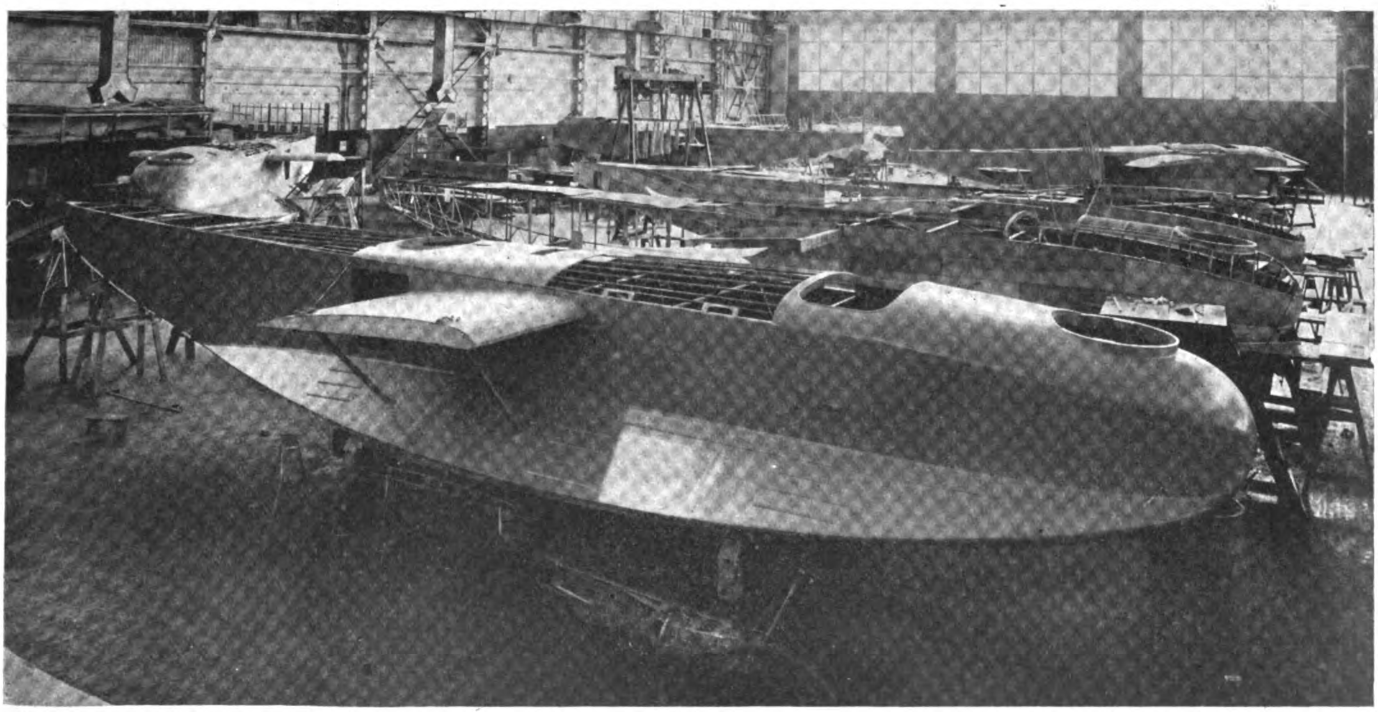
Fin Edges—The two outside longitudinals of the fins.

Stringers—The longitudinal strips connecting the floor frames on the bottom and the strips on the fins.

Bulkheads—All transverse veneer structures dividing the hull framing.

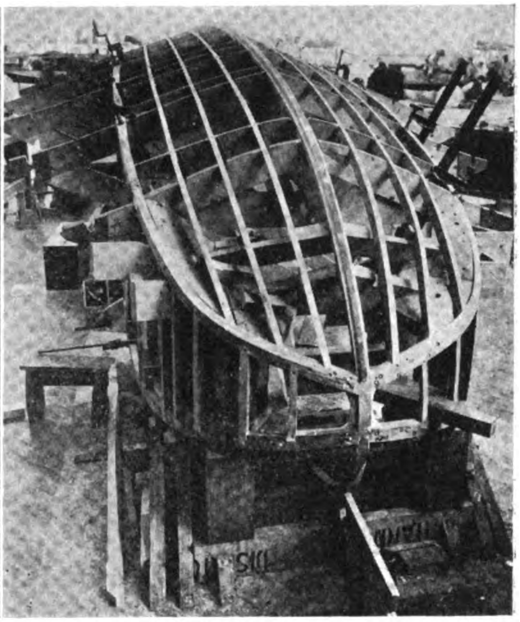
Transverse Bracing—The central structure connecting the hull to the two wing beams extending through the hull.

The keelsons are ½ in. basswood, built in not more than 5 sections, having at least a 9 in. scarf at the joints and held together with copper rivets. To this the floor frames, also ½ in. basswood, are notched and securely riveted by two corner stringers. Throughout it will be noted that built up members are used, permitting the use of readily available material.

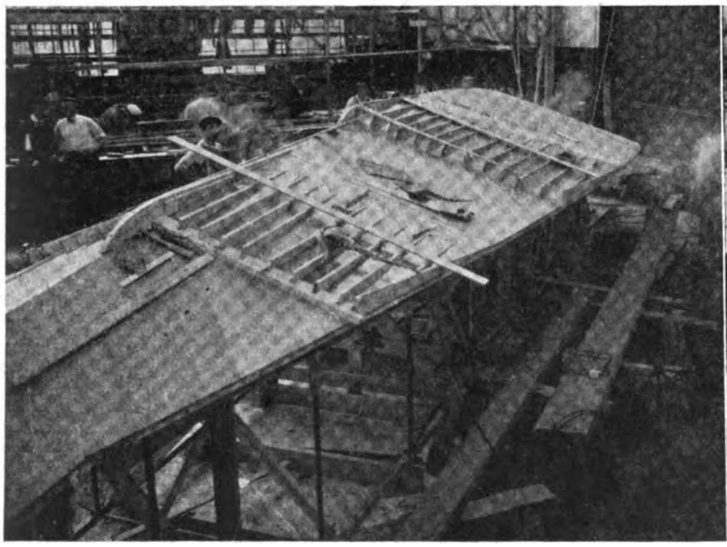


Complete hull assembly for the F-5-L Navy flying boat. This is a twin Liberty-engined tractor biplane and the hull measures 45 ft. in length and 10 ft. wide. The total flying weight of the boat is 7 tons

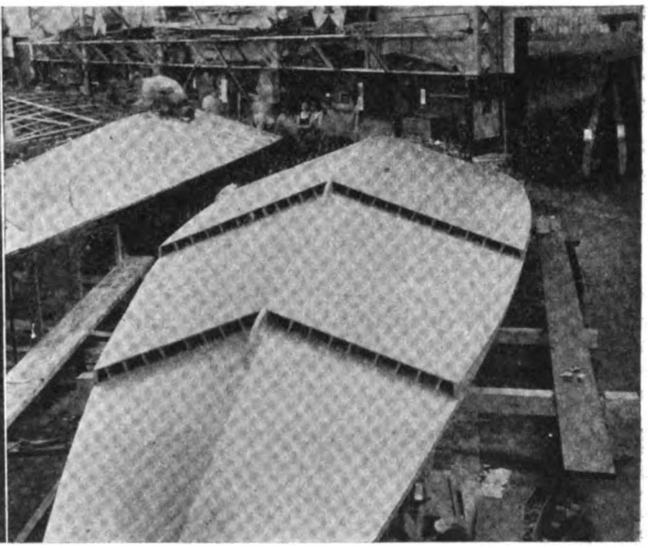
Building up the hull of the F-5-L flying boat, showing the frames in places ready for keel and stringers



Front view of the boat hull frame somewhat further along in construction



Three-quarter aft side view of the under side of the hull, showing the method of building up the steps



The hull bottom completed, showing the two steps, their location and depth as compared with the width

White ash is used for keel, longerons, fin edges, and the bent ends of the stringers. These two may be built up or spliced, but not more than four sections may be used. The scarfs in the keel must be at least 18 in. long, and are copper riveted. Formerly a straight scarf was used, as it was considered a better production proposition, but now a stepped scarf is used, as it was found that the time saved in making the straight scarf was lost in assembly.

Similar methods of splicing are used in the case of the longerons, fin edges and stringers, and here the joints are served and doped. Care is taken in the location of all splices in longitudinal members, so that a number of splices will not occur in any one section, causing a weak section and failure. For example, not more than two longeron splices may appear in any one bay, and these must both appear in either the upper pair—to balance each other.

By this method of splicing ash longitudinals, and the careful location of joints, short lengths of ash can be used. And this is important, as airplane ash under any condition is not easy to secure.

All ash members are steam bent to assembly shape before assembly on the hull forms. This bending and the splicing of the complete longitudinals are done in a separate part of the shops. Likewise the keelsons and floor frames, stringers, bulkheads, posts, struts, braces, etc., are sub-assembled, and when delivered to the hull erection floor are ready for assembly but with little fitting. This idea is carried out even to the bottom planking, which is delivered in amounts sufficient for one hull. But a detailed description of this subassembly construction is too involved for comment here.

Throughout the hull construction all parts are tied together by metal fittings—and concerning these metal fittings three points are noteworthy as aiding increased production. The first is a choice of material used. One generally considers the steel entering into airplane construction as being the best possible, and heat treated to the greatest strength. But fittings on this plane are in general soft or mild carbon steel.

The reasons for this are that such steel can be procured almost anywhere, is easily worked and welded—and loses little of its strength through abuse in brazing, welding or forming. Its analysis (sheet steel only) follows:

Number	Carbon	Manganese	Phosphorous	Sulphur
1020	.15.... .25	.30.... .60	.045 max.	.050 max.
1025	.20.... .30	.50.... .80	.045 max.	.050 max.

The second point to be noted in the fittings is that, with few exceptions, they are built up from flat patterns bent and brazed or welded. This eliminates drop forgings, which were

so difficult to secure, and permitted production to go ahead without waiting on the construction of dies.

In fact many planes were built before it was possible to get dies made for punching out the flat patterns—these being sawed, ground, profiled and finish-filed to shape by hand. Hand labor was expensive, but waiting on equipment was more so, and the construction of the fittings is such that hand labor was placed to the best advantage.

The third feature of the fittings is the use of identical fittings in many places. For example, throughout the hull, the junction of the posts and the longerons; the point of attachment of the floor frames to the longerons, and the plates covering the joints of the hull bracing—fittings differed only slightly at the different stations.

However, originally each similar fitting differed slightly, necessitating a separate template, a separate print, part number, operations, etc., throughout the whole construction. But a study was made and an "average fitting" made that would suffice for several similar stations. The fact that such fittings did not exactly fit anywhere, or had lugs that were not needed other places, amounted to less than they saved time in production. And they were structually as good.

Ash Tie Strips Displace Riblets

A further difference in the construction of this hull and that of similar hulls of its predecessors is to be noted. On previous models, riblets were used to connect the keel with the fin edge stringers. These riblets were about ½ x ½ in. ash, spaced at distances varying from 9 to 15 in. transversely across the boat bottom. To bring their bottom surface flush with the stringers, lower longerons and fin edges, it was necessary to notch keel, stringers, longerons and fin edges that they might be set in. And it was a slow tedious job.

On this unit, the riblets are omitted, though several ash tie strips are used to connect the keel with the fin edges. It is considered that these, together with the planking, provide transverse strength in abundance.

Another feature in the construction is the extensive use of steel tubing as struts and posts in the body bracing. This is particularly noticeable in the tail, where the parts are under no great strain, and are not used for the attachment of other parts. Steel tubing is readily procured, and ready for use by simply cutting to length.

The central or transversal bracing unit is a complete unit in itself, and is set up as a separate assembly previous to installation in the hull. This differs from the usual construction and permits the use of templates to assure accuracy.

The transverse bracing connects the hull to the wings and the hull may be said to be built around this unit. By making all transverse bracings identical, any set of F-5-L wings, engine mountings, etc., may be more readily installed.

It is also to be noted that the wing beams passing through the hull are spliced at the center. These beams, styled the sidewalk beams, as they carry a short veneer covered wing section at each side of the hull that is used as a sidewalk for the mechanics to reach the engine, may be removed when the hull is packed for shipment. This permits the use of a much smaller shipping crate, permitting the shipment of more planes, and the use of less material in crate construction.

The bottom planking comprises an inner and an outer skin, each of 7/32 in. cedar. The inner skin is placed at right angles to the keel, differing from usual practice wherein both layers are at an acute angle to the keel. As riblets are eliminated, the right angled inner planking tends to replace them as strength members. This inner planking is either Port Oxford or Spanish cedar in random widths of from 4 to 10 in.

The outer planking is placed at an angle of 45 deg. to the keel, the acute angle being on the aft side. All pieces are from 4 to 5 in. wide, Spanish cedar, and are screwed to all longitudinals. The two layers of planking are secured together by brass clinch nails.

Courtrai, a special fabric, is laid in marine glue between the two layers of planking, and is used extensively in rendering all joints tight. All planking is laid with a slight clearance to allow a go-and-come resulting from moisture changes.

The bottom steps are secured in place after the hull is planked. They are two layers of 7/32 in. mahogany planking, fabric and marine glue between, screwed and clinch nailed together, and secured to the hull bottom by copper rivets, being separated from it by triangular ash strips. The forward ends of these steps is scarfed and set into the hull planking, a thick brass strip being set in flush over the joint.

Veneer is used extensively throughout the balance of the hull covering. This comprises the top fin edge planking, the nose planking, and the side planking. Formerly the side of the hull aft of amidships was covered with linen, taped, doped, and painted, with the exception of a narrow washboard. But in severe service, the linen covering proved too weak, and ⅛ in. 3-ply waterproof veneer is now used.

An extended technical description of the panel, strut and tail construction could be expanded to many volumes. But the outstanding features of these are laminated beams, simple strap type wing and strut fittings and laminated uniform section struts.

At one time laminated or spliced beams were not in favor but the shortage of long spruce necessitated the use of laminated and spliced beams. And it is found that the laminated beam is better than the unlaminated one. Outside of the economy of material, the ease of drying pieces of small cross section and the resulting dependability of built up beams more than offsets any additional expense in manufacturing.

Two types of laminated beams are used—the two-piece and the three-piece. The former is simply two pieces placed back to back, and glued together. The two halves are of equal thickness, and are lightened as was the solid beam except at splice positions. Scarfed splices are used, and staggered in the two halves. The two-piece beam may be used anywhere, and must be used in the following places: All front beams (except engine section), horizontal stabilizer beams, and rear aileron beams.

The three-piece beam comprises a thin piece sandwiched between two thicker outside pieces, glued together, and lightened similar to the solid beam, except at splices. This construction is used in the sidewalk and engine section, or for rear beams. Of the two types, the two-piece is considered stronger, and hence the above distinction of their use.

The idea of using strap fittings and the elimination of forgings and machined fittings extends to the strut and wing fittings. Here also mild carbon steel is used, cut from flat patterns and bent to shape.

Details of the Fittings

The base wing fitting is a U-strap, bent around and bolted to the beam. From it lugs are bent for interwing wiring, and the interplane side has a cloverleaf extension for the attachment of the struts and wire terminals. These are reinforced by washer plates to provide bearing for the bolts.

Roughly, the beams are secured to the strut ends by a bolt passing through the central cloverleaf and the strut end, and the usual strut socket is eliminated. In detail, the strut end is squared down, drilled to mate with the central cloverleaf hole, and a steel tube fitted in the end to give greater bearing and prevent the strut end from being crushed when the throughbolt is tightened.

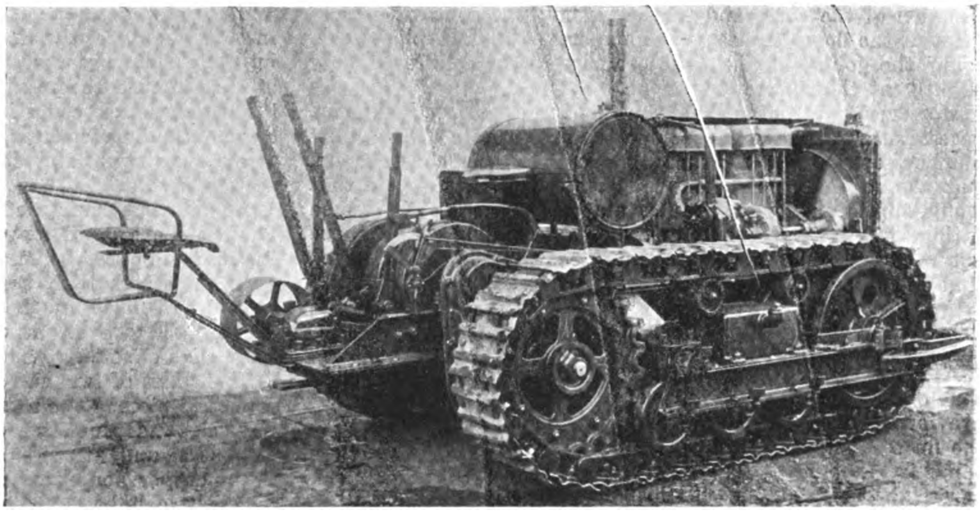
The throughbolt has a standard eye head, permitting the attachment for the drift and anti-drift wires, where a single wire is used. When double drift wires are used, the throughbolts holding the flying and landing wire clevises are made with an eye. Bearing for the strut ends on the beam is secured by means of a thin bearing plate between the strut and the beam.

It was observed that considerable time was lost in shaping the tapered streamline section struts, and furthermore, these being in two-piece construction, required thick material that was difficult to obtain. Hence, a three-piece uniform section strut was chosen.

As stated, this strut is three-piece, and all the lightening is done in the central portion. In the rough it is a flat board, the length and width of the strut, with a series of oval holes cut out of the central portion on a vertical spindle shaper. The cheek pieces are then glued on each side, and the strut rough machine planed to a streamline section. It is then finished to the desired section by hand. *(To be continued)*

Laughlin Husky Tracklayer Type Tractor

Has Low-Speed Engine Delivering 20 Hp. on the Belt—Steered by Applying a Brake to the Driving Mechanism of One Track or the Other



Laughlin tracklayer type tractor, showing steel chain tread

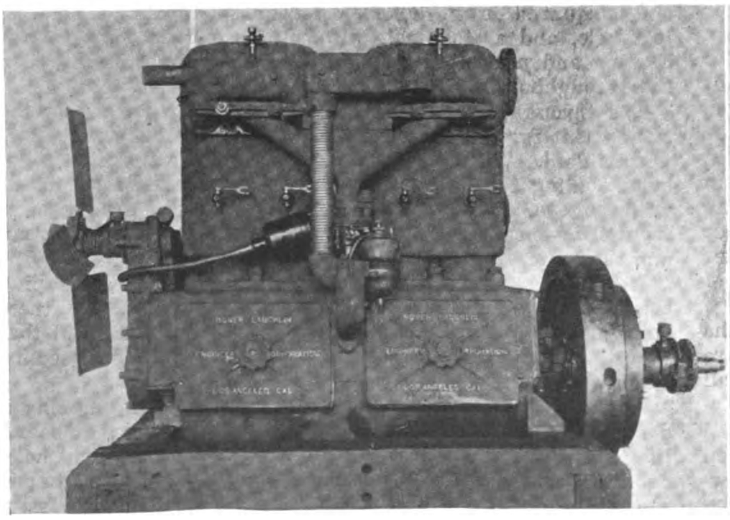
A NEW tractor for farm and orchard work has been placed on the market by the Homer Laughlin Engineers Corp., Los Angeles. It is of the creeper or tracklayer type, and one of its special features is a patented chain tread, which is made from hardened steel claimed to be tough and durable. Ten tractors equipped with this tread have been in use for over three years, and show no appreciable sign of wear, we are informed. The chain has no loose spools or pins, the principle being similar to that of a train coupling. The shoes are made of ¼-in. hot pressed plow steel, 10 in. wide, and are bolted to the track links.

The engine used on this tractor is the Laughlin heavy duty, slow speed design, of 4⅜-in. bore by 5⅛-in. stroke. It is rated to deliver 20 hp. at the belt pulley, operating at a governed speed of 700 r.p.m. The cylinders are cast in pairs, with detachable cylinder heads. The crankcase is a one-piece casting, with removable splash pans.

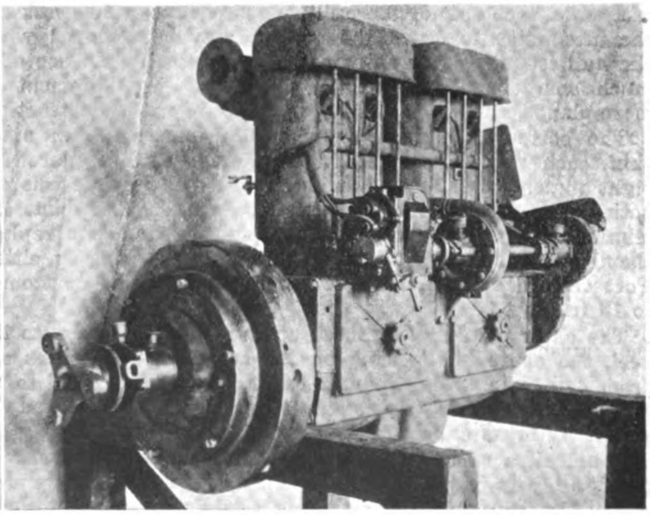
The valves are located in the cylinder head; they are drop forged from nickel steel and have a clear diameter of 2 in. The piston pin is 1 7/16 in. in diameter, hollow, hardened and ground. Its bearings measure 1 7/16 x 2¼ in. The crankshaft is supported in three bearings, of the following dimensions (front to rear): 2½ x 3¼ in., 2¼ x 3¾ in., 2¼ x 4⅞ in. The connecting rod bearings are 2¼ x 3 in.

A governor of the centrifugal type is fitted, and is entirely enclosed. It insures close regulation of engine speed. Ignition is by a Dixie high-tension magneto with impulse starter. Cooling water is circulated by a large centrifugal pump with enclosed driving gears. The radiator is of unusually large surface, and is provided with a positively driven fan.

The transmission is of the sliding gear type, and gives two forward speeds and one reverse, the two forward speeds being 1.7 and 2.7 m.p.h. respectively. All gears



Side view of engine. Note carbureter mounting on crankcase, and flexible inlet pipe



This view of the engine shows the valve rods, magneto and pump

are made of forged steel, hardened, and their shafts are mounted in ball bearings. The gear is fully enclosed and runs in a bath of oil.

Each track of the tractor is operated independently through a friction clutch. The friction clutches are of the expanding segment type and are faced with maple blocks. A clutch brake is applied automatically when the clutch is disengaged. The sprocket rims are cast in chills, which gives them a hard, long wearing surface. These sprocket wheels are demountable. There is one sprocket on each side, and they are driven by large external cut gears, fully enclosed.

The tractor has an independent track frame. The pivoting axle is located just ahead of the track sprocket. It is claimed that this new feature takes all strain off the driving gears. There are three track wheels on each side, these being mounted on Hyatt roller bearings. The track shoes are of pressed steel, 10 in. wide. The tracks have a bearing area of 12,000 sq. in., making the unit pressure 5 lb. per sq. in., as the total weight of the tractor is 6000 lb.

The power take-off pulley is located in the rear in such a way that the belt can be easily tightened.

Searchlight Arrangement on Italian Aircraft

AN article in the *Oesterreichische Flug Zeitschrift* describes the arrangement used on Italian aircraft to illuminate the ground on starting and landing during night flying. Two kinds of power sources are used—first, an accumulator battery, seldom employed because of its high weight for the required capacity, and, secondly, a dynamo, sometimes in conjunction with a battery. The dynamo is either driven by a fan or connected direct to the engine, both having their advantages and disadvantages. The first is independent of the motor, but its efficiency is low. The second is more efficient and is the one that in future will be most employed. In both cases the revolutions per minute are not constant, and therefore the voltage alters, and, accordingly, the dynamo must be fitted with a voltage regulator. The voltage is regulated by increasing or decreasing the current in the shunt winding of the motor. The voltage of the lighting system is usually about 14 volts and current 9.1 amps (125 watts). The energy, loss, etc., in various parts of the system is discussed at some length and the efficiency for a fan-driven motor system given as 125 watts/411 watts $\times 100 = 30.8$ per cent. The weights of the parts in this case are:

Dynamo, together with propeller and support	13.5 kg.
Light reflector and lamps, etc.	6.0 kg.
Controlling apparatus and lead	2.05 kg.
Accumulator	8.0 kg.
Total	29.55 kg.

Measuring Noise Electrically

A METHOD of measuring the intensity of noise, which may prove of use in demonstrating the silent operation of passenger cars is described in *Electrotechnik und Maschinenbau* for Dec. 15. According to the article, it is possible to measure the intensity of a noise by measuring the current in a circuit inductively coupled to a circuit containing a microphone exposed to the sound waves. The measuring instrument may be either an oscillograph or a baretter. Oscillograms produced in this way by an automobile and by an airplane are reproduced in the article. Small differences in the intensity of a noise are best obtained by a baretter in a bridge connection that is suggested. In other cases resonance methods are recommended. The methods should be of use in experiments with the object of reducing the noise produced by airplane engines, says the author. He thinks it should be possible to silence the engines by causing an interference to take place between the waves emitted by the different exhausts.

New Models at Lyons Fair

(*Continued from page* 683)

are carried right out to the frame members, thus avoiding the use of an underpan, and the oil pump, driven off the camshaft can be withdrawn complete with its gears, its shaft, housing and pinion, these forming one unit.

With this general arrangement everything is getatable. There is nothing whatever in front of the valve stems. The magneto contact breaker and distributer are facing outwards. The electric generator and starting motor are slightly above the top of the side frame members and there is nothing to interfere with the accessibility of the carbureters.

A three-stage aluminum crankcase has been adopted; the upper portion, which is bolted to the frame members at four points, receives the cylinder casting, the central portion is a girder construction receiving the bolts for the main bearings, and the lower part is merely an oil pan having a filter along its whole length and receiving the oil pump.

The crankshaft 2 in. in diameter is carried in four plain bearings. It is machined all over, balanced by three counter weights, and is drilled for forced-feed lubrication.

The connecting-rods are I-section machined all over, attached to the crank pins by four bolts each, and to the forged steel pistons by means of a hollow wrist pin, which is locked in the piston bosses in a manner shown in the illustration. There are three compression rings of the stepped type.

The camshaft and accessories are driven by two silent chains.

The design of the exhaust manifold reveals racing experience. This organ is in two parts to allow for uneven expansion; it broadens as it nears the rear and is divided down the center so that the exhaust from the forward cylinders will not meet those of the rear and cause back pressure. The exhaust ports are big and so shaped as to liberate the gases with the least amount of friction. The entire arrangement gives the free release of the gases as effectively as with separate exhaust pipes, while having the advantage of a neat single organ which does not interfere with the accessibility of the valve stems.

Bolted up to the engine base chamber is another housing containing the dry-disk clutch, alternative plates of which are lined with ferodo fabric.

There are four forward speeds and reverse, and the whole of the pedals and control levers are mounted on the gearbox casting independently of the frame.

Delage has always been a partisan of Hotchkiss drive and has maintained it in this model, with of course, a universal joint at each end of the propeller shaft. Rear axle is full floating type, with a wealth of ball bearings both for the driving couple and for the differential shafts. As the drawings show, the driving pinion shaft is carried in double radial and double thrust ball bearings at its forward end, and in double radial bearings at its rear end. The differential shafts at their inner ends are carried in big radial and thrust bearings and at the outer ends there are big diameter radial bearings well spaced so that all the load is carried between the two bearings. Except that final drive is by means of Gleason gears, this rear axle does not differ in any essential features of design from the special axles used on Delage racing cars.

The underslung rear springs are three-quarter elliptic type, with a width of 2½ in. and a length for the main leaf of 51 in.

The front axle is also the outcome of racing experience. The steering knuckles are castor type, the pivots being so inclined that if their axis were extended it would cut the vertical axis of the wheel at the point of contact of the tire with the road. The steering pivots have double ball bearings top and bottom, as well as a thrust bearing, while the front wheels have widely spaced spherical radial bearings, with a double thrust bearing between the two.

Training Operatives

DURING the continuance of the war the National Government was vitally interested in having every factory engaged in an essential industry, operate at the highest possible efficiency. Consequently, the U. S. Department of Labor organized a training service, the object of which was to teach factory workers the best and most productive methods of doing their particular job. It is claimed that most remarkable results were achieved in some instances. Operatives who had been doing a certain task for years in some instances, turning out a certain number of pieces per hour, by being trained to improved methods for a week, increased their production 30, 50, 70 and even 100 per cent. According to H. E. Miles, who was in charge of this work and who spoke on it at the National Conference of the Society of Industrial Engineers in New York last week, the usual method of the service consists in segregating a certain amount of equipment for training purposes and schooling operatives in improved methods. Inasmuch as the increased productivity leads to increased earnings, the operatives usually take to the plan with avidity. In cases where the operator is on piece work his earnings will increase in the same ratio as his output, while the employer will be benefited by a decrease in the overhead charges on his product.

This training service was a war activity and will be discontinued after June 30. We understand, however, that the service still has available considerable funds, which it is endeavoring to spend to the best advantage of the Nation. We believe that manufacturers in the automotive industries will be glad to take advantage of this opportunity. There is particular need for bringing our productive capacity up to the highest possible pitch in view of the approaching sharp competition in the world's markets. America pays higher wages than any other nation and in order to be able to compete in foreign markets it is necessary that its workmen should turn out more work in a day than those of other nations.

Proper training of operatives with a view to increasing their productivity, therefore, would seem to be a step in the right direction.

It will help the manufacturer in reducing his percentage of overhead, the employee in increasing his earnings and the country in meeting foreign competition in the world's export markets.

Don't Shackle Brains

TOO often a concern will search the country for the best bit of human brain power that it can secure along certain specialized lines, and then, after it has secured it, at a high price, will shackle it.

If you are sick and know how to cure yourself, you do not hire a doctor and pay him to listen to your diagnosis and method of cure.

If your business is sick or failing in a certain department and you secure the best man in that line to head that department, you must remember that you have not paid him to listen and to put into effect YOUR method of running that end of the business.

You had your chance before you called the specialist in. You needed him or else you would not have called him in. After you have got him, do not hog-tie his mentality and experience. Give him free rein. He has a reputation to make and support and he is going to do that by building up YOUR business in his particular department.

When you fail to allow your specialist to use his knowledge, when you make him subject to another who could not hold down his job before the specialist came, you are in a worse position than you were before, because you have secured little or no improvement and have the added expense of your new man. You have probably added the damaging feature of internal friction to your organization, and this is costly.

It pays to hire the best men you can get. They are your tools and the quality of work is closely governed by the quality of the tools that produce it.

After you have gotten your men, let them use the qualities which led you to employ them.

Imaginary Spring Wheel Losses

IN spite of the many agencies at work spreading enlightenment on mechanical matters, certain fallacies seem to have a very deep-rooted hold on the public mind. One of these is that a spring wheel in which the spokes are free to expand and contract lengthwise, and in which when the load is applied the axle is eccentric to the rim or tire, is hard rolling, producing the same effect on the level as when a vehicle with rigid wheels is ascending an endless hill. The supposition is that the spring wheel will be similar in its action to a rigid eccentric wheel when it is attempted to move the wheel out of the position in which it will naturally come to rest on account of its eccentricity.

Now, the spring wheel and other elastic wheels have proven a rather mediocre success, and undoubtedly as at present constructed they possess many defects, but that of a continued serious loss due to the eccentricity of the wheel is not one of them.

As one contractible spoke after another nears the lowest position, it is, of course, compressed by the load, and a certain amount of energy is stored up in it. As it is the forward motion of the wheel that causes this energy to be stored up, it is supposed that this energy has to be supplied either directly by the engine or from the kinetic energy of the vehicle, which would justify considering these spring spokes a drag on the vehicle. However, as soon as the spokes pass the lowest position they expand again, the energy stored up in them is released and is expended in moving the vehicle ahead. The effect is the same as when a rigid eccentric wheel seeks its natural position of rest. The energy thus gained is equal to the energy previously lost in compressing the springs.

Another way of looking at the matter is as follows: The amount of energy stored up in the spring spokes of the wheel always remains the same, as the compression and extension of springs goes on simultaneously and always at the same rate. There is therefore no need for drawing energy from an outside source. The only possible loss would be that attending the compression of springs. Steel, if worked within the elastic limit, is an almost perfectly elastic medium, and whatever molecular friction there may be is negligible from a practical point.

Motion Picture Commercial Propaganda

THE plan of the Department of Commerce to exhibit motion pictures of American industries abroad is an excellent one and should receive the co-operation of every manufacturer with foreign commerce ambitions. Great Britain and Germany have both realized the value of the motion picture abroad, and the time is ripe now for American manufacturers to immediately adopt similar methods. Before the war the Germans were commercially well established in Japan, due chiefly to the display of motion pictures of their industries, while no propaganda was made for the United States, and American trade suffered accordingly.

Reports from abroad indicate a keen interest in industrial pictures and state that films devoted especially to road construction and the manufacture and uses of automotive products will be welcomed. In fact, when the American Association of China recently displayed industrial films in Shanghai the theater was filled to overflowing despite unfavorable weather. Possibly the National Automobile Chamber of Commerce, acting for the majority of the manufacturers, can take this matter up directly with its members and act as the medium for securing motion-picture films for the Bureau of Foreign and Domestic Commerce.

Pressed Steel in Trucks and Tractors

IN passenger car manufacture pressed steel parts now occupy an important place. Frames, rear axles, tanks, mufflers, oil pans and many other parts are very generally made of this material, and the application of pressings is constantly gaining ground. The chief advantage of pressings is that they permit of lighter construction than parts made by other methods at equally low cost. It has therefore been a question whether in other branches of the automotive industry, where low weight is not such an urgent requirement as in trucks and tractors, there would be a field for pressed steel parts. It will be remembered that it took a very long period before the pressed steel frame obtained a firm footing in truck construction. Structural steel was said to be much better, possessing greater ultimate strength, partly owing to a higher carbon content and partly to the improvement of the molecular structure by the rolling operation. However, to-day the pressed steel frame is firmly established in the truck field, and it is even being used on tractors. Probably the next step will be the production of pressed steel axles for trucks. At the present time most truck axle housings are made of cast steel. If pressed steel is superior to cast steel for passenger car axles, why is it not superior for truck axles also? The only possible reason that occurs to us is that the thickness of metal required in the former is below that which can be successfully cast in steel, while that required in the latter is not. It does not require much foresight, however, to predict that the problem of pressed steel truck axles will be attacked and successfully solved, not only technically, but commercially as well.

Latest News of the

3227 De Haviland 4's Produced

457 in Front Lines on Day of Armistice — Cancellations of $480,000,000 to March 19

WASHINGTON, March 25—Up to the signing of the armistice 3227 De Haviland 4 planes were produced, of which number 628 were in actual service at the front, 1885 floated for delivery to the A. E. F., and 1025 assembled over seas for service. Four hundred and fifty-seven were in actual front line duty on the day the armistice was signed.

Aircraft contract cancellations up to March 19, 1919, exceeded $480,000,000, of which 52 per cent were for engines and spare parts and 35 per cent for airplanes and spare planes, the balance being for accessories, balloons and supplies.

Following is the tabulation showing the number of De Haviland planes produced and in service, and the various values of contracts canceled and suspended.

	Number	Per Cent of Total Production
Produced	3,227	100
Floated	1,885	58
Received at French ports*	1,185	37
Assembled overseas	1,025	32
Put into service overseas	984	30
Put into service at front	628	19
In commission at front†	457	14

*To Nov. 1, 1918.
†To Nov. 3, 1918.

VALUE OF CONTRACTS CANCELED AND SUSPENDED TO MARCH 19

	Value	Per Cent of Total
Engines and spare parts	$250,409,982	52
Airplanes and spare parts	167,554,386	35
Chemicals and chemical plants	19,852,370	4
Instruments and accessories	13,832,902	3
Balloons and supplies	10,071,035	2
Fabrics, lumber and metals	7,968,324	2
Miscellaneous	11,041,132	2
Total	$480,730,131	

Oil Exports Decrease

WASHINGTON, March 26—The effect of the armistice on oil exports is readily displayed by the export figures for February, 1919. Gasoline exports total 26,964,764 gal. in February, 1919, as compared with 35,396,038 gal. in the same month of 1918. Kerosene and lubricating oils increased in February, 1919. Mineral oil exports for February, 1919, total 165,889,425, as compared with 221,579,890 gal., worth $24,031,982, which were exported in February, 1918. The greatest decrease, as compared with 1918, is noticeable in the exports of fuel oil, which decreased from 118,863,438 gal. in February, 1918, to 36,710,850 gal. in February, 1919.

Will Sell Copper for War Department

WASHINGTON, March 26—The United Metal Selling Co., representing the copper producers, has arranged with the War Department to sell 100,000,000 lb. of copper belonging to the department, and also whatever copper scraps the army has to dispose of. Not less than 5,000,000 lb. of copper will be delivered by the Government to the copper producers each month for a period of 10 months, and then 10,000,000 lb. per month will be delivered for a period of 5 months.

No Action on Saxon Plan

NEW YORK, March 27—A meeting of stockholders of the Saxon Motor Car Corp. was held yesterday to vote upon a proposed re-organization plan prepared by the creditors. Inasmuch as only 6000 shares of the total of 60,000 shares outstanding were represented, no formal action was taken.

New British Commercial Organization

WASHINGTON, March 26—British Manufacturers' Association has organized a Federation of British Industries numbering 16,000 firms which will cooperate with its members on foreign trade. The organization will appoint overseas trade commissioners. A beginning has been made in Spain. These commissioners are to be men of commercial qualifications, conversant with the customs and commercial needs of the countries to which they are appointed.

233,881 War Motor Vehicles Ordered

90 Per Cent Delivered to Government Included 96,551 Trucks and 20,037 Cars

WASHINGTON, March 24—Ninety-six thousand, five hundred and fifty-one motor trucks were delivered to the United States Army up to Feb. 1, 1919, according to figures made public to-day by the War Department. Of this number 51,784 were shipped to France and 44,767 have been distributed in the United States.

Included in the total number delivered were 37,891 class B 3-ton standardized trucks, 15,084 Class A 1½-ton trucks and 24,095 four-wheel drive trucks. Eleven thousand B trucks remained on order, of which number all but 7348 have been canceled. In addition 5137 four-wheel drive, 3772 Class AA ¾-ton and 2329 Class A 1½-ton trucks still remain on order.

Highest per Cent of Cars Delivered

In all there were 233,881 trucks, passenger cars, ambulances, motorcycles, trailers and bicycles ordered by the Government, of which 90 per cent were delivered, the highest delivery per cent being that of passenger cars, of which 20,038 were ordered and 20,037 were delivered. Fifty-six per cent of the 37,891 B trucks delivered were shipped to France.

Following is the complete tabulation showing the status of motor vehicle contracts delivered up to Feb. 1, 1919:

MOTOR VEHICLES DELIVERED AND REMAINING ON ORDER
FEBRUARY 1, 1919

Automotive Industries

Steel and Iron Prices Reduced

Expected to Stimulate Buying—Pig Iron Reduced $4.25, Billets $5 and Rails $10 a Ton

NEW YORK, March 21—Basic prices of iron and steel have been reduced considerably below previous current prices, though the reduction is not as great as was expected in some quarters. The reductions range from $4.25 per ton on pig iron and $5 on billets to $10 on standard rails; they amount to $7 per net ton on plates, shapes, bars, wrought pipe, sheets and tin plate, and to $5 on wire, wire nails, hoops and light rails. The new prices become effective at once and amount to 10 to 14 per cent.

It is expected that the lower prices, which are minimum, though the prices set by the War Trade Board were maximum, will stimulate buying. For the past 6 weeks the iron and steel markets have been weak due to the holding up of orders on the part of purchasers in anticipation of the reduced price. On this score *Iron Age* says:

"The opinion is general in the steel trade that the reduced prices will bring out in the near future a moderate amount of new business which buyers have held up since the stabilizing movement loomed up about 6 weeks ago.

"Willingness to co-operate with the Government to secure a stable market and the largest possible operation of iron and steel mills is shown both by producers and manufacturing consumers. It is yet to be developed how far the reductions will go in stimulating a demand over and above what has accumulated, and whether the new prices can be maintained as minimum through the year, as proposed in the Washington program."

No Heavy Steel Buying in Detroit

DETROIT, March 27—The new steel prices have not stimulated any heavier buying by Detroit manufacturers as yet. They are still purchasing what they need, from day to day, and are awaiting further developments. They declare that steel must come down lower, but can hardly see any hope of a further reduction for some time to come. There seems to be some apprehension as to whether the new prices are in violation of the Sherman anti-trust law, and it probably will be some time before the true sentiment in and around Detroit can be gaged.

Klingensmith on Vacation

DETROIT (Special Telegram)—March 26—F. L. Klingensmith, vice-president of the Ford Motor Co., has left Detroit to take a long vacation. It is rumored that he has either severed his connection with the company, or that he will do so shortly.

Coffin Leaves France

PARIS, March 1—Howard E. Coffin is leaving Paris this week for New York via England. Mr. Coffin has been on this side for the past 3 months and has travelled extensively in England, France, Italy and occupied portions of German territory. Mr. Coffin has been particularly interested while in Europe in everything concerning aviation development, and particularly the role which America will play in the coming conference to decide on international agreements regarding air navigation.

It is understood that Mr. Coffin will spend but a short time in America in order to attend to his private business matters and then will return to Paris.

Will Control Air Equipment Sales

WASHINGTON, March 25—The Salvage Branch, Supply Section, Division of Aircraft Production, has been charged with complete responsibility in all matters pertaining to the sale of surplus and obsolete air service equipment, and no sales will be made in the future until the salvage branch authorizes them.

U. S. Chamber Aids Employment for Soldiers

WASHINGTON, March 24—The United States Chamber of Commerce is asking for the co-operation of all commercial organizations to assist in placing returning soldiers and sailors in employment. The chamber plans to establish a bureau for the purpose of expediting the co-operative work of the various organizations toward alleviating the existing employment problem.

February Exports Are Excellent

January's Figures Were Good, but They Are Surpassed by Last Month's

	Cars	Value	Trucks	Value	Parts
Feb.	3,041	$3,719,485	1,403	$4,270,542	$2,699,741
Jan.	2,137	2,916,381	907	2,375,584	2,406,783
			1918		
Feb.	3,584	3,079,191	766	1,917,638	1,962,797

WASHINGTON, March 26—In AUTOMOTIVE INDUSTRIES of March 6 it was pointed out that our automotive exports for the month of January, 1919, augured well for the future of our overseas trade. The February figures given herewith tend to confirm that prophesy—they show appreciable advances in cars, trucks and parts when compared with the totals for the previous month.

For the time being our exports to the United Kingdom are in bad shape, due, doubtless, to the embargo which is in force. It is not anticipated, however, that the present restrictions will be maintained for any considerable time, and there is ample evidence of a strong demand for American cars and trucks in Great Britain.

In view of statements made recently to the effect that Australia would give preference to automotive products of British origin it is satisfactory to observe that during February Australia was our best customer for passenger cars.

Truck exports are practically double those of January, but the distribution is far from satisfactory, in the sense that many countries capable of buying commercial vehicles from us — countries which have industries needing up-to-date road transport — are not purchasing regularly.

General Motors Buys Another Plant

Takes Over Inter-State Buildings and Land—For Parts Manufacture

MUNCIE, IND., March 22—General Motors has bought the fiscal property of the Inter-State Motor Co., including the plant and 40 acres of land adjoining it. It is expected that this property will not be used for the manufacture or assembly of cars, but of parts, although the plant readily would lend itself either to the manufacture of assembly of cars or the building of bodies. However, there is no doubt that with the plant and adjoining property General Motors has acquired the nucleus of another large unit of its vast activities. This also is taken to mean that there will be no more Inter-State cars and the company automatically will cease to do business.

The Inter-State company was one of the first to discontinue the manufacture of cars for the duration of the war early in 1918. It was announced at that time that the company would place on the market 1 and 1½-ton trucks instead. However, the company took on contracts for artillery tractors and had only tooled up for production when the armistice was signed. As a result peace found it totally unprepared to resume commercial work, and it notified its distributers and dealers that they should not depend on deliveries for several months to come. It was expected then, however, that when the company had completed the 15 or 20 per cent of the Government orders, which it planned to do, and had re-converted the plant back to cars, a much improved car would be marketed.

—

Germany Preparing for World Markets

WASHINGTON, March 19—German manufacturers realize and are preparing for a new and hard commercial war to follow the signing of peace, according to advices received here, and a network of organizations has been created to assist German industry. The Technikische Meese G. m. b. H. (Technical Fair) has been organized in Leipzig to promote the interests of numerous makers of tools, machinery, factory equipment, etc., and will develop German inventive genius.

The Company for Home and Foreign Undertaking, Hamburg, with a capital of $5,950,000, plans a series of measures to revive trade abroad, and especially in the Balkans, the Caucasus and Persia. The Austro-German division of this company plans to develop Turkey for German trade. Likewise the Institute of Navigation and World Business, with a membership of 4300 manufacturers, and the United League (Die vereinigten Verberde) are planning world-wide advertising and selling activities.

Technical magazines published in English and other languages are planned to stimulate foreign business, and will be especially devoted to extolling German manufacture and the low prices of German made goods.

—

Sarles Wins Ascot

LOS ANGELES, CAL., March 23—If the Santa Monica Road Race a week ago and the Ascot Speedway to-day are taken as indications, racing this year will attract more persons than ever, for fully 50,000 saw Sarles take the 150 miles at better than 71 m.p.h., which was a new track record. He drove his Roamer Special and won in 2 hr., 7 min., 2 sec. Hearne in a Chevrolet won second, Pullen third in a Hudson, and Durant in a Chevrolet fourth. The fourth man finished less than a minute after the winner. Toft and Lewis were still running at the end, but Lecocq, Elliott and Thomas had been eliminated by mechanical trouble. There were no accidents.

The new track record is considered very good indeed in view of the fight Sarles had to put up. Three stops for tires delayed him as he was using re-treaded tires that for a time littered the track, but he finally changed to others.

DePalma had intended to try for the track record, but in practice yesterday he damaged his steering gear so to-day he only drove a 5-mile exhibition.

—

Transatlantic Flight Rumored

WASHINGTON, March 21—Many reports are current here of possible flights across the Atlantic, some to the effect that these will be tried shortly, and one that France is even now preparing to send a pilot across. Great Britain, it is reported, has a huge plane with a 375 hp. engine already at St. Johns, Newfoundland, and will make the trial to Liverpool —about 1300 miles—in the next few days. Several American pilots are said to be making tests preparatory to making the trip, and it is said that Lt.-Com. P. L. Belinger, in charge of the air station at Norfolk, will try to negotiate the long distance flight within the next 10 days in one of the big navy flying boats. There is no definite news, however, on this subject.

—

Oregon to License Mechanics

SALEM, ORE., March 21—Automobile mechanics hereafter will be licensed in the State of Oregon. The State Legislature has passed Senate Bill No. 280, which creates a "board of auto mechanics examiners" before whom those who would work as mechanics must appear, be examined, passed and properly licensed—for a fee of $5; the license is good for a year, when it can be renewed and "the board may at any time revoke a license . . . for incompetency on the part of the holder . . . and for any other good and sufficient cause."

—

Republic Trucks for Canada

ALMA, MICH., March 24—The Republic Motor Truck Co. is about to enter the Canadian automotive field. B. D. Jones resigned as sales manager to become general manager for Canada. The company will locate its plant in Windsor, Walkerville or Toronto.

Stephens Distributers Set Policies

Men Who Sell Given a Voice in Design and Production—Co-operative Spirit

FREEPORT, ILL., March 21—It is not an uncommon belief among dealers that there is too little attention paid by the engineering and designing departments of the motor car factories to suggestions from the distribution end of the business. This feeling is not unwarranted in some cases. Too often the designing department forgets that the distributers' and dealers' suggestions reflect the ideas of the owners.

More frequently, however, there are production and material difficulties which prevent the practical carrying out of the suggestions, but which the factory does not trouble itself to explain to its dealers.

Sometimes, also, the distribution is not a unit as to what it wants. Local conditions frequently reflect themselves in a demand for a certain feature in one territory, a feature which is directly opposite to the needs of another section.

Close co-operation between its distributing and manufacturing departments seems to have been worked out by the executives of the Stephens Motor Branch of the Moline Plow Co. in a way which gives the factory the benefit of the dealers' and distributers' first-hand information as to the needs of their territories and at the same time shows that their suggestions are given thorough consideration.

This was shown forcibly in the annual distributers' conference at the factory this week. Having a comparatively small number of distributers, each representing a large number of dealers, it is possible for the distributers to get together with the representatives of all the different departments of the factory and thresh out the pros and cons of all suggestions in open meeting. Consequently a feature of the three-day meeting was a series of "round-table conferences" in which all hands participated, with Sales Manager Clough in the chair.

They were really round-table conferences, for there were provided a number of small round tables with pads and pencils on each for the conferees to make notes. Each distributer was called on in turn to give his ideas on the point at issue—say, the color of the wheels—and when the distributers themselves did not agree the meeting was turned over to them until they decided what they did want. If what they wanted was not feasible from a factory standpoint they were told frankly why.

Also, they got first-hand information from the factory. Not only was Stevens' Plant Manager Leonard there, but the body man, the service manager, the engineman, etc., were on hand. In addition representatives from the factories making the units from outside were on the job to help out.

When, after the conferences, the distributers left town, they knew that the factory was doing everything possible to meet their ideas. Incidentally, it is only fair to say that AUTOMOTIVE INDUSTRIES' representative never attended a dealer's meeting at a factory at which there was less kicking. This, it is believed, is due in a measure to the fact that the distributers were taken into the confidence of the factory.

Nebraska Legislates for Tractor Maintenance

LINCOLN, March 24—Legislators in Nebraska have introduced two bills which at least have novelty if nothing else, but which if passed would cause a lot of trouble.

The first of these is "Nebraska S.F. No. 86." Under its terms every person selling farm tractors in Nebraska must carry within the confines of the state a stock of repair parts sufficient to keep such machines in repair. Failure to do so makes any selling transaction void. The same provisions cover sales of motor cars.

The other, which is styled "Nebraska H. T. No. 85," provides for official tests of all tractors and would compel the maintenance of adequate service stations. According to the bill, every make and model of tractor offered for sale in the state must be officially examined and tested and passed upon by a board of three competent engineers under the control of state university management. Tests would be made of endurance, official rating of horsepower and fuel consumption per acre plowed. The bill also requires that an adequate stock of repair parts be carried, and failure to comply with the provisions bars offenders from doing further business in the state.

Lists of Automobile Importers

WASHINGTON, March 24—The Department of Commerce has received lists of importers of automobiles and accessories who are interested in communicating with American manufacturers. They are located at Batavia, Dutch East Indies; Bombay, India, and Hongkong, China. Manufacturers can secure the lists and further information by addressing the Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington, and referring to file numbers 9504, 9521 and 9510.

Kearns Has New 1½-Ton Chassis

BEAVERTOWN, PA., March 24—The Kearns Motor Co. is now building a 1½-ton truck with a Continental four-cylinder 3½ x 5 engine. Standard parts are assembled in the job, and the specifications include high tension magneto, Borg & Beck clutch, Hotchkiss drive, Muncie three-speed gearset, semi-elliptic springs, 136-in. wheelbase, solid tires 34 x 3½ in. front, 34 x 5 in. rear. The drive is internal gear, and roller bearings are used in the front wheels.

English Tractor Trial Rules Defined

Exhibition Planned for August by Motor Manufacturers and Traders

LONDON, March 14 (Special Correspondence) — The Society of Motor Manufacturers and Traders has decided to hold its annual farm tractor trial during the month of August. Rules have been drawn up which differ slightly from those in previous years. The complete regulations follow:

Resolved, that not more than two machines of any type should be entered, and that each machine should be observed by local farmers.

(a) Draw bar pull to be taken by dynamometer. Load to be added till dynamometer records "Stop." The technical adviser to settle speed at which pull to be taken.

(b) Fuel consumption in connection with price to be observed. Fuel, lubricating oil and water to be booked out daily.

(c) Ease of handling to include time in starting after machine left in open over night, uncovered. Also steering and distance in turning.

(d) Weight re drawbar efficiency to be taken in full working order on weighbridge.

(e) Reliability—All time lost in a working day to be recorded, except in stops for accident to plow, etc.

(f) Cost to be declared and a guarantee to be given of supply during current season at price declared. (Technical adviser to work out cost per drawbar-horsepower—not brake horsepower.)

(g) General design—Simplicity of construction and accessibility to all parts.

(h) Facility for use of any other fuel than gasoline. Entrants to notify amount required in advance, and supply to be controlled by the society.

Plows—Resolved to invite plow manufacturers to offer facilities for demonstration by the entrants, informing them that nothing beyond 12 in. wide would be acceptable and that the depth of plowing would be 6 to 8 in.

Dynamometer tests to be made 2 days before trial to show how many furrows could be drawn.

To Make War-Born Products

NEW YORK, March 21—The Aircraft & Motor Products Co. has been formed here, with offices at 299 Madison Avenue, and will manufacture products for aircraft and motor vehicles that have been developed primarily from successful war products. The company has developed a spark plug, has a line of cup greases and gear oils, a bronze bearing metal and will manufacture aluminum castings, bronze castings and gears. Rayburn Clark Smith of Philadelphia is president, other officers being: Vice-president, H. Allen Dalley, Philadelphia; general manager, Major Harry A. Budd, New York. Branches have been established in Philadelphia and Chicago. The company will brand its products "A-A."

New United States 1½-Ton Truck $1,995

CINCINNATI, March 20—The United States Motor Truck Co. has added a 1½-ton truck to the United States line, and with the new addition the line comprises capacities from 1½ to 5 tons. This smallest model is to sell for $1,995 in chassis with seat, solid tires and regular equipment. The name will be Model N. The engine is a four-cylinder block type with 3¾-in. bore and 5-in. stroke. Cooling is by a centrifugal pump, a vertical tube radiator having cast tanks and a cast frame. The engine is three-point suspended in the frame, the third point being around the starting-crank housing and the rear support arms having recoil springs. The engine is designed to take an electric starting and lighting system, and this may be had at extra cost. The dry-plate clutch and the three-speed gearset are a unit with the engine.

Internal gear drive is used in the axle and all the brakes are on the rear wheels. The steering wheel is on the left side with the control levers in the center. Tires are 36 x 3½ front, 36 x 5 rear. Wheelbase is 120 in.

New Reliance Production Plans

APPLETON, WIS., March 24—The Reliance Motor Truck Co., which recently reorganized its board of directors and official personnel, has perfected the organization of its engineering and production staff. Beginning with the delivery of its first truck to-day, the company is now on a regular production basis of one chassis a day.

Oscar Stegeman has assumed the position of chief engineer. H. F. Vahl is the new production manager. The present output of Reliance trucks is confined to a 1½-ton model, but after July 1 a new 2½-ton design will be put into production, and later a 3½-ton design will be included in the line. The company also has arranged to engage in the output of a truck axle, which is being marketed under the name of Badger external spur gear drive axle, in 1½, 2½, 3½ and 5-ton types. The same axle is used in Reliance trucks. John M. Balliet, Appleton, is president and general manager of the Reliance company.

Kelsey Wheel Has $2,067,904 Surplus

DETROIT, March 22—A surplus of $2,067,904 is shown in the Kelsey Wheel Co.'s financial statement for the year ended Dec. 31 last, after all necessary deductions were made and $355,022 put aside as provision for federal taxes. This amount is $583,229 ahead of 1917 surplus. $1,565,625 is still due from the government for war contracts.

Consolidated balance sheet of Kelsey Wheel Co., Inc., and subsidiaries, as of Dec. 31, 1917 and 1918, compares as follows:

Assets

	1918	1917
Plant equipment, etc..	$2,457,577	$2,519,509
Patents, good will, etc.	10,000,000	10,000,000
Investments in other companies	59,000	....
Inventories	2,104,089	2,212,839
Notes and accounts receivable	841,970	932,508
Cash	222,474	383,830
Due from U. S. Government	1,565,625	....
Liberty bonds, etc.....	176,083	65,347
Insurance premiums ..	14,644	10,475
Deferred charges	88,257	49,454
Total	$17,529,719	$16,123,960

Liabilities

	1918	1917
Preferred stock	$2 909,000	$3,000,000
Common stock	10,000,000	10,000,000
Notes payable	1,090,000	290,000
Accounts payable	832,338	788,315
Sundry creditors, etc..	275,455	234,383

Surplus	2 067,904	1,484,675
Total	$17,529,719	$16,123,960

Gray & Davis Make Up Dividends and Retire Stock

BOSTON, March 26—The remaining dividend of $1.75 in arrears on preferred, and the regular quarterly dividend of $1.75, will be paid by Gray & Davis, Inc., on April 1 to stockholders of record March 21. The directors of the company have also voted to carry out the agreement made in February, 1918, with the preferred stockholders' committee to purchase on April 1 all preferred stock deposited with the committee at 103 a share and accrued interest. At the date of the directors' vote $439,400 out of a total issue of $600,000 was deposited with the committee. At present about $440,000 has been deposited with the committee, and will be retired on April 1. As there is only $600,000 preferred outstanding, by April 1 only about $150,000 will remain outstanding.

A few weeks ago a merger with the American Bosch Magneto Co., Springfield, was seriously considered, but called off at the last minute by mutual consent.

Prepare for Trans-Atlantic Flight

WASHINGTON, March 25—That the final preparations for a trans-Atlantic flight under the direction of the United States Navy are being completed is evidenced by the present search for a starting field by the Navy Department. A destroyer has been sent out to locate a suitable harbor or starting field, and Lieutenant-Commander Bellinger, who was detailed to assist in the project, is co-operating with the destroyer. It is now expected that there will probably be a fleet of four flying boats in the attempt.

$998,887 Aviation Equipment Sold

WASHINGTON, March 26—Airplanes valued at $319,000 and airplane equipment valued at $679,887 were sold between March 8 and March 14 by the War Department, through the Director of Sales. The Motors and Vehicle Section sold equipment, accessories and a kitchen trailer for $1,298.10 during the same period. No trucks or passenger cars have been sold. Other sales made during this period were: Oils, greases, etc., valued at $35,228.48; machinery and machine tools, together with engineering equipment, $224,824.85; ferrous metals, $71,977.96, and non-ferrous metals, $34,591.83.

Steele Goes With Dominick

NEW YORK, March 27—Charles M. Steele, who for some years has been out of active touch with the automobile industry, and who was formerly vice-president of the Carl M. Green Co., has associated himself with Dominick & Dominick, financial brokers in this city.

Dividends Declared

Goodyear Tire & Rubber Co., Akron, first preferred, quarterly dividend of 1¾ per cent, payable April 1 to stockholders of record March 15; second preferred, 2 per cent, quarterly, payable May 1 to stockholders of record April 15.

Edmunds & Jones Corp., Detroit, 1¾ per cent, quarterly, preferred, payable April 1, to stockholders of record March 20.

MacDonald in Charge of Federal Road Work

WASHINGTON, March 26—Thomas H. MacDonald, chief engineer of the Iowa State Highway Commission, has been appointed by the Secretary of Agriculture as engineer in immediate charge of the work under the Federal Aid Road Act, which provides for co-operation between the states and the Federal government in the construction and improvement of roads. Mr. MacDonald will assume his new duties as soon as he can close up his work in Iowa.

He will supervise and direct all the activities of the Bureau of Public Roads under the Federal Aid Road Act, including the expenditure of the additional appropriation of $209,000,000 provided by the Post Office Appropriation Act for the extension and development of highway construction during the present and the next two fiscal years.

For the time being he will devote his energies to the problems arising under the Federal Aid Road Act incident to the sumption and extension of road work.

Not to Take Over New Process

NEW YORK, March 24—In a news item last week it was stated that "The Meecham Gear Corp. has been organized to take over the New Process Gear Corp." The statement was incomplete and misleading due to the inadvertent omission of a word. It should have read "The Meecham Gear Corp. has been organized to take over *from* the New Process Gear Corp. the manufacture of rawhide pinions," etc.

Hemingway Succeeds Bradley as Manager of M. A. M. A.

NEW YORK, March 24—L. M. Bradley, who since October, 1916, has been manager of the Motor Accessory Manufacturers' Association, has resigned. Early in December he was granted a three months' leave of absence because of illness and immediately left New York for Sea Breeze, Fla., where he is at present. M. L. Hemingway, who about a month ago was appointed assistant manager, will succeed him. Prior to his connection with the M. A. M. A. Hemingway was with the Rubber Association of America.

—

Price New Safety Council Manager

CHICAGO, March 24—C. W. Price has been elected general manager of the National Safety Council to succeed W. H. Cameron, who has resigned to become manager of Industrial Relations for the Eastman Kodak Co. Mr. Price has been field secretary for the council for some time.

—

John F. Koch, treasurer of the Evinrude Motor Co., Milwaukee, died March 17 at Los Angeles, where he went late last fall for his health. Mr. Koch was 45 years of age.

—

E. L. Moorman, Beloit, Wis., has become manager of the sales department of the Highway Trailer Co., Edgerton, Wis. He has been sales manager of the Beloit Gas & Electric Co. for many years.

—

W. P. Berrien, formerly with the Firestone Tire & Rubber Co., and the Batavia Rubber Co., and also with the Star P. & V. Corp., which has recently merged with the Allied Industries Corp., will devote all his time to the automotive lines in the new relation.

—

P. E. Barker, who was formerly experimental engineer of the Northway Motor Manufacturing Co., and more recently research engineer at the Aluminum Castings Co., Cleveland, is now in charge of the truck and motor equipment department of the Van Dorn Iron Works Co., Cleveland.

—

Dale E. Eller, who has been a lieutenant in the field artillery, and **Howard M. Benedict**, who has been a lieutenant in the air service, have been honorably discharged, and have returned to their positions with the Oakes Co., Indianapolis. Mr. Eller is connected with the sales-engineering department, and Mr. Benedict with the pressed steel stamping department.

—

Lt. E. A. Wales, formerly chief of production, motors division, Quartermaster Corps, Cleveland, has re-entered the employ of the Raybestos Co., Bridgeport, Conn., and will resume his pre-war duties as manager of its Detroit office at 1713 Dime National Bank Building.

Men of the Industry

Changes in Personnel and Position

Lawrence W. Enos, until recently a lieutenant in the Quartermaster Corps, has joined the Firestone Steel Products Co., Akron, as manufacturers' representative in the Detroit district. Before entering service he was with the Steel Products Co., Cleveland.

—

Walter P. Hanson has joined the Haynes Automobile Co., Kokomo, as assistant advertising manager. Before his enlistment in the navy he was a newspaper and magazine writer.

—

C. H. Breaker has been appointed sales manager of the Diamond Chain & Manufacturing Co., Indianapolis. For the past year he has been in the air service, and for 9 years previous was with the Larkin Co.

—

H. S. Benjamin, for some time advertising manager for the Holley Kerosene Carburetor Co., Detroit, has resigned and has been succeeded by Earl Holley. Mr. Benjamin's future plans have not been announced.

—

W. S. Butler has received his discharge from the army and has joined the district sales manager's staff of the Commerce Motor Car Co., Detroit.

—

G. E. Wirsching, formerly with the General Motors Export Co., has been made assistant to E. F. Sayers, general manager of the export division of the Garford Motor Truck Co., Lima, O.

—

Harry J. Sproat has been made secretary and factory manager of the New Way Motor Co., Lansing. He was formerly manager for the Olds Motor Works.

—

G. B. Sharpe, New York, has been appointed assistant sales manager in charge of advertising for the Cleveland Tractor Co., effective April 1. He has been in charge of the advertising and sales promotion for the De Laval Separator Co.

—

J. R. Hall, for seven years production engineer with the Chandler Motor Car Co., Cleveland, has been appointed production manager for the Cleveland Automobile Co.

—

G. B. Sharpe has been appointed assistant general sales manager of the Cleveland Tractor Co., Cleveland. He will have charge of advertising and sales promotion.

—

F. A. Falkenbach, sales manager of the Modern Tool Die & Machine Co., Columbus, died at Youngstown on March 14.

Ford Organization Shaken by Recent Resignations

DETROIT, March 24—John R. Lee is the latest official to resign from the Ford Motor Co. His resignation came Thursday, following closely that of Harold Wills, chief engineer and production head, who severed his connections earlier in the week. Mr. Lee has not made known his future plans, but states he will probably remain in the automotive industry.

Ever since Norval A. Hawkins, sales engineer, quit the Ford company several weeks ago, automotive circles have been full of rumors concerning administration changes at the Ford company, and, needless to say, these changes are coming with startling rapidity, and the Ford organization is said to be quite seriously shaken.

John R. Lee worked out the profit sharing and wage adjustment policy of the Ford company. He was also the head of the sociological work, which attracted the attention of manufacturers and large employers of labor everywhere. When this country entered the war Mr. Lee represented the Ford Motor Co. in Washington, being the point of contact between his company and the government. He was a member of the Automotive Industries Committee created to represent the motor car industry and to assist both the government and the manufacturers in placing and executing ammunition contracts. He was a member of the executive committee of the Ford Motor Co.

Before joining the Ford organization eight years ago, he was president of the John R. Keim Mills, Inc., Buffalo, manufacturers of pressed steel products. This company was purchased by the Ford company and moved to Detroit.

—

W. H. Diefendorf, Syracuse, has resigned his position as chief engineer and director of the New Process Gear Corp. and is now with Weeks-Hoffman Co. of that city.

—

I. B. Meers has been appointed general sales manager of the Panhard Motors Co., Grand Haven, Mich. He will handle export affairs as well as American sales.

—

A. E. Vinton, connected with the National Motor Car & Vehicle Corp., Indianapolis, for the past 12 years as assistant sales manager and later as export manager, has been appointed general sales manager for the New Jersey Car Spring and Rubber Co., Jersey City, N. J.

—

F. X. Newman has resigned his position with the Wright-Martin Aircraft Corp., New Brunswick, N. J., to become vice-president and sales manager of the Automatic Safety Tire Valve Corp., Long Island City.

—

Lou J. Sackett, a car salesman for the past 23 years, has resigned from the Cadillac Co. of New England, but has not as yet announced his future plans.

Pros and Cons of British Import Restrictions

LONDON, March 10 (Special Correspondence).—Although no definite action has been taken by the British Government in regard to removing the prohibition of automobile imports, present indications seem to point to the adoption of some sort of a rationing plan on the basis of 1914 imports. In other words, taking the 1914 imports as about 1800 cars, it is expected that the government will permit some percentage of this amount to be imported.

British manufacturers are strongly against complete removal of this prohibition. It is their contention that the British industries require 12 to 18 months to resume pre-war status, and that American products should be kept away at least for the remainder of this year, or, if the rationing plan is adopted, only about 50 per cent of the number of cars imported in 1914 should be permitted to come in.

The importers point out that if it is the object of the government simply to prevent American importers having an unfair advantage over British manufacturers, the industry should be put back on the basis of 1914, and 100 per cent imports permitted.

—

South American Shipping Preferences Canceled

WASHINGTON, March 21—Ocean shipping preference procedure for the East Coast of South America has been canceled, according to an announcement made to-day by the War Trade Board. Steamship companies have been instructed to disregard any outstanding preferences heretofore granted.

This action has been taken because of information received that the allotment of shipping made by the Shipping Board for the East Coast of South America trade will be sufficient to take care of all the cargo now offered or which will be offered in the immediate future for these markets.

—

Automotive Restrictions in Holland

AMSTERDAM, HOLLAND, Feb. 27 (Special Correspondence)—Late in 1918 and early this year a shortage of gasoline in Holland, due to the exhaustion of supplies and the lack of imports, prohibited the use of passenger cars, trucks and motorcycles except for military purposes. In some of the big towns it was permissible to use cars for conveying sick persons to hospitals and for official business connected with the various foreign legations. Under ordinary circumstances oil and gasoline are comparatively cheap inasmuch as they are not taxed and supplies are received by tank steamer from America, India and Roumania principally.

In consequence of the impossibility of importing tires due to war restrictions, a tire industry has been started, and one factory, the Rubberfabrick "Vredestein," at Loosduinen (near The Hague), is bringing out what is described as a fair tire. This company is making only pneumatics and has not as yet attempted solids.

There are very few motor trucks in use in Holland. The greatest use of such vehicles is made by the war office. Private industry and commerce possess only a small number of trucks, and these cannot be used at present. Most of them are about 2-ton capacity, with a few 4 and 3½-ton vehicles. Light delivery trucks and those of 1-ton capacity are few.

—

Russian Buying Agency Established

SAN FRANCISCO, March 24 — The All-Russian Central Union of Co-operative Societies has been formed, with offices at 167 Post Street, to buy automotive products, etc., on behalf of Russian distributers, dealers and consumers, and to promote commercial intercourse generally through the control of that country's stocks of raw material. A request is made for duplicate catalogs and price lists.

—

France Lifts Import Restrictions

WASHINGTON, March 21—France has removed import restrictions from many commodities, including the following: Petroleum oils, crude and refined; heavy oils and other mineral oils; iron ore, copper ore, lead ore, tin ore, zinc ore, nickel ore, iron scrap, iron filings and copper sulphate, and wooden handles for agricultural implements.

Names of Foreign Consignees Unnecessary

WASHINGTON, March 22—Names of foreign consignees need no longer be included on the export bills of lading according to an announcement by the War Trade Board. It is believed that exporters are now thoroughly familiar with the enemy trading act and hence will not need to be checked up.

This table supplements the monthly tables of exports given singly for the last six months in AUTOMOTIVE INDUSTRIES, *and gives figures for all of the individual countries, including those generally grouped under the collective heading "Other Countries"*

Specifications for Trinidad Purchasers

WASHINGTON, March 22—A wheel track of 56 in., ground clearance not less than 8 in., wheel base between 108 and 125 in. and a turning radius of 20 ft. are the specifications demanded by the Trinidad automobile purchasers, according to the Trinidad Automobile Association, Trinidad, British West Indies. These specifications were the result of questions asked by the Association of British Motor and Allied Manufacturers of England, who are apparently planning to capture this trade.

New Zealand Ready for Car and Truck Imports

CHRISTCHURCH, NEW ZEALAND, Jan. 10—New automobiles are in great demand in New Zealand but are difficult to obtain, American cars being the only new ones on the market. As in America, automobiles are largely utility vehicles, 99 per cent of them coming under this classification in the country districts and 90 per cent in the towns and cities.

It is questionable what will be the attitude in New Zealand with regard to American and English cars after the war. There is a strong feeling that British cars will sell at better prices than American cars as soon as they are on the market, because the medium-priced British car retains its mechanical condition, finish, upholstery and smoothness of running much longer than the correspondingly-priced American car.

Farm tractors are not making much headway except in such areas as Canterbury Plains and one or two other parts of the South Island, where there are cultivated areas of fairly good size. In North Island the country is hilly and broken, and wet soil conditions have not proved suitable for tractor use. In a recent demonstration over such soil the tractor bogged on the first trip across the field, and as farmers here expect the tractor to be practically the same as a horse, there is not much prospect for its speedy advance.

One of the greatest difficulties in New Zealand is the shortage of good repairmen. The average motor mechanic, as he is styled here, is usually a half-trained person whose work is of low order.

Electric trucks are making great headway here due to the cheap current obtained from the government's water power system. In North Island, dairy companies are installing their own electric charging plants and using electric trucks for collecting cream from farmers. The use of the electric truck is accelerated because of the high price of gasoline, which is selling at 90 cents per imperial gallon.

Belgium Wants Heavy Import Duty

PARIS, Feb. 17—Automobile import duties in Belgium are still at pre-war rates, which is from 10 to 15 per cent of the value. Although France and England are free of duty it is believed that this will shortly be replaced by an import duty of 76 per cent in France, and 80 per cent in England, as a temporary measure which may remain in effect for one year.

Belgian manufacturers are not satisfied with this and have taken steps to bring it to the attention of the government, with the hope of obtaining an import duty about equal to that of France and England.

An endeavour has been made by Belgian automobile dealers to obtain licenses for the importation and sale of cars, to be given only to those persons who were actively engaged in the auto-

mobile industry before the war. It is claimed that large numbers of newcomers, who have absolutely no connection with the automobile industry, are now importing cars, to the detriment of men who have been in this business for a number of years.

—

Passes Oil Leasing Bill

WASHINGTON, March 22—The House to-day adopted the conferee report on the Oil and Mining Land Leasing bill which was described in a past issue of AUTOMOTIVE INDUSTRIES and which makes possible the leasing of 6,000,000 acres of oil lands owned by the Government. In payment for the leases by companies or individuals the Government will receive royalties and rentals and reserves the right to control and regulate the development.

—

Oil Found in England

WASHINGTON, March 22—The United States Fuel Administration has received information by cable of the reported discovery of oil in England. The cable states that considerable gas has been found, but no oil has yet been struck.

—

International Exhibits Scheduled

PARIS, March 10 (Special Cable)—At the first meeting of an International Automobile Manufacturers' Congress, held during the progress of the Lyons Fair, a circuit of automotive exhibits was arranged and dates set for the forthcoming French and English shows. The congress, which includes a branch representing America, has set the following dates:

Paris (Grand Palais)	October 15
London (Olympia)	November
Brussels	December
New York	January
Chicago	February

—

Air Director's Authority and Functions Defined

WASHINGTON, March 24—To enable Maj. Gen. C. T. Menoher, director of the Air Service, to exercise the necessary supervision, control and direction over the Bureau fo Aircraft Production and the Division of Military Aeronautics, with which he is charged by the Secretary of War, the following was announced by the Chief of Staff:

The Director of Air Service will carry out the duties of the Chief of the Air Service, as prescribed in Article LXXXI, Army Regulations, 1913. He will exercise, under the direction of the Chief of Staff, full and complete supervision, control and direction over the Bureau of Aircraft Production and the Division of Military Aeronautics, in all that pertains to administration, supply, instruction, training and discipline.

General Orders, No. 80, War Department, 1918, have been amended by striking out the words, "the Directors of Military Aeronautics, of Aircraft Production," and substituting the words, "the Director of Air Service."

Germany Increases Automobile Output

Many Companies Add to Their Capital — Dividends Also Enhanced, Some 16%

WASHINGTON, March 24—The difficulties of wartimes have affected the German automobile industry but very slightly, according to a report received here by the Department of Commerce. Nearly all companies have greatly increased their production and their equipment. The typical factor in this industry has been that during the war, owing to the excess of demand over supply, the manufacturers have not been concerned with the finding of markets, as a result of which production has been intensive.

A measure of the increase of motor producing capacity during the war is clearly illustrated by the figures given in the German press of the increase of capital of companies concerned in that production. Thus the Daimler and Bayersche Motorwerke A-G. during the past two years have increased their capitalization by 15,000,000 marks. A considerable increase in the working capital is also noticed, as for example Nationale Automobile Gesellschaft and Hansa Lloyd, the latter increasing its capitalization from 4,400,000 to 20,000,000 marks. The pre-war value of a mark was 24 cents.

The unprecedented flow of money into this industry is remarked on by the German press as not found in other industrial lines and this condition has attracted the attention of the German government, arousing it to oppose any plans looking to a further increase in the capital of these stock companies.

Parallel with the growth of working capital and the increase in the scale of production, there is also a considerable increase in the dividend. Companies which before the war made no profit are now making as much as 16 per cent net. The German press considers that the industry has opportunity for large development after the war.

—

U. S. May Trade with Germany and German Colonies

WASHINGTON, March 22—The War Trade Board will now issue licenses for the importation of ferromanganese from all countries where it has been shown by conclusive evidence that such ferromanganese was contracted for by American consumers prior to April 6, 1917.

It is now permissible for persons in the United States to trade and communicate with persons residing in the colonies owned or controlled by Germany on August 1, 1914, subject to the rules and regulations of the War Trade Board. Individual import licenses will be required for importations into the United States from such territory, and individual export licenses for exports to such territory. No official advices have been received as to what the import regulations in this territory will be, if any.

—

England-Belgium Air Freight Service Planned

WASHINGTON, March 24—An aerial freight service is contemplated between Folkestone, England, and Ghent, Belgium. English manufacturers have been finding it next to impossible to ship goods to Belgium by ordinary transport, owing to the congestion of the docks in that country, and the Aircraft Transport & Travel Co. was quick to realize the opportunity thus offered to demonstrate the possibilities of aircraft for commercial purposes. The company has entered into negotiations with British manufacturers interested in the forwarding of goods to Belgium by air.

The governments of Great Britain and Belgium have been approached in the matter, and the Belgian government has already issued the special certificates necessary for this form of transport. The British Air Ministry has given its consent also to the main scheme proposed by the Aircraft Transport & Travel Co., but stipulates that pilots of the Royal Air Force shall undertake all the aerial trips made.

The load carried will be about 2 tons of foodstuffs, clothing and other necessities. The extension of this service to Antwerp and Brussels is planned.

—

Canadian Municipalities May Impose License Fee

QUEBEC, March 24—Power to impose a tax or license fee on owners of motor vehicles used to carry on the business of cabman or common carrier is given to municipalities in a bill which Hon. Walter Mitchell, provincial treasurer, has introduced in the Legislative Assembly. When a man in the cartage business gave up horses and bought a truck to transport materials, he paid a tax to the Provincial Government under the Motor Vehicle act, but nothing to the municipality. Thus the municipality lost the revenue it had obtained from him when he had used horses.

The municipalities are also given power to make by-laws for the locating of cab stands and to put into force a tariff of fares which may be charged by motor and other vehicles.

—

Mechanics' License Bill to Be Pushed Next Session

TOPEKA, KAN., March 22—The Kansas law regarding the licensing of mechanics has been killed in committee, and those actively engaged in disposing of this pernicious legislation were warned that two years hence this bill would be again proposed, with the further warning that they were going to put it across.

The labor unions are very actively engaged in trying to have this proposed bill made a law, and the president of the Kansas Automobile Trade Association was given to understand that a real fight would be made two years hence, at the next session of the legislature.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Gillette Rubber Sales $1,810,000

EAU CLAIRE, WIS., March 22—The Gillette Rubber Co. expects to reach a daily production of 1000 tires and 2000 inner tubes within a short time, according to the annual report of President S. P. Woodard, New York, at the annual meeting.

Sales in 1918 amounted to $1,810,000, compared with $455,000 for the eight months of actual production in 1917, the first year the new plant was operated. January sales this year were $197,557, compared with $72,520 in 1918; February, $260,000, compared with $108,421 in the same month last year. The production of 1918 was 91,000 pneumatic casings and 77,500 inner tubes.

Western Carburator Reorganizes

ALMA, MICH., March 21—The Western Carburator Co. is being reorganized and will resume operations soon. The capital stock of the company, which is $120,000, will not be increased for the present. Henry Prescott is superintendent and sales manager for the company.

Emerson-Brantingham Expands

ROCKFORD, ILL., March 20—In 1918 the Emerson-Brantingham Implement Co. bought from the International Harvester Co. the Osborne line of harvesting machinery, consisting of grain and corn binders, reapers, mowers and hay rakes. The manufacture will continue at Auburn, N. Y., until some time this summer, when it will be moved to this city. The company has opened an office at 66 Broadway, New York, for export trade.

Prudden Wheel on 100 Per Cent Peace Basis

LANSING, March 22—The Prudden Wheel Co. is back to 100 per cent peace production, having been operating at the time the armistice was signed on 100 per cent war work basis. The company's production is back to normal, requiring the services of 1110 employees. About $60,000 worth of special machinery used in the manufacture of government war products has been returned to the Ordnance Department. The company has $750,000 invested in canceled war contracts, but a settlement with the government has practically been reached.

Canadian Studebaker Plans 50 Daily

WINDSOR, ONT., March 21—The Canadian plant of the Studebaker Corp. is now turning out 15 machines daily, but this production will shortly be run up to the 50 mark. This plant assembles the car only from parts received from Detroit and Canadian parts makers. About 50 per cent of the material is manufactured by Canadian concerns.

Canadian Ford Making 100 Cars Daily

WINDSOR, ONT., March 21—The Ford Motor Car Co. of Canada, Ltd., is now producing 100 cars daily and anticipates greatly increasing her output within the next month.

$5,000,000 Auto Sales Co. Organized

DETROIT, March 22—The Federal Motor Finance Corp. has been incorporated here with $5,000,000 capital to finance dealers in the sale of cars, trucks and tractors. The organization will be national in scope, but will have its home offices here. Branches will be established in all parts of the country. Its directorates, the personnel of which will be made public in a few days, include bankers and automobile men.

Michigan Stamping Co. Earns $501,062

DETROIT, March 22—Net earnings of the Michigan Stamping Co. for 1918 were $501,062, of which $331,062 was credited to profit and loss, and $170,000 paid out in dividends. Sales for the year totaled $3,767,784.54. Assets are placed at $2,517,907.83.

New Tractor Works for Allis-Chalmers

MILWAUKEE, March 24—The new tractor works which the Allis-Chalmers Mfg. Co. is erecting and equipping in connection with its main works at West Allis, a suburb of Milwaukee, will be three stories, 110 x 325. It is expected to be ready in about thirty days, when the tractor department will be moved there from its Reliance works on Clinton Street. The output will be more than trebled. The Allis-Chalmers tractor is now being produced in three types.

Commerce Building

DETROIT, March 24—Plans have been approved for the new addition to the plant of the Commerce Motor Car Co. With this building the company will have 100,000 sq. ft. of floor space. The addition will be of brick and steel and will have 285 ft. frontage on Mackie Street.

New Cleveland in Production July 1

CLEVELAND, March 21—The new plant of the Cleveland Automobile Co., recently organized by Chandler Motor Car Co. officials to produce a $1,300 motor car, will cover approximately 200,000 sq. ft. of floor space, and will cost $650,000. The plant will be completed and the company in operation by July 1. The site of the new factory has not been definitely decided upon.

Acason Making 80 Trucks Weekly

DETROIT, March 22—The Acason Truck Co., since completing war contract work a few weeks ago, has tripled production and is now turning out 80 trucks of all models a week. From now on this company hopes to increase production until full capacity is maintained.

First Annual Report of Oak Tire & Rubber

TORONTO, ONT., March 21—The annual statement of the Oak Tire & Rubber Co., Ltd., for its first year of operation, 1918, revealed net profits of $32,735. At the close of the year its total assets were $462,178. Out of the net profits $14,500 has been set aside as reserve.

The following directors were appointed at the annual meeting: Frank Law, Toronto; T. E. Finlay, Norwood; J. H. L. Patterson, Toronto; A. E. Willar, Galt, and William Seward, Baltimore, Md.

Oneida Truck Co. Increases Capital and Changes Personnel

GREEN BAY, March 24—The Oneida Motor Truck Co. has increased its capital stock from $300,000 to $600,000 as the forerunner of a general expansion plan which will probably make necessary the erection of additions to the plant built about two and a half years ago. At the annual meeting Lafayette Markle, for several years president and general manager of the Republic Motor Truck Co., Alma, was elected president and general manager of the Oneida company.

Dividends Declared

The McGraw Tire & Rubber Co., East Palestine, O., quarterly dividend, 3 per cent on common stock, paid March 1.

Flower Valve Mfg. Co. to Add

DETROIT, March 22—The Flower Valve Mfg. Co., formerly the Flower-Stephens Mfg. Co., has completed the sale of $450,000 7-per cent first mortgage serial bonds to local bankers. The company's plant covers 6½ acres, employing over 400 men, and with its additions the number of employees will be largely increased. This company made propeller wheels and ship sets for the Emergency Fleet during the war in addition to its regular business.

Nash Production Reaches 100 Car Mark

KENOSHA, WIS., March 22—The Nash Motors Corp. has completed its contract which called for 1600 Quad trucks for the Government and is otherwise winding up its war work. The company is now devoting 90 per cent of its attention to the manufacture of its regular car production. In February this company produced 65 cars daily. In March production will be increased to 90 cars, while the 100 machine mark will be reached early in April.

Automatic Products for 500,000 Cars

DETROIT, March 24—The Automatic Products Co. will this year devote its entire capacity to the automobile industry, and has completed a production schedule which calls for the manufacture of its parts for 500,000 cars. During 1918 over 65,000,000 pieces were produced, a large percentage of which were used in the assembly of airplanes.

Detroit Truck Makers Use Pneumatics

Discernible Tendency Toward Use of Cord Tires for 1½- and 2-Ton Vehicles

DETROIT, March 21—The pneumatic cord tire is being adopted by Detroit truck makers as standard equipment on 1½- and 2-ton trucks. For some time the pneumatic tire has been standardized on lighter models, but a tendency is now prevalent to increase the use of pneumatics in the heavier truck field. While no truck makers have gone so far as to equip 2-, 2½- and 3-ton machines with pneumatic tires as standard, they are turning out a large number of such jobs, pneumatics having been requested by purchasers. Every local truck company is feeling an increasing demand for pneumatic tires instead of the solid variety.

Sales engineers declare the day of the pneumatic tire is coming and that the next year will see it standardized on all jobs up to 2½ and 3 tons by the majority of the big manufacturers.

Practically every tire company in the country has been working on pneumatic cord tires. The last 60 days have brought the sales engineers of all of the big Akron plants to Detroit. The companies have launched extensive advertising campaigns urging the more extended use of the cord product, and it is now apparent that their sales and publicity enterprises are beginning to bear fruit. They are overcoming the one big objection to cord tires—the greatly increased initial tire cost.

This objection has been raised by both the truck maker and the owner, but it is being beaten down at both ends by the sheer mass of statistics compiled in favor of pneumatics. The tiremakers are successfully pointing out many advantages, chief of which is a longer life of both tires and trucks obtained by the use of pneumatics.

All new 1½-ton trucks of the Commerce Motor Car Co. have 36 x 6 pneumatic cord tires as standard equipment. The Acason Motor Truck Co. is about to bring out a new 1½-ton model similarly equipped. Packard, Wilson, Federal, Republic and others are seriously considering the pneumatic tire and are placing it on their lighter machines when desired by purchasers. It is not unusual here in Detroit to see a factory experimental truck with four pneumatic tires, all of different make, and the company whose new cord product best withstands these road tests is the one going to get the tire business of the manufacturer.

The Commerce Motor Car Co. is pushing pneumatic equipment. Both Commerce, Acason and other engineering authorities declare they cut vibration and relieve road-strain to such an extent that the load capacity can be increased 50 per cent. This company is advancing this as an unusual selling feature. Its engineers advocate overloading if the tire equipment is pneumatic. This company has numerous 1½-ton machines which are carrying 2 tons.

From the manufacturing standpoint, the builders find that machines equipped with pneumatic tires may be built of much lighter units inasmuch as the jar and strain, which the solid tire truck must be built to withstand, is largely eliminated.

In 1911 the Commerce people and a number of other companies produced pneumatic tire jobs. The Commerce product was a ¾-ton machine weighing 2000 lb. At that time pneumatic tires were an uncertain proposition, and they soon gave way to the hard-rubber type. In order to use the hard rubber tires, however, this company found it necessary to practically rebuild the truck on much stronger lines. Every important unit, springs, axles, etc., had to be built much sturdier. When this job, with hard rubber tires, was ready for the road, it weighed 2950 lb.

The government was the first to realize the value of the cord pneumatic tire on the larger size trucks, and specified that its 1½-ton war truck be equipped with 36 x 6 pneumatics. While use of these tires increased the truck cost, the government found that by using them the trucks could get more capacity, withstand greater hardship, save on oil and gasoline and had many other advantages which offset the extra tire expense.

—

Accessories Branch of National Hardware Assn. Meets

DETROIT, March 21—The annual meeting of the Automobile Accessories Branch of the National Hardware Association, which closed Friday night, was more of a convention of accessory manufacturers than it was of accessory jobbers. Over three hundred members were present when the gathering convened at Hotel Statler, and of this number the great majority represented factory organizations.

In connection with the convention proper, the first annual accessory show was held. This show will be a regular feature hereafter, although the question has arisen as to the advisability of staging it in connection with the annual meeting. The chief objection of holding the two events at the same time lies in the fact that the show had a tendency to keep the interest of the members from centering entirely upon the convention.

The two days of the meeting were crammed full of addresses and discussions.

The manufacturers centered their effort in convincing the hardware men that the hardware store was the logical place to handle accessories, just as logical as the garage or automobile shop, and they went the limit in urging the dealers to not only hanlle accessories, but to push their sale to a greater degree than they have been doing.

On the price question the convention took a definite stand against the "price cutter," and as a result the man who "undersells" the market is going to find it harder going in the future than in the past.

$14,000,000 In Orders Uncompleted

Few War Contracts for Tanks, Tractors and Trailers Now Being Finished

WASHINGTON, March 22—War orders for $14,929,502 worth of tanks, tractors and trailers still remain to be completed for the army. This includes:

392 6-ton tanks at $4,508,000, needed to give a working stock.

628 10-ton tractors at $4,082,000, not needed, but can be used.

450 2½-ton tractors at $1,561,950, needed to motorize 75 mm. guns.

216 20-ton tractors at $1,521,720, needed.

100 30-ton tanks at $500,000, needed as a working stock.

262 5-ton tractors at $1,181,620, needed to motorize reserve artillery.

108 3 in. gun auto-trailers at $575,000, needed for guns already completed.

In some few instances orders are being completed because there is no termination clause in the contracts, but in most cases, as will be seen above, there is still a need for some numbers of tractors, trailers and tanks.

All 5-ton and 10-ton tractors now in France are reported in use and spare parts and tops are being shipped overseas in quantities. Experimental work is being done with the 2½-ton tractor to make it suitable for motorizing the 75 mm. gun regiments.

Following is the total number of tractors that have been delivered or will be delivered on contracts:

Tractors:

2½-ton	1,000
5-ton	4,000
10-ton	2,800
15-ton	267
20-ton	400

Tanks:

3-ton	15
6-ton	950
30-ton	100

Status of Contracts Outstanding Nov. 11.

Tractors	Canceled or ordered suspended	Delivered Nov. 11 Feb. 27	Remaining Feb. 27
30-ton (tank)	2,850	0	100
2½-ton	5,079	45	450
6-ton (tank)	3 490	436	392
5-ton	7,150	2,269	262
20-ton	765	59	216
10-ton	3,823	793	628

—

Pennsylvania Plans Huge Road Outlay

HARRISBURG, March 24—Plans are now completed, and some of the contracts have already been let, for the greatest program of road building and maintenance in the history of the State. Within the next 4 years a total of $130,000,000 will be spent for road work, and for the balance of this year alone more money will be spent than was spent in the last eight years. A bond issue of $60,000,000 has been passed by the legislature, $6,000,000 is available from state aid and $12,600,000 from other sources.

During the present year it is planned to build 3500 miles of primary road system, paid for by the State. All primary roads are to be constructed along perma-

nent lines, and will be built with concrete foundations. All new roads are to be built by the contract system, and some 234 companies have been bidding. After the roads are completed they will be taken over by the state and the state highways department will keep them in order. For this purpose 23 tractors, which were used last year to help farmers open up new grounds, have been transferred from the Department of Agriculture to the Department of Highways, and these will be used to drag the existing roads and keep them in shape.

There are approximately 90,000 miles of roads in Pennsylvania. The state is bearing the entire cost of extending the primary system. The counties are expected to raise the money to build and maintain the secondary routes or feeders.

—

Millions for Central West Roads

WASHINGTON, March 22—Additional details of highway construction received here indicate that the entire nation is awake to highway value.

Colorado has 51 miles of highways under construction at a cost of $300,000; 91 miles ready for contract to cost $360,000; and 30 miles and 3 bridges contemplated, to cost $350,000. Maintenance on 4000 miles will amount to about $500,000, while local road and bridge expenditure will amount to about $2,200,000.

Idaho has 87 miles, costing $720,000, under contract; 45 bridges, costing $425,000, ready for contract; and about $1,800,000 worth of additional work is contemplated during the season.

Iowa will expend $15,000,000 on the road system of the state, of which about $11,000,000 will be for road and bridge construction.

Missouri has 666 miles under contract, costing $1,785,100; 888 miles, costing $3,104,000 ready for contract; and about $3,000,000 additional construction is contemplated. Local road and bridge expenditures in the state will amount to about $7,000,000.

Nebraska has 173 miles, costing $431,000, under contract; 145 miles, costing $550,000, ready for contract; and about 610 miles, estimated at $1,310,000, contemplated. Local road and bridge expenditures will amount to about $3,000,000.

Nevada has 4 miles, costing $54,666, under contract; 102 miles, costing $657,412, ready for contract; 123 miles, costing $523,000, contemplated. Local expenditures on maintenance will amount to $600,000.

Oklahoma has 178 miles, including 80 bridges, costing $1,360,000, under contract. Additional construction of 165 miles, costing $2,500,000, is contemplated. Local road and bridge work will amount to about $2,200,000.

These amounts will be supplemented by increased Federal Aid appropriations and later, it is hoped, by national construction of main trunk lines under the supervision of a Federal Highway Commission, as provided in the Townsend bill, which will come up for consideration by the next congress.

Expect British Trade to Be Free

Detroit Makers Still Await Official Confirmation of Lifting of Import Embargo

DETROIT, March 21—Counteracting the stimulus given Canadian manufacture of Detroit automobiles by the reported lifting of the British embargo on Canadian made automotive products is a prevailing belief here that Great Britain will very shortly lift her embargo against United States products, thus opening the British empire to American automotive export trade. Not a word of information regarding Great Britain's action concerning the Canadian embargo has reached this city from either Washington or London, and customs officials at Windsor, Ont., have received no official word of such a ruling.

J. A. Smith, Collector of Customs at Windsor, has taken the matter up with Canadian officials at Ottawa, however, in behalf of a number of American car makers as well as Canadian parts concerns located in the border cities.

He declares regulations are changed so frequently that it is difficult to give out definite information. He is of the belief, however, that Britain is not making any distinction whether a car is manufactured or merely assembled complete in the Dominion and thinks that an assembled car, even if assembled from American-made parts, is a Canadian product. There is a 33 1/3 per cent duty on goods manufactured in the United States.

There is no question but what American manufacturers are going after British Empire trade through the expansion of Canadian manufacturing plants, but expansion plans are being held up on the belief that the embargo against the United States will soon be lifted.

The demand of the British trade for cars, a demand already greater than Britain can possibly supply, is going tc be the big factor in expected action which will permit American cars to go to England duty free, the manufacturers here declare. They point to the fact that British plants have been on a war work basis for 4 years and it will be some time before they can resume their commercial work again. The British people are buying low priced machines and that country cannot possibly produce enough such cars this year to meet requirements without import aid from the United States.

About the only information relative to Britain's embargo action comes from Ottawa, where the War Trade Commission has received two cables from the Canadian Mission in London. The first reads:

"Effect has now been given to Government decision to allow importation of Empire goods by issue of open license allowing import of all goods from British Empire, except gold and articles containing gold, unless consigned to Bank of England, spirits other than brandy or rum."

The second is:

"British Board of Trade regulations will insist only goods of Empire origin free from import restriction. Making definite announcement and asking government to provide necessary machinery to prevent foreign manufactured goods reaching England through Canada."

In the first it appears that it will only be necessary for the British agents of Canadian automobile manufacturers to apply for the necessary open license. Obviously, the policy as outlined in these cables, if adhered to or even if modified simply to an Imperial preferential tariff, will result in practically all the large American automotive manufacturers establishing plants in Canada, as it is clearly indicated that they must at least do this if they desire to compete on even terms with the automotive manufacturers who now have plants in the Dominion.

However, the tariff situation generally in so far as Canada is concerned is far from stable. The farmers, especially the western grain growers, are demanding a radical downward revision of the existing tariff. The present political split in eastern Canada practically gives the west the balance of power and consequently the demand of the western grain growers carry considerable weight. On the other hand, almost without exception, the western members of the government, while advocating downward revision of the tariff, are unanimous in declaring allegiance to the Union government.

The chief demands of the western grain growers are:

An immediate and substantial all-round reduction of the Custom's tariff.

Complete free trade between Great Britain and Canada in five years.

The acceptance of the reciprocity treaty with the United States which was rejected by Canada in 1911.

That any further reduction of the tariff of the United States towards Canada be met by a similar reduction of the Canadian tariff towards the United States. (That is free trade with the United States at any time the United States is ready for it).

Obviously, this program is heading directly for free trade between Canada and other countries and the manufacturers are vigorously opposing it in Parliament on the platform and in the newspapers. They contend that free trade or any approximation to it for Canada would immediately result in making the Dominion a dumping ground for the world, thus sounding the death knell of Canadian industry, with the consequent unemployment and depression.

—

No Discussion at Buffalo S. A. E. Meeting

BUFFALO, N. Y., March 21—The future use of airplanes was the subject of a meeting of the Buffalo Section of the Society of Automotive Engineers held here last evening. The speaker was Douglas Wardrop, who spent practically all of last summer near the western front.

That a regular airplane transatlantic schedule would be in operation before the end of this year was predicted by the speaker, who bases his conclusions on the proposed flights of the United States Navy, the British flying boat en route to Nova Scotia and a large Caproni developed for the same purpose.

No discussion developed at the meeting, although in view of the attendance of C. M. Manly, president of the S.A.E., and one of America's foremost airplane pioneers; David Fergusson, chief engineer of Pierce-Arrow; E. T. Larkin, chief engineer of the Sterling Engine Co., and other prominent engineers, it was confidently expected that some interesting discussion would develop along engineering lines. Mr. Manly occupied the chair and adjourned the meeting immediately after Mr. Wardrop had finished his lecture.

The meeting was held under the auspices of the Buffalo engineering Society, which is a joint organization of the local sections of the large national engineering societies. About 100 were in attendance.

Foreign Exchange and Trade Restrictions Modified

WASHINGTON, March 22—Restrictions placed on foreign trade affecting foreign exchange transactions and financial and commercial cables have been modified by the Federal Reserve Board. Dealers in foreign exchange can now transfer funds to persons who are not enemies or allies to enemies in Roumania, Serbia, Syria, Mesopotamia, Finland, Bulgaria, Turkey in Asia and in Europe and all the Black Sea ports.

Foreign exchange dealers in the future need not secure approval for issuing travelers' letters of credit in excess of $5000. Great Britain, Canada and France are acting coincidentally with the United States in the measures outlined. Until further notice the exportation or importation of Russian rubles for the transfer of funds for their purchase by persons or dealers in the United States is prohibited.

Spain Supervises Gasoline

WASHINGTON, March 24—The restrictions on the sale of gasoline and the substitutes, known as A. N. C. No. 2 and A. N. No. 1, manufactured by petroleum refiners in Spain, have been removed by a royal decree published Dec. 14, 1918, special permits being no longer required.

Gasoline and the substitutes mentioned will be sold at prices fixed or to be fixed by the Ministry of Supplies, which will dictate measures for the distribution of gasoline, the monthly quantities which may be put on sale by the refiners, and will exercise all necessary vigilance in regard to consumption, inspection and supplies to the different provinces.

A royal order published on the same date provides that petroleum refiners must submit to the Ministry of Supplies on the 1st and 15th of each month a statistical statement covering crude petroleum, gasoline and derivatives manufactured; that the refineries arrange their depots in all the provinces; that all merchants registered under the industrial tax may sell gasoline and the substitutes A. N. C. No. 2 and A. N. No. 1; that the sale of these substitutes is authorized by the refiners of petroleum, giving preference to public utilities, and that the maximum selling price at the factory be fixed.

The refiners are authorized to put on sale any quantities of A. N. C. No. 2 and A. N. No. 1 up to 1,000,000 liters.

Tin Importers Association Protests

NEW YORK, March 24—The Tin Importers Assn. has enlisted the cooperation of the National Association of Purchasing Agents to remove the restrictions on the sale and price of tin. The latter association has a membership of 1800 industrial purchasing agents, a large percentage of whom are direct buyers of tin. The basis of the complaint of the tin importers is that pig tin can be purchased abroad at 25 cents per pound cheaper than here.

Calendar

ENGINEERING

April 2—Minneapolis Section, S. A. E. — Hotel Radisson. "Implements Designed for Tractor Belt Power and Their Characteristics."

SHOWS

March 22-29—Pittsburgh Automobile Dealers' Assn. of Pittsburgh. John J. Bell, Manager.

March 24-29—Greenfield, Mass. Greenfield Automobile Dealers' Assn., State Armory. James J. Callahan (Pittsfield) Manager.

March 24-29—Utica, N. Y. Utica Motor Dealers' Assn.

March 25-29—Wilmington, Del. Fourth Annual, Wilmington Rink.

March 26-27 — Clinton, Ia. Fourth Annual Clinton County Automobile Dealers' Assn.

March 26-29—Watertown, N. Y. Tenth Annual, State Armory, Automobile Dealers, Inc. Arthur E. Sherwood, Manager.

March 27-29—Holdredge, Neb. Third Annual, Holdredge Automobile Dealers' Assn.

March 28-30—Peru, Ill. Illinois Valley Auto Show.

Last of March — Harlan, Ia. Southwestern Iowa Motor Exhibit.

March 29-April 5 — Passenger Cars. April 8-12—Trucks, Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I. C. Kirkman, Manager.

March 31-April 5—Cumberland, Md., Automobile Dealers Assn., Armory.

March 31-Apr. 5—New Orleans, La. Henry B. Marks, Manager.

April 1-5—Denver, Col.—Denver Automobile Trades Assn. Stadium.

April 3 — Macon, Ga. Motor Truck Demonstration, Macon Automobile Chamber of Commerce.

April 5-12 — Bridgeton, N. J. Fourth Annual, Automobile Dealers' Assn.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

April 8-12—Deadwood, S. D. Seventh Annual, Cars and Tractors, Deadwood Business Club.

April 16-19 — Waynesburg, Pa. Automobile Dealers' Assn. of Greene Co., Armory. Frank L. Hoover, Mgr.

April—Little Rock, Ark. Second Annual, Little Rock Automobile Dealers' Assn., Liberty Hall.

May 10-17—Bristol, Va.-Tenn. Cars, Trucks, Tractors, Airplanes and accessories. Bristol Chamber of Commerce. C. W. Roberts, Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

*Oct. 15—Paris. Grand Palais, International Automobile Mfrs. Congress.

November—London — Olympia—International Automobile Mfrs. Congress.

TRACTOR SHOWS

April 15—Walla Walla, Wash. Sectional Tractor Demonstrations.

May 5—Sacramento, Cal. Sectional Tractor Demonstrations, Demonstration Field.

June — Denver, Col. Sectional Tractor Demonstrations.

July—Wichita, Kan., Automotive Committee of National Implement Assn.

Aug.—Aberdeen, S. D. Sectional Tractor Demonstrations.

RACES

†May 17—Uniontown, Pa., probably 112½ miles.

†May 31—Indianapolis, Indianapolis Motor Speedway Assn., 500 miles.

*July 5—Cincinnati, O., Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 22-23—Elgin, Ill. Speedway.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Oct. 1—Cincinnati, O. Speedway race.

†Sanctioned.
*Tentative dates.

CONVENTIONS

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

May 1-June 1 — Atlantic City, N. J.—Pan-American Aeronautic Convention and Exhibition — Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

New Dart Officers

WATERLOO, IA., March 24—C. C. Wolf was elected president of the Dart Truck & Tractor Corp. at its annual meeting. Other officers elected were vice-president and general manager, W. H. Johnson, formerly chief engineer; vice-president and sales director, M. D. Herron; secretary and treasurer, E. L. Stover. H. H. Henry, the retiring president, has accepted the vice-presidency of the Maxim Munitions Corp., the Atlantic seaboard and export distributers of the Dart line.

Wichita Motor Co. Officers Elected

WICHITA FALLS, TEX., March 24—At the annual meeting of the stockholders and directors of the Wichita Falls Motor Co., J. A. Kemp, who has been president of the company since its organization, was elected chairman of the board of directors. J. G. Culbertson, who has been secretary, treasurer and general manager, was elected president and re-elected treasurer. A. G. Savelli was re-elected vice-president in charge of export and G. S. Brenemann, secretary. Two new buildings have recently been completed.

Youngstown Tube Re-elects Directors

YOUNGSTOWN, OHIO, March 24—All directors of the Youngstown Sheet & Tube Co. were re-elected. The annual report showed total earnings of $25,925,118 and net products profit of $14,589,488 after charges of depreciation, adjustment of inventories and in cost of construction for war purposes. The net surplus profits after dividends was $10,194,767. During the year the company paid $22,157,000 in wages against $16,396,000 in 1917, while sales decreased $5,000,000 from the previous year because of reduced tonnage and government price control. The company has inaugurated a plan of co-operation of employees in the settlement of labor differences.

American Bronze Corp. Elects New Officers

BERWYN, PA., March 24—At the annual meeting of the Board of Directors of the American Bronze Corp. the following officers were elected: President, Harry Porter; vice-president, general manager and treasurer, Mathew Dittmann; secretary and sales manager, Edward Anderson.

Northway Motors Starts Production

NATICK, MASS., March 24—The Northway Motors Corp. has the first series of its buildings completed and the machinery installed. They are one-story structures. Foundations for other buildings have been commenced.

Work has been begun on trucks and cars. The machines will have four-cylinder engines. The company has floated a $1,000,000 stock issue to begin business.

Denby Buys Wolverine Brass Plant

CHATHAM, ONT., March 24—The Denby Motor Truck Co. has purchased the factory of the Wolverine Brass Co.

Carlisle Cord Tires on Peace Basis

NEW YORK, March 21—At the annual meeting of the Carlisle Cord Tire Co., the following officers were elected for the year: President, J. S. Bretz; vice-president, C. A. Gilbert; treasurer, Lewis H. Homer; secretary, F. R. Serles; assistant secretary and treasurer, C. V. Tuthill.

Since the company has been relieved from war contracts its factory has been working continuously to make up on production.

Hayton Co. Takes Over Killen-Strait Tractor Plant

APPLETON, March 22—The plant of the defunct Killen-Strait Tractor Co., recently sold at receiver's auction, has been taken over by the Hayton Pump & Blower Co., incorporated, with a capital stock of $50,000, to manufacture centrifugal pumps, blower systems, etc. T. R. Hayton is president and general manager. E. D. Rasmussen, for twenty years connected with the pumping engine department of Allis-Chalmers Mfg. Co., Milwaukee, is secretary and general superintendent.

Miller Rubber Officers

AKRON, March 22—The new officers of the Miller Rubber & Tire Co. elected for the year, are: President, Jacob Pfeiffer; secretary and treasurer, W. F. Pfeiffer. J. M. Doran, C. T. Grant and F. B. Theiss, together with the officers, form the board of directors.

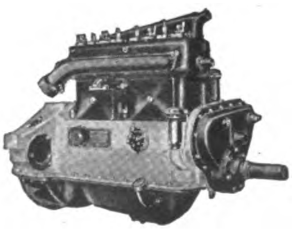
America's Standard Passenger Car Motor. Look for the Red Seal Nameplate.



America's Standard Truck Motor. Look for the Red Seal Nameplate.

His Strongest Selling Point is the Red Seal Continental Motor

The argument that most often clinches the sale of an automobile or truck is the Red Seal Continental Motor.

For there is hardly a man who is not familiar with the record of *past performance*—the infallible test of motor worth—which has distinguished this motor for well over a decade.

On hundreds of thousands of automobiles and trucks, under every conceivable condition of service, the Red Seal Continental Motor has *proved* its 100% dependability. In the supertasks of war, in the vigorous tasks of peace, it has stood the test of service.

Today upwards of 15,000 dealers have signified their belief in the Red Seal Continental Motor by entrusting their business prosperity to Continental-equipped cars. And their choice is the Continental because of its proved record for power, for speed, for economy, for reliability.

Today more than 160 successful manufacturers of automobiles and trucks equip their output with Red Seal Continental Motors. The judgment of these manufacturers is vindicated by tens of thousands of owners who will have no other motor.

Look for the Red Seal on the motor in the car or truck you buy—and *be sure.*

America Influences Europe's New Cars

Left-Hand Steering Is Here—Two-Unit Electric Units Popular—Vacuum Fuel Feed Adopted—Many Double Rear Wheel Brakes—Quieter Colors—New Berliet, Peugeot, Fiats and Others at Lyons Trade Fair

By W. F. Bradley*

LYONS, FRANCE, March 10—The trade fair which is being held here unites 4700 exhibitors with $4,000,000 worth of goods, and has become so big that it has been decided to split it into two parts, one to be held in the spring and the other in the fall. The automobile section, which has its own special building in the fair, will be included in the spring meeting.

The automobile section this year is just sufficiently big and important to give an indication of what is going to happen in France during the next 6 months. An interval of rather less than 4 months has elapsed since the signing of the armistice, this being too short a time to allow more than a few makers to get out new models. But while the majority of the cars are pre-war types, with the addition of electric lighting and starting, there is quite enough revealed or announced to allow an accurate summary to be formed of coming activities.

*Editor's Note—Mr. Bradley attended the Lyons Fair for the exclusive service of the Class Journal Company. Previous to the opening of the show he visited many of the French factories.

Entirely new cars have been built by Delage, Berliet, Fiat, A.S.S., Peugeot, Rochet-Schneider, Citroen and Sigma. All the others are intermediate models.

European Ford Wanted

While the number of entirely new cars on exhibition is small, plenty of information was available at Lyons regarding the immediate program of automobile concerns and on the general tendency of design. There is undoubtedly a great demand in France for what may be termed a European Ford; this is a car as near as possible to the Ford price, carrying four passengers comfortably, but having a better appearance and a lower gas consumption than the Ford. Up to the present there is no such car on the market, nor clearly in view.

The tendency has been toward a very small, light car, of the Citroen type, which is very satisfactory as a two-seater, but not so suitable with a four-seater body. It looks as if the new Peugeot will get very near this class, for one of the Peugeot factories will be given over en-

The new four-cylinder, four-passenger Peugeot which has been designed for quantity production. It has a unit power plant, is equipped with electric lighting and starting system and is driven from the right side

tirely to the production of this car, and it is evident that the design has been worked out with a view to low production costs.

France's Assembled Car

A group of ten French automobile manufacturers has been formed to build a joint cheap car. Each factory will build the component for which it is best equipped; a special erecting shop will be established, and the car will be marketed to the benefit of the ten firms concerned. At present it has not been decided what price this car will be sold for, nor what its main characteristics will be. In all probability it will not get as low as the Ford price in America, but it should be possible to sell it at an unheard of price for France. French manufacturers as a whole are not disposed to get down to the grade of production of the cheaper American cars.

Progress in Production

Simplified methods of construction and labor saving devices are coming along fast, but the idea of the rough finish which is associated with all the cheap American lines is distasteful to the French maker. Present prices must not be taken as a criterion, for raw material is still high and even scarce. A very big drop is expected within one year.

Very few factories are going to build a single model. Quite a number, however, will be satisfied with two types, while it is generally accepted that there is no need for any firm to build more than four models.

Peugeot's Quadrilette

In addition to its 10-hp. light car, Peugeot will put on the market a 12-hp. medium, four-cylinder, five-passenger type and a high-class, six-cylinder, valveless seven-passenger car.

An entirely new venture is what is known as a quadrilette, this being a machine intended to take the place of the motorcycle and side-car. It will have a four-cylinder engine and worm drive.

Renault's Fall Model

Next October Renault will put out an entirely new model four-cylinder car of 2.9 by 4.7-in. bore and stroke, with three-speed gear-set, left-hand steering, detachable wood wheels, with tires of 760 by 90 mm., electric lighting and starting. The price of this chassis will be $1,350 complete with everything except lamps.

New Renault Factory

Renault has the biggest automobile factory in France, and the second biggest in Europe, his regular staff being 25,000 workpeople. Recently he has laid plans for the erection of a new factory at Le Mans, 150 miles southwest of Paris, where 5000 workpeople will be employed. Here he will build trucks, agricultural tractors, trailers and some railroad material. A large number of houses are being erected for the workpeople and a big hotel for the unmarried men. There will be three clubs, baths, swimming pool, infants' school, nursery, a medical hall, a theater, picture hall and music kiosk.

Gnome Builds Cars

The Gnome and Rhone aviation motor company has entered the automobile field and will build Piccard-Pictet cars under license in their two factories near Paris. The models to be produced are a 10-hp. and a 14-hp., four cylinders, as well as a 28-hp. eight cylinders. All three models are to be equipped with electric lighting and starting, mechanical tire pump, speed indicator and accessories. It is understood that the size of the eight-cylinder car will be 85 by 130-mm. bore and stroke, and that this model will be fitted with front-wheel brakes. At the Lyons Fair the Piccard-Pictet Company exhibited the Argyll type of single-sleeve-valve engine.

Dietrich Six and Twelve

Lorraine-Dietrich, who has specialized on aviation motors during the war, will produce two six-cylinder cars and one twelve, all being high-class jobs.

General European Trends

THE general tendency of European construction is now very clearly defined. The four cylinder engine is holding its own, but for high-class jobs the six will predominate. Eights will come next in line, with twelves last on the list. Up to the present only one eight has been produced commercially in France, this being the original De Dion Bouton. In addition to the Gnome eight, it is very probable that an eight-cylinder engine will be brought out by Darracq.

Fiat Uses Detachable Heads

Detachable cylinder heads are making their appearance slowly, but will certainly become more popular during the next 12 months. Fiat has been the first to make a

decided move in this direction, by adopting detachable heads for all models, from the cheapest to the most costly. As Fiat has always been very proud of the cleanness of its design and has never made a mechanical change without long preliminary tests, it is certain that this example will be followed.

Battery Ignition Appears

The tendency to drop the magneto and rely on the batteries for ignition is being manifested very slowly. Engineers, particularly those who have an eye to low cost of production, are convinced of its soundness, but the sales organizations are rather afraid of offending the public, which has been educated to believe that the only reliable ignition is by means of high-tension magneto. Nevertheless, some high-class cars to be shown at the Paris Salon next October will be minus a magneto.

L-Head Engine Continues

The L-head type of engine holds its own without any difficulty. Engineers have given attention to the overhead-valve type, but where in favor state that it will not be brought out for 2 years yet.

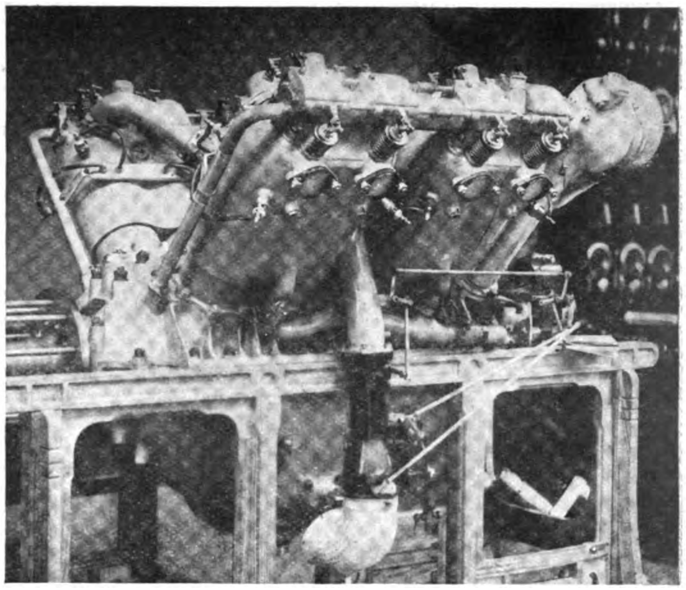
The most popular method of driving the pump and the magneto is by means of a transverse shaft. This is found on all the Fiats, on the new Delage, on the new Cottin-Desgouttes, on the Renault (in this case, of course, there is no pump). The position tends to complete accessibility by putting the business ends of these two organs outwards, where they can be readily reached.

There is nothing to indicate that thermo-syphon is ousting the pump. Where the engine has less than 3-in. bore natural water circulation is in a slight majority, but above this size the water pump is nearly always used, the only important exception being Renault, who refuses to fit a pump whatever the size of the engine or whatever the work it has to perform. The reasons for this are of a personal and not of an engineering nature.

Front Radiators Gain

The practice of placing the radiator back of the engine has lost ground. Th. Schneider and Charron, who before the war had radiators at the rear, have dropped this position for the more conventional one in front. Renault is now practically alone in this style of construction.

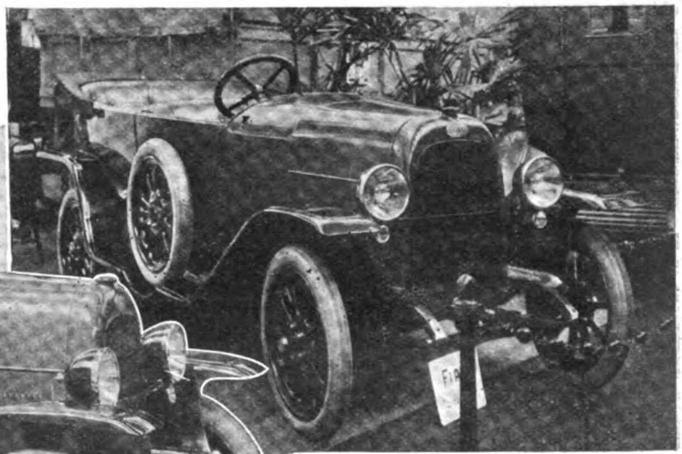
On the new Cottin-Desgouttes engine the transverse shaft drives not only the magneto and water pump at each end, but the fan and a two-cylinder tire pump. This is one of the few cars fitted with a power inflator.

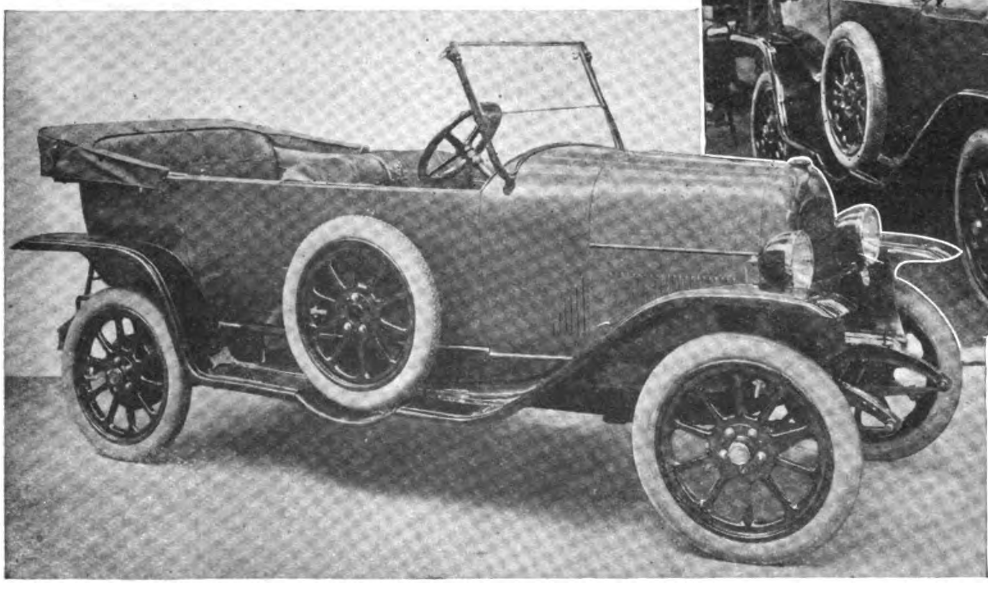


Carbureter side of the eight-cylinder Lorraine-Dietrich aviation engine, showing the overhead valve mechanism

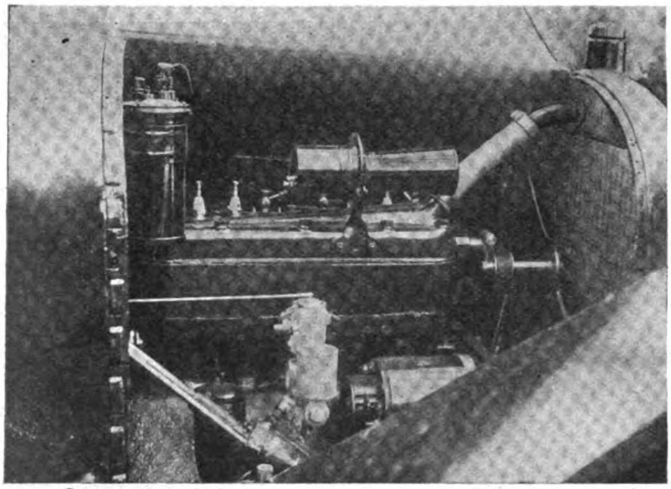
Vacuum Fuel Feed

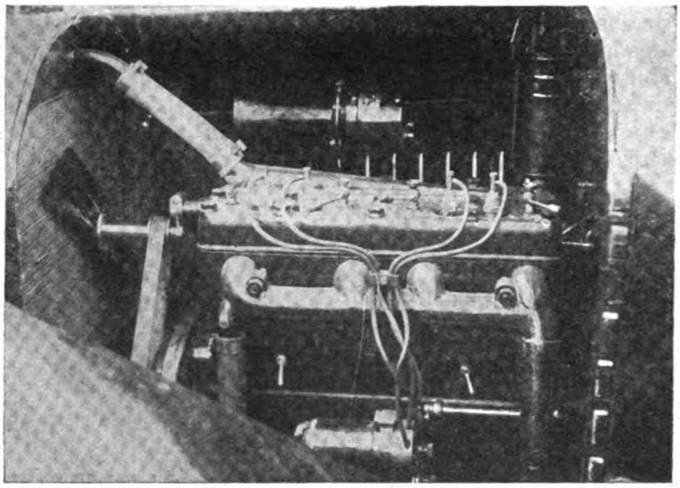
The tendency everywhere is to bolt carbureters direct up to the cylinder casting on the side opposite to the valves and to feed gasoline to the carbureter by the vacuum system. The pressure system has practically gone out of existence, while gravity feed is only being used for small cars where a tank on the dashboard is not of sufficient size to cause any inconvenience. Makers of high-class cars have had two years' experience with the vacuum system, and in their opinion it is most satisfactory, provided the apparatus is individually tested for the car to which it is fitted. They find that as received from the manufacturers the outlet from these appliances vary considerably, and it is necessary to





These are the two new Fiat models, the one at the left being the 12-16-hp. model and the one above the 10-hp. model





Both sides of the new Berliet four-cylinder engine, which in many respects closely follows accepted methods of American design and construction, notably in the use of detachable cylinder head and the mounting of accessories

test them for individual cars to get really satisfactory results.

Forced-feed lubrication with a drilled crankshaft, oil being supplied under pressure to the main bearings, the camshaft bearings and to the connecting-rod ends, other parts being fed by the overflow, is the system most extensively employed. More attention has been paid to the ready removal of filters and pumps, and with this object in view many makers who formerly placed the pump on the end of the camshaft now locate it in the base chamber. As the tendency is to get away from a mud pan, and to fill in the space between the crankcase and the frame members, this adds further to accessibility. Several makers carry a supplementary oil tank in the engine or in the chassis. Hispano-Suiza has done this for a considerable length of time. Cottin-Desgouttes has a 1-gal. supplementary oil tank cast on the side of the crank chamber, and communicating with the base by means of a passage and screw-down needle valve. Chenard-Walcker and La Buire both provide systems of renewing the oil supply without pouring direct into the base chamber.

Unit Powerplant Gains

Unit construction of engine and gearbox is being adopted by practically everybody. Very few makers indeed are casting cylinders and crankcase together; in some cases the reason for not doing this has been the difficulty of getting good castings. The cylinders are thus mounted on an aluminum base chamber, and to this latter is attached the clutch and gearbox housing.

There is no uniformity in the method of attaching this unit to the frame. Some have a four-point attachment for the engine, which therefore tends to stiffen the frame at the front. Others bolt to the side members and to a forward cross member, while a certain number have a true three-point suspension, with rigid attachment to the frame and trunnion attachment to the front cross member.

On the lighter chassis the tendency is to have only three cross-frame members; one at the rear, one at the front, and another at the forward point of attachment of the rear springs.

The only really high-class job which departs from unit construction is the Rochet-Schneider. Here the engine is on a subframe and the gearbox carried on two cross members in the center of the chassis. While the details are well carried out, the feature of this design is quite contrary to the general tendency.

Left-hand steering, with center control, is coming along. Renault is going to adopt it for his new popular model. Citroen has already adopted it. The real objection now is that left-hand steering will not be accepted by English buyers, and as there is little possibility of convincing the English nation of the advisability of changing its singular rule of the road to that of the rest of the world, French firms who count on selling cars in England keep to right-hand steering so as not to have two different types.

Spiral Bevel Strong

The change from bevel and worm to spiral bevel gears is really remarkable in its unanimity. This type of gear is already used, or going to be used, by Fiat, Renault, Panhard, Delage, Darracq, Hotchkiss, Unic, Berliet.

There is a tendency to use lower final gear ratios than was the case four years ago. Thus 4 or 4¼ to 1 is common where 3½ to 1 was formerly used. In some of the very small, light, speed engines, for which a big final gear ratio is necessary, worm drive has been adopted The small Peugeot is an example of this. Another firm which has a very small engine, turning at 3000 r.p.m., maximum, has also adopted worm because of the low reduction required. These seem to be the only cases in which worm is made use of in France.

Many Cantilever Springs

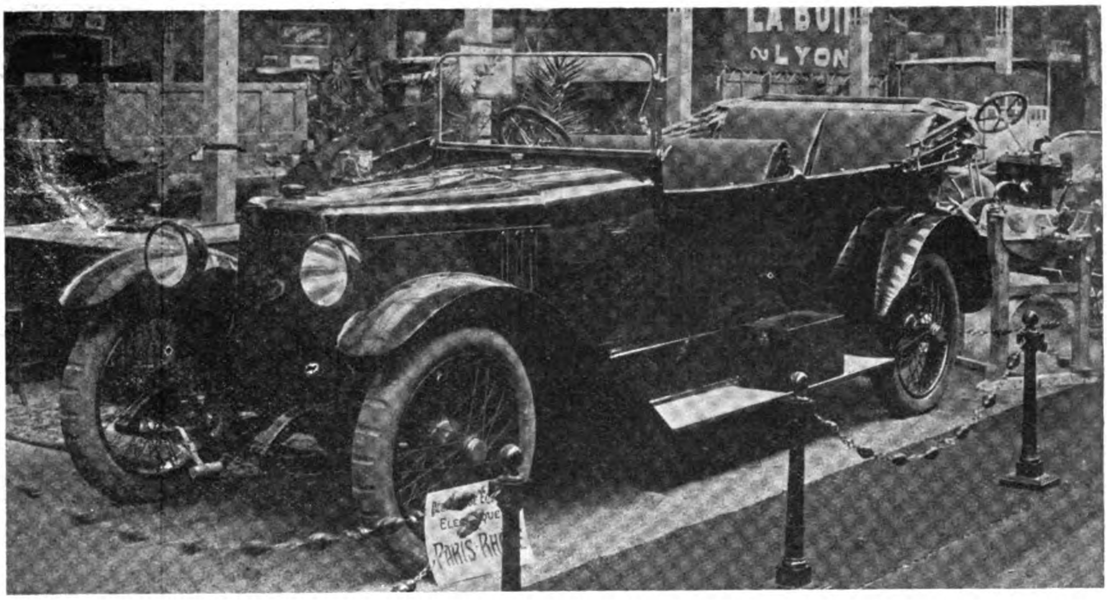
There is an equal unanimity in the use of cantilever rear springs, which have been adopted by Berliet, Rochet-Schneider, Renault, Unic, Peugeot, Zebre, to mention only a few.

More Rear Wheel Brakes

In more cases than ever brakes are all on the rear wheels. Experiments have been made with brakes on an extension of the propeller shaft, back of the differential, but these have not been followed up.

Peugeot adopted this type of brake on an intermediate type of car, but has dropped it on the latest model in favor of two pairs of shoes inside a single drum, each shoe covering practically a quarter of the circumference of the drum. This has been adopted in order to avoid the use of side-by-side brakes, and in working out the details the smallest amount of space has been lost by the brake pins and operating cams. With this Peugeot system practically the entire circumference of the drum is used as a braking surface.

The great majority of makers are satisfied to place



In the newest type of Rochet-Schneider the radiator is placed in front of the engine instead of behind it, and the body is fitted with upholstery which is completely detachable

the two brakes side by side. There are no external contracting brakes. Brakes on the front wheels promise to come along in increasing numbers for high-class cars only. Delage has set the fashion in this respect, and others who seemed inclined to follow are Hispano-Suiza and the Gnome Company with the Piccard-Pictet type car. Delage has exceptionally large braking surfaces, the size of his drums being 15.7 in. in diameter and 2.3 in. in width. In addition to the four brakes of this size on the wheels there is a hand brake on the transmission.

Sober Color Schemes

It is probably owing to the war that there is quite a sober tendency in color schemes. Dark blues, grays and blacks predominate; very few cars, indeed, are seen with gaudy color schemes.

The only novelty in bodies shown so far is the use of detachable upholstery. The back cushion, instead of being fixed in, is made detachable, just the same as the seat. This applies also to the side arm rests.

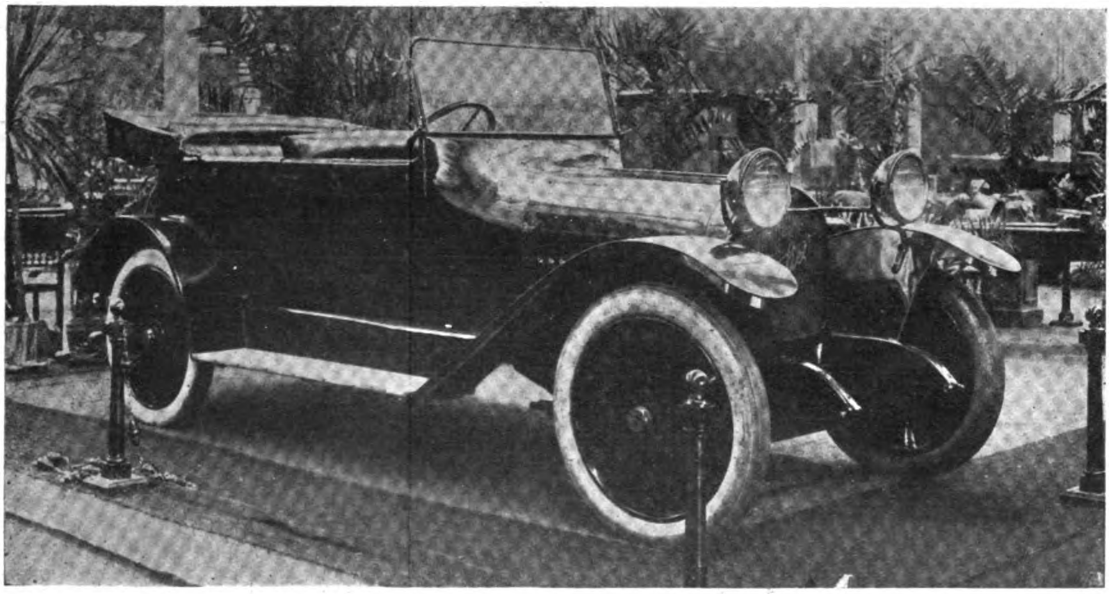
Where right-hand steering is retained the levers are always inside the body. It has not always been an easy matter to get them in, and on the new Brasier the brake lever is carried up much higher than the change-speed lever, and the handle placed at hight angles to the body of the lever.

Polished aluminum dashboards are being rather extensively used for high-class cars, with a polished-wood board for carrying the instruments only.

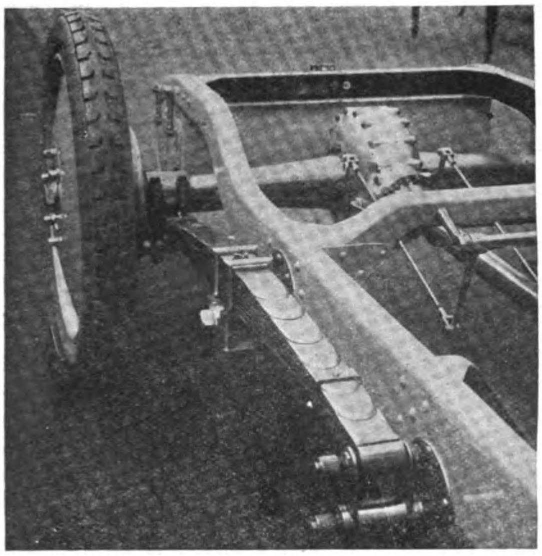
Two-Unit Electric Sets

Two-unit sets predominate for lighting and starting. So far as can be ascertained, the single unit is only employed by Berliet and Cotton-Desgouttes. There is no great amount of uniformity in the placing of the electric generator. Where the pump and magneto are driven from a cross shaft, the generator is generally put fore-and-aft on the valve side, as is the case with Delage and Fiat.

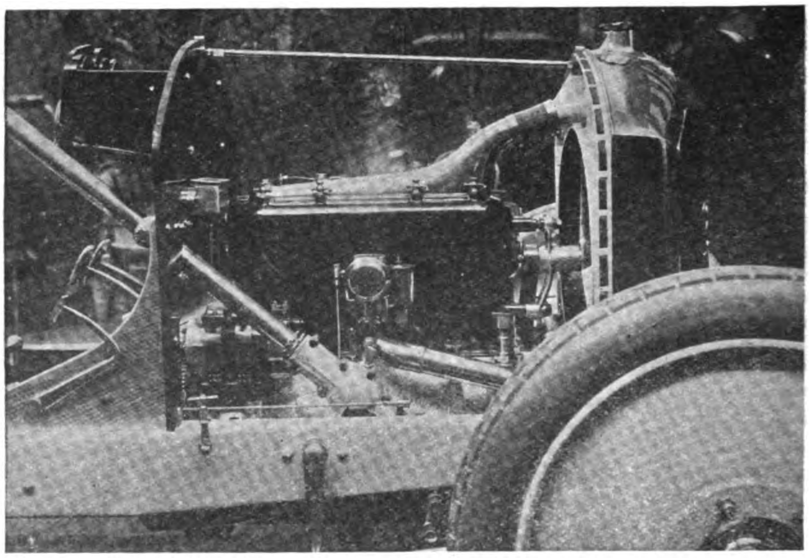
The only big firm building its own electric equipment appears to be Fiat. The others apply to specialists, of whom there are now a large number in France. One of the biggest companies is the S. E. V., of which Renault is a big stockholder. This company took over the small Bosch factory, abandoned in 1914, and in it built the Bosch-type magneto. The works have grown enormously since 1914, and now produce all kinds of electrical material for automobile use. Other big producers of elec-



The Berliet, which is produced by one of the most important manufacturers in the Lyons district, has been designed to approximate very closely the appearance of the average American car. It is equipped with a four-cylinder engine, North-East lighting-starting system and has disc wheels with detachable rims



Rear cantilever springs on the Rochet-Schneider



Carbureter side of the Rochet-Schneider four-cylinder engine

trical equipments are Bleriot, Grouvelle & Arquembourg, Nilmelior, and Lavalette.

Michelin is making a great effort to popularize steel disk wheels for use on passenger cars. It looks as if these will become popular, for they have the advantage of elegance, easy cleaning, and great strength. The only point that can be brought against them is that they are a little heavier than wood. The two biggest makers, Fiat and Renault, are not adopting Michelin wheels. The former will make use of Sankey type steel-spoke wheels, while the latter is using his own type of detachable wood wheel. There is no doubt, however, that wood is losing ground rapidly, even for touring cars.

Berliet Brings Out New Car

Berliet, who is the most important automobile manufacturer in the Lyons district, with a factory employing 10,000 workpeople, has come out with a new five-passenger car entirely on American lines. The engine is a four-cylinder, 3.5 x 5.5-in. bore and stroke, with detachable head, North-East electric generator and starter, a Berliet carbureter and a French magneto. It has cone clutch, three-speed gearset with center control, left-hand steering, spiral bevel gears with Timken bearings in the rear axle, and is sold complete with all accessories, including an American horn and speedometer.

Where it departs from American practice is in the use of cantilever springs at the rear and steel disk wheels with detachable clincher rims.

The finish is all black, and with the exception of the name on the radiator, the car looks like an American production. It is being sold complete at $2,350. According to a statement made at the Berliet factory, this will be the big production job of the works; in addition, a high-class car will be marketed.

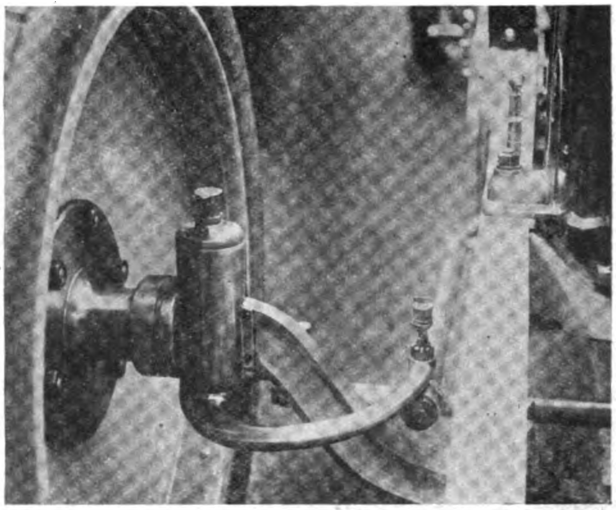
Centrally located gearset in the Rochet-Schneider



Application of dust covers to the steering pivots on the Rochet-Schneider

Berliet has capacity for production on a big scale. The original factory has been considerably enlarged during the war, but in addition to this an entirely new factory has been erected a few miles from Lyons, where the whole staff of 10,000 workpeople could be employed. The works are up to date and fitted with the most modern machinery. For the last 2 years Berliet has kept an engineer constantly in America for the purpose of buying machinery. In addition to this M. Berliet has himself made numerous visits to America so as to keep himself thoroughly acquainted with the latest production methods.

The factory is run entirely by electricity generated from water power in the French Alps and delivered at a very low price at Lyons. All iron, steel, aluminum and bronze are cast in the factory buildings, and the company makes its own forgings. During the war Berliet produced twenty-five trucks a day, in addition to 250 tanks of the Renault type every month, also shells and machine guns.

New Small-Size Peugeot

PEUGEOT has one of its new models ready, this being a light four-cylinder, four-passenger, evidently designed for cheap production. The selling price was not announced at the show. The engine has its cylinders, 66 by 105 mm., cast with the upper half of the crankchamber, and the crankshaft is carried in two ball bearings. Valves are on one side, with a single cap for each pair. The carbureter, a Zenith horizontal, is bolted up direct on the valve side, and exhaust manifold is cast with the cylinders. A single chain, placed at the rear, drives the camshaft and the magneto and electric generator shaft, and provision is provided for taking up slack by means of an idler pinion mounted eccentrically, with a lever on the outside of the casing for moving it and locking it in position. The electric generator is just ahead of the timing gear housing, and the magneto on the same shaft as the generator. The electric starting motor is placed down on the right-hand side of the engine.

This engine forms a unit construction with the clutch and gearset, the former being disk type and the latter giving four speeds and reverse, with center control. Steering is on the left side, and is of worm-and-nut type.

Engine cooling is by thermo-syphon, with the fan driven by belt off the crankshaft.

It is not known whether the French S.E.V. lighting set or the American Bijur will be used. Peugeot has adopted final drive by means of underneath worm, the final gear ratio being 4.6 to 1, with which the car has a speed of 36 m.p.h. Cantilever suspension is fitted at the rear with semi-elliptic in front.

Wheels are wood detachable with 710 by 90 mm. tires. Weight of this car, with four-passenger body, top, wind screen and all accessories, is 1670 lb. Gas consumption is stated to be 24 to 25 miles to the American gallon. Peugeot will market this car with six standard color schemes. Tread is 47 in., wheelbase 98 in. and body space 86 in. in length.

Peugeot Has Ten Factories

Peugeot will also get into big production at an early date. This company is now running ten distinct factories. At Beaulieu it has two factories for bicycles, motorcycles and light cars; at Mandeure it will build bodies only; passenger cars will be built at the Audincourt factory; at Sochaux two factories will be devoted to trucks, agricultural tractors, and steel, iron, bronze and aluminum castings; all the forges are at Montbeliard; at Lille there is a special factory equipped for bolts and nuts and general turning; at Issy-les-Moulineaux, near Paris, the company will produce aviation engines and spare parts; and at Levallois-Perret, near Paris, there will be the central repair establishment and storerooms for spare parts.

Peugeot has followed American construction methods very closely, and quite recently has commissioned Engineer Oliveau to remain permanently in America in order to keep the factory abreast of developments there. During the war Engineer Oliveau was chief technical instructor, detached from the French Army, at the American Motor Transport School No. 1, at Decizes. Previous to that he was engineer with Delahaye.

FIAT'S first post-war model to be offered to the public is a high-class, light car with four-cylinder engine, 65 by 110 mm., developing 23 hp. at its maximum speed of 2800 r.p .m. This is a type of car which it is believed will meet European conditions, where cost of maintenance has to be closely considered. So much more attention has been paid to workmanship and detail finish on the Fiat that it is interesting to know how it will compare in the matter of price with its French rivals. Up to the present Fiat has not made any announcement on price, stating that this cannot be settled until import duties are known.

Technically the Fiat engineers have made several changes.

The use of detachable cylinder heads is new.

Electric generator and starting motor are both cylindrical and carried in cylindrical extensions of the crankcase.

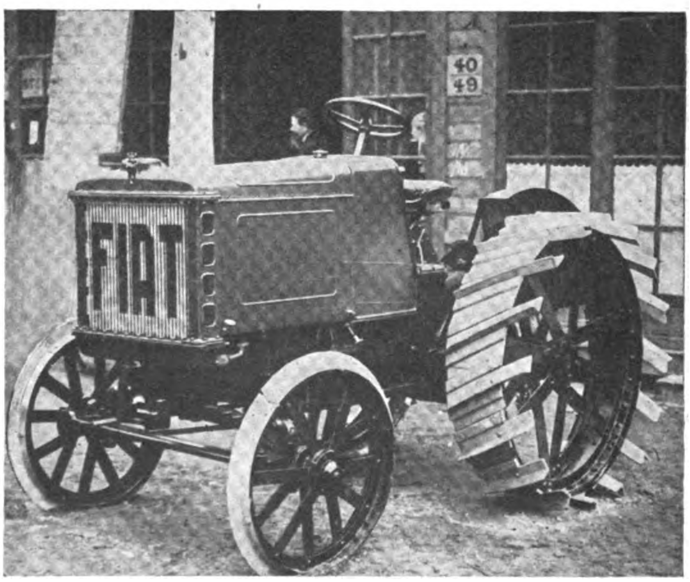
The engine and gearbox form a unit with three-point attachment to the frame, and the housing which carries the clutch and gears also acts as an oil reservoir for the universal.

The rear axle and propeller shaft housing is composed of two steel stampings welded together in a horizontal plane, with a cover plate on the rear of the differential housing, allowing the whole differential and propeller shaft to be withdrawn.

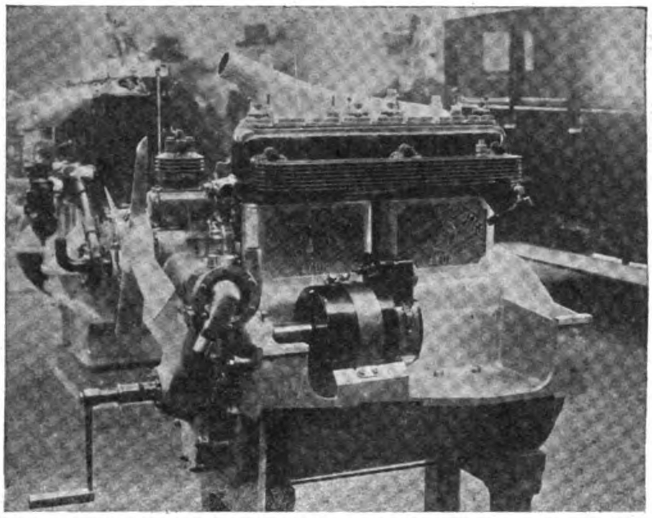
Spiral bevel gears are used.

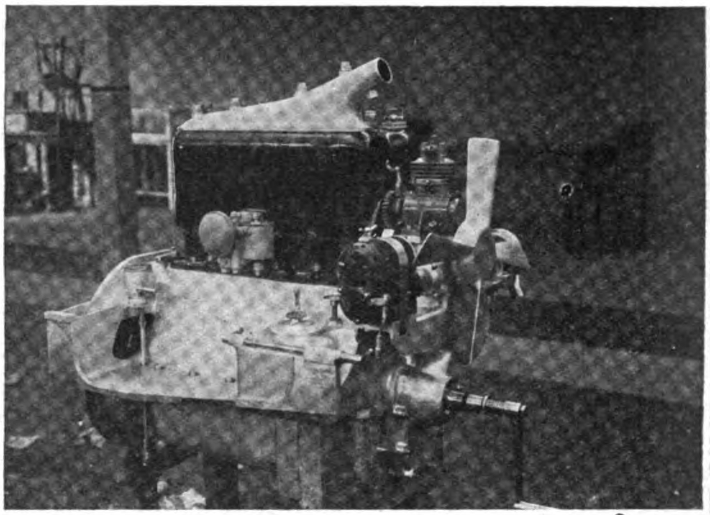
Two sets of brakes are side by side on the rear wheels, which are detachable steel spoke type.

Pressure fed gasoline has given way to a dashboard



The Fiat agricultural tractor appeared for the first time in France at the Lyons Fair





Both sides of the Cottin-Desgouttes four-cylinder engine. A characteristic is the use of a transverse shaft at the front to drive the water pump, magneto, fan and tire pump

tank. Right-hand steering is maintained, but the change speed and brake levers are inside the body.

Fiat has easily the biggest automobile factory in Europe, with a staff of 40,000 workpeople on the payroll, and a total of 70,000 people dependent on the factory. During the war the factory was producing 100 trucks and passenger cars a day, in addition to aviation motors, guns and special military material. Very close attention has been paid to export business, and production methods have been closely studied. At the present time Fiat has in America a commission composed of one of its chief engineers and five heads of departments. Fiat's program is two fours and two sixes, and although these are going to be high-class jobs, the factory is of such a size that it must produce on a big scale.

CITROEN, as reported in AUTOMOTIVE INDUSTRIES last week, who during the war was one of the biggest shell producers in France, is also putting on the market a light four-cylinder two or four-seater, with an engine of 65 by 110-mm. bore and stroke. The feature of this is the suspension, which consists of an inverted quarter elliptic spring above and one below the axle, these springs taking the drive and the torque. Other builders of light cars, these being two-seaters only, are Sigma and Philos.

France's Cheapest Car

THE cheapest car in the show, and in fact the lowest-priced car ever offered in France, is the A.S.S., offered complete for $950, with four-passenger body, electric lighting and starting, detachable steel disk wheels and all accessories. On this price it is declared that a reduction of $20 will be made if orders for 1000 cars are received before the end of March, and a further reduction if 10,000 are ordered before the end of the year.

The company responsible for this car constructed airplanes during the whole of the war, and is now transforming the airplane factory into an automobile establishment. Nothing more than a sheet metal body with four detachable seats was on view, it being declared that the complete chassis would be ready before the closing of the Fair. While there was a reluctance to give many technical details, it was learned that the engine will be a two-cylinder, two-cycle, of 75 by 120 mm. (2.9 by 4.7 in.).

A two-speed epicyclic gear is used and Ford-type steering. Springs are semi-elliptic in front and cantilever at the rear. A very extensive use is made of pressed steel, for not only the frame members but the two axles are of this construction. Interchangeable steel disk wheels are used with detachable clincher rims and tires of 765 by 105. Wheelbase is 112 in. and tread 56 in. Total weight is 1300 lb., and maximum speed 42 m.p.h., with a declared gasoline consumption of 25 miles to the American gallon. The lighting and starting systems are produced by the maker of the car; the lighting set comprises two headlights with dimmers.

The price of this car is attracting much attention. A two-cycle engine is not looked upon with a great amount of favor, and, as the firm has no past history of importance, it is difficult to judge whether the venture will be a success or not.

Delage has stepped right out of the small and medium-priced car into the exclusive type, with a six-cylinder, 3.1 by 5.9-in. bore and stroke, carrying all modern refinements and fitted with brakes on all four wheels. This is a high-class job and is listed at $5,700, chassis complete, with five wire wheels and tires, lighting and starting set.

Exhibition of Trucks

IN the truck section of the Lyons Fair not much new material was shown. Renault put on exhibition a 7-ton truck which had been produced to carry tanks. During the war it was desired to carry tanks up to the line aboard trucks, but as it is very rarely that a load of more than 5 tons is carried on one vehicle in France, the only means of moving the tanks was by means of heavy steamers. Renault therefore decided to build a special gasoline truck which would carry a tank, the total load of which is 6½ tons.

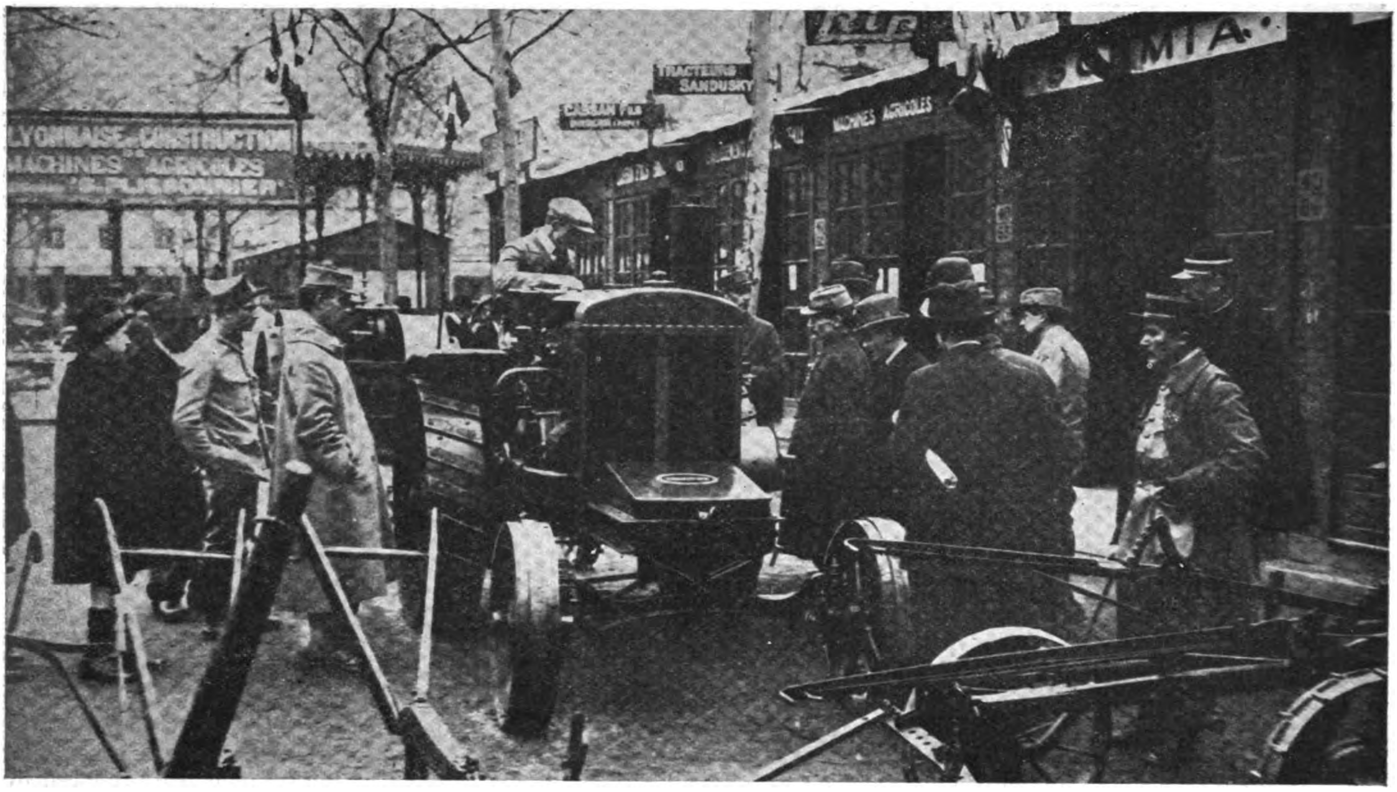
The engine is exactly the same design as that used on smaller trucks, but has a bore and stroke of 5 by 6.3 in. The radiator is back of the engine, inverted V type (the point of the V being toward the rear), and is composed of gilled instead of plain copper tubes. These changes had been made in order to give the bigger radiating surface necessary for an engine of this size.

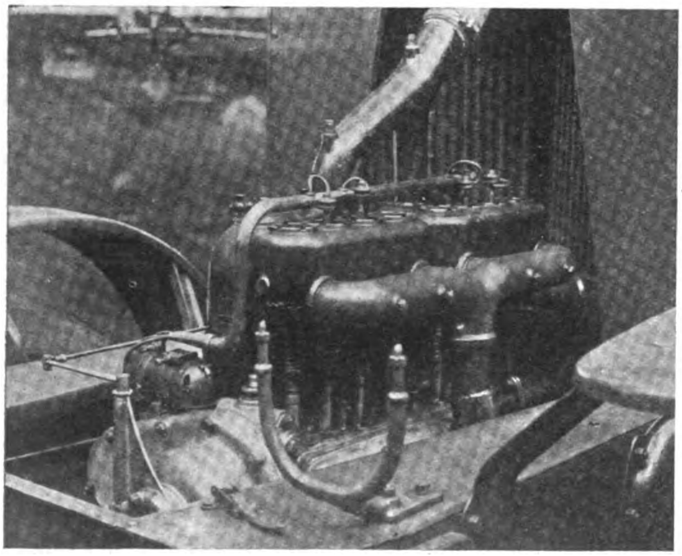
The only other feature of real interest was the final drive to the rear wheels, this being of the internal-gear type within cast-steel wheels, instead of a double reduction in the axle as on other Renault trucks.

Rear springs were underslung, and had a face width of 6 in.

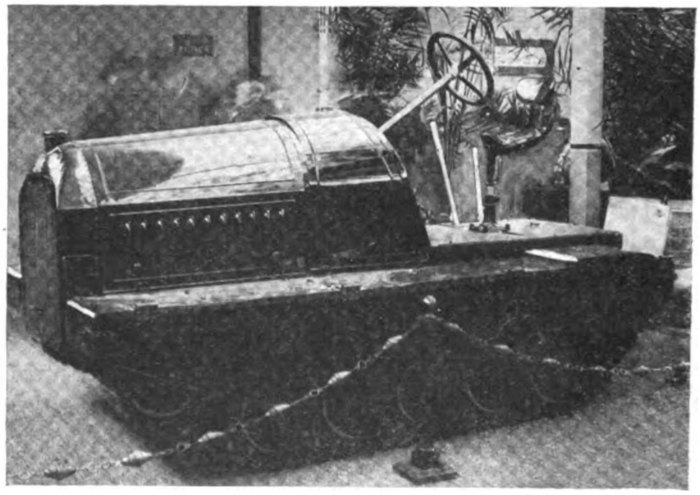
An extensive use was made of pressed steel for fender brackets, running-board brackets, etc.

Tires on this truck were 38 by 7, being singles in front

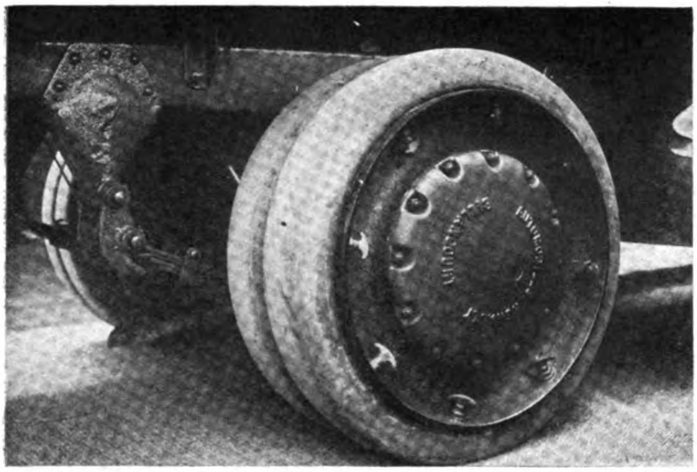


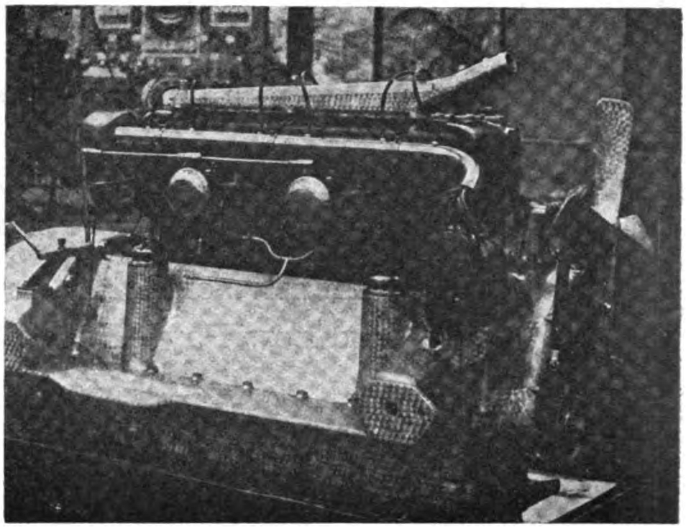


Top—General view of part of the Lyons Fair, with a tractor built by the Paris General Omnibus Co. in the foreground. Below—Peugeot tracklaying tractor



Above—Engine used in the Renault 7-ton truck. Right—Side view of the new Renault 7-ton truck, designed primarily to carry tanks





Above—Cast-steel wheel used on the internal-gear driven, 7-ton Renault truck. Right—Carbureter side of the Delage six-cylinder engine

and duals at the rear. These are the biggest solid tires seen on a French truck.

Agricultural tractors formed a separate branch of the Fair. The Fiat made its appearance for the first time in France. Other newcomers were the English Austin, which, like the Fiat, has a close resemblance to the Fordson, and the English Alldays & Onions all-purpose tractor.

The Paris General Omnibus Co. showed its own tractor, built under license from the Saunderson company of England. Peugeot put on view a self-track-laying tractor driven by means of a 35-hp. truck engine. This tractor has three speeds and reverse, main clutch control by means of pedal, and steering wheel which gives clutch control for the two tracks.

Renault also announced the production of a self-track-laying tractor, although the vehicle was not on exhibition. Having built tanks for about 2 years, Renault has had considerable experience in this class of construction. His tractor weighs 5900 lb., has a drawbar pull of 4400 lb., and exerts a pressure of 8 lb. per square centimeter. The tractor is listed at $5,600.

The claim is made by Michelin that the steel disk wheel allows tires to run cooler than the wood type. He states that there is a radiation of heat from the tire to the disk, this being quite noticeable after a long run, when it is found that the outer circumference of the wheel is hot, gradually decreasing in temperature as the center is reached. The Michelin wheel is carried by means of six studs, and is centered by the nuts on these studs. The six holes drilled in the wheel have beveled edges, and the base of the nut is also beveled, thus a wedging effect is obtained which assures a proper centering of the wheel and prevents the nuts working loose. Right-hand thread is used for the right-hand wheels and a left-hand thread for the opposite side. To facilitate fitting the wheels a tubular lever is supplied, this being passed through one of the holes in the wheel and placed on one of the studs, thus enabling the wheel to be levered up into position with a minimum of effort. The brace supplied for tightening the wheel nuts is also designed to fit the end of the jack handle, so as to enable the jack to be operated without bending. The jack is a new production Michelin is about to put on the market.

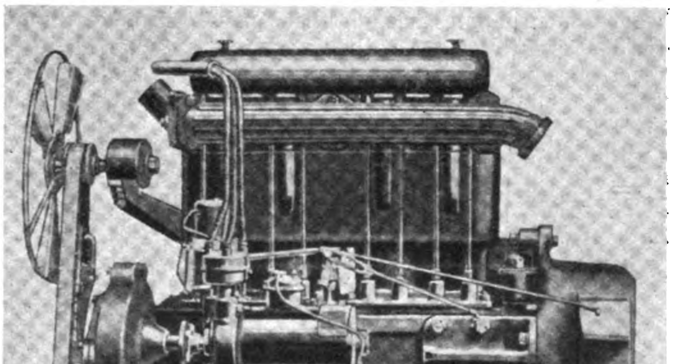
Mathews Four-Cylinder Power Plant

FOR 18 months the Mathews Engineering Co., Sandusky, Ohio, built for the U. S. Government equipment for war service in light houses, wireless stations, on docks, transports, etc. The requirements of the Government having ceased, the Mathews Co. now has placed on the market a four-cylinder engine known as Model F. This is recommended for use on passenger cars, trucks and tractors and for general power purposes in the machine shop, garage, etc. It is a four-cylinder, four-cycle engine of 3½ in. bore by 5 in. stroke, the total piston displacement being 192.4 cu. in. The S. A. E. rating of the engine is 19.6 hp. but the actual brake horsepower runs considerably above this.

The engine is made both in the open type and with a bell housing, the former weighing 400 lb. and the latter 440. It can be furnished with either three or four-point support. If the four-point support is desired, cast steel arms are used.

Lubrication is by the circulating splash system. The pump delivers oil to each of the splash troughs and also to the timing gears. The capacity of the system is 6 qts. All oil leads are external and a float indicator is provided.

While the engine is designed for thermo-syphon cooling and has large water connections, for some classes of work pump circulation may be desired, in which case a centrifugal pump is mounted on the left-side, and is driven from the accessory shaft. The magneto is then driven from the pump shaft.



Mathews engine built for U. S. Government for war service in lighthouses, wireless stations, docks, etc.

Foreign Competition Feared in England

Industry Apprehensive of Return to Old European System of Long Hours and Low Pay—U. S. Greatest Source of Worry

Special London Correspondence

ONE of the sources of fear for British trade on the part of some British motor firms has reference to the possibility of their European competitors returning to the low wages and long working hours which were common in Europe before the war. Belgium is the most cited instance, and certainly the labor conditions there before the war were the worst as compared with France, Germany and Italy, though the last named country was open to improvement on this score compared with France and Germany. The French motor works had a longer working week than the Germans and the rate of pay, though better than the Belgian, was lower than in Germany. The wage conditions in Germany now approximate more nearly to the British, but a longer week is normal, and if the movement toward the 44-hour week in England succeeds—and it is likely that such will be the case in the engineering trades—the discrepancy will be greater and more threatening to our competitive chances.

However, as regards Belgium, the following information may interest your readers, used to big earnings and a proportionately large output. I quote from a recent letter in the *London Times:*

"Previous to the war wages were always low in Belgium as compared with this country, and it was impossible for us to compete with many articles which were turned out in Belgium. The wages paid to skilled men in those times were from 65 to 70 centimes per hour for a good turner or tool maker, whereas a fitter would only get 50 centimes per hour. Girl labor was paid for at 30 centimes and extra efficient girl labor on heavy machines at 45 centimes. A special award of 75 per cent on all wages of mechanics has just been passed to meet the extra cost of living, so that the wages to-day for an ordinary mechanic are 1.25 franc per hour and for a skilled tool and gauge maker 1.50 franc per hour. The wages of the ordinary laborer have been increased to the round figure of 1.00 franc per hour, so that the laborer in a sense is not very far below a mechanic. Girl labor is now fixed at a minimum of 43 centimes per hour and a maximum of 55 centimes per hour."

Let us compare these figures with what we are at present paying in the engineering trades in England. Our very lowest price for skilled labor at present is 10d. (20 cents) per hour, plus 5½d. (11 cents), plus 12½ per cent., which is equal to 1.85 franc per hour.

Our highly skilled labor, *i.e., tool* and gauge makers, in many cases is paid as high as 1s. 6d. (30 cents) per hour, plus 5½d., plus 12½ per cent, or 2.75 franc per hour.

Ordinary laborers now get 7½d., plus 5½d (26 cents), plus 12½ per cent, or 1.55 franc per hour. Girls over eighteen get 5½d., plus 4d. (20 cents), equivalent to 1.00 franc per hour. If we compare these figures with those given above for labor in Belgium we shall see the difference in the cost of labor is from 50 per cent to 80 per cent more.

The British trade unions are well aware of these discrepancies on wage rates and their economical bearing on competition, but their officers point to the recent rapid development of industrial upheaval in these foreign countries as evidence of the trend toward a leveling up of conditions of pay and hours of labor and deduce from it the consolation that it is the knell of the unfair preferential conditions referred to. All of which deduction will be tested and the results demonstrated during the next two or three years. It is curious, however, that so far as concerns competition in the motor trade, there is far more anxiety as to American competition than regarding the combined total of European motor trade competition with British products, and this despite the fact that the rates of wage are much higher in the U. S.

General Instability Reflected in Car Market

The present instability of the motor manufacturing trade is shown by the fact that so many tenders for rough parts are subject to alteration and cancellation because of the further demands of labor for higher pay and the general state of industrial unrest, and it is felt that unless and until there is a substantial price drop in food and other necessaries, this instability will continue. Meanwhile precious time is being wasted in getting a start on normal products. Cars of good make are being listed privately at even $500 premium for early delivery, and in most cases these cars are merely pre-war models made up of materials already in stock when the war started. They are being modernized by being fitted with a dynamo and flywheel, electric starter and minor alterations in detail, but in few cases is there a genuinely new post-war model expected before July. The dealers, too, have to be considered, and as the manufacturers have told them what models they have in hand and the number for which material is available, so they have promised them not to list anything new, particularly appertaining to "popular" cars, until the pre-war stocks have been cleared.

It is reported that a group of French motor chassis makers have combined to pool, as it is called here, when purchasers of raw material. This is apparently the "comptoir" system extended to the motor industry, a system which flourishes over the Continent and in some places is identical with the German Kartel system. If British motor makers were less individualistic, or jealous of one another, as some would express it bluntly, they would pursue a similar policy having regard to the necessary limited scope of many of them.

Ministers continue to be questioned in Parliament as to their intentions in the matter of imports and the present embargo on certain articles, but eliciting statements

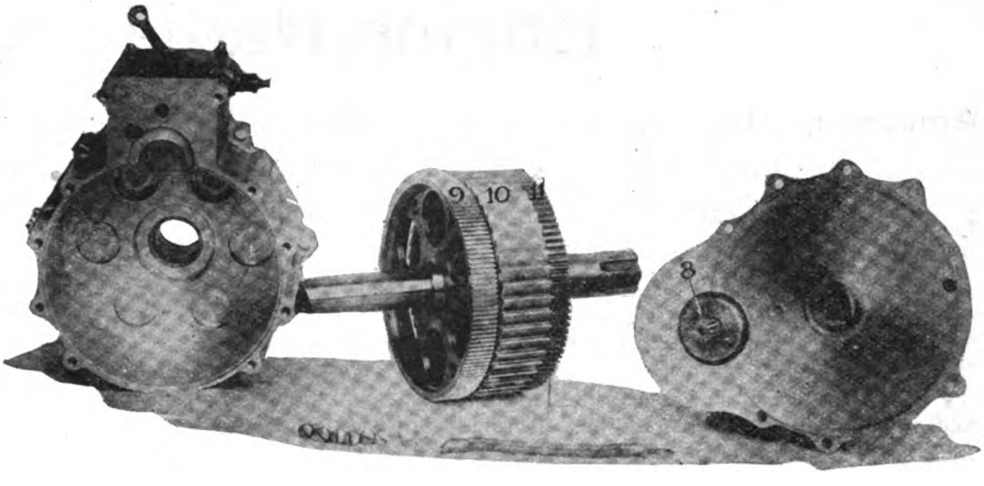
Liberty Starter for Aircraft Engines

Combines a Gear Reduction for Hand Cranking with an Electric Starter with High Reduction Ratio



Assembled reduction gear removed from housing

A NUMBER of features of interest are to be found in the new Liberty starter for aircraft engines, which is said to be also adapted to automobile engines. This starter was submitted to the Bureau of Steam Engineering of the Navy Department at Washington some months ago, and we understand that it passed all preliminary tests satisfactorily. As a result, the Navy placed an order for a number of starters which were delivered.

This starter forms a single compact unit, which combines both a hand starting gear reduction and the electric starter. The device aligns directly with the crankshaft on the engine, hence throws no extra strain upon the engine bearings, and the starting unit is practically a part of the crankcase. As it is mounted on the end of the crankshaft (opposite the propeller end), the head resistance is reduced, and the need for radiators of unusual shape is obviated. This starter with hand cranking attachment is said to weigh about one-third less than a separate hand and an electric starter together.

A factory is now building for the Liberty Starters Corp. in Poughkeepsie, N. Y., and when this is completed the manufacture of starters for the Navy and Army, as well as for export, will be continued. It is believed that as airplanes come into civilian use starters will be found just as necessary as on motor cars. Starting an airplane engine, however, has proven to be a much more difficult problem, because the latter has no flywheel, and the starter therefore must be attached directly to the crankshaft. In the Liberty starter, a double reduction gear is used, giving a reduction of 21:1 for hand starting and 240:1 for electric starting. An eccentric gear is used in order to obtain this high reduction ratio in a compact space. The Liberty starter weighs less than 29 lb. and is said to be capable of developing a starting torque of nearly 2000 lb.-ft. on the crankshaft.

The starter is entirely self-contained, and when it has performed its function as a starting device, it acts as a small flywheel, avoiding the necessity of meshing and unmeshing gears or engaging clutches. Provision is made on the starter case for the attachment of synchronizing gears, a generator or starting magneto (in case the engine is fitted only with magneto ignition). By the attachment of the generator, current can be supplied for recharging the starting battery as well as for lighting and wireless service.

The Principles of Cooling of Airplane Engine Radiators

Amount of Heat Which Radiator Must Dissipate—Law of Heat Transmission from a Surface to a Fluid Flowing Over the Surface—Horsepower Expended in Overcoming Head Resistance of Radiator

By H. B. Irving, B. Sc., A. F. Ae. S.

WITH the advent of the airship and airplane the problem of the cylinder cooling of light weight internal combustion engines has taken on a new and more complex aspect. In the case of the automobile the main consideration is simply to provide for the requisite amount of cooling of the cylinders; the questions of weight and head resistance do not, as they do in the case of the airplane, assume any very great importance. In the case of the automobile, too, the question as to the relative advantages or disadvantages of air cooling over water cooling is now scarcely ever considered, and water cooling is generally adopted as being the only practicable method. The relatively high speed at which an airplane moves, as compared with the speed of most automobiles, makes it necessary for the feasibility of air cooling, even in the case of the largest engines, to be reconsidered.

Cylinder Dimensions of Aero Engines Increasing

During the past few years the power and cylinder dimensions of air-cooled aero engines have been steadily increasing. With engines of moderate power there does not appear to be any very decided preference for either one or the other type. On the one hand, the air-cooled engine is generally lighter than the water-cooled engine. but, on the other hand, it usually is not so economical in running as to fuel and oil,* and, therefore, has to carry a greater weight of these for a given radius of action. In addition, the water-cooled engine probably scores on the whole on the point of reliability. When one comes to really large power units, however, there does not appear to be any doubt but that the water-cooled engine holds the field. The present article is chiefly concerned with the principles governing the design of radiators for water-cooled engines, but these principles apply to a certain extent also to air-cooled engines.

The question which arises at the outset is: How much cooling will the radiator have to perform? or at what rate will heat have to be dissipated for a given engine?

Now, all internal combustion engines as at present constituted, if they are to run satisfactorily and not give trouble due to overheating, must dissipate heat at a certain minimum rate. This rate of cooling is for water-cooled engines generally referred to as the "jacket loss," and does not include the heat lost in the exhaust gases. Many tests have been carried out in order to determine both its amount and its manner of dependence on the various factors involved, such as strength of explosive mixture, revolutions of engine, compression ratio, etc. In the case of most aero engines the following simple rule is probably quite sufficiently accurate for the purpose of radiator design:

The "jacket loss" is equal to the heat equivalent of the b.hp. developed by the engine.

If the engine is enclosed so that heat loss by convection and radiation from the various engine surfaces is small, then practically all the heat equivalent of the b.hp. of the engine is contained in the water leaving the cylinder jacket and has to be dissipated by the radiator. On the other hand, however, if, as is often the case in airplanes, the engine is exposed to more or less strong currents or eddies of air, a considerable proportion of the total amount of cooling required is done by the cylinder jacket and other surfaces of the engine, thus leaving much less cooling to be done by the radiator. The amount of this auxiliary cooling for a given engine will depend upon the disposition of the engine relative to the airplane, and upon the speed of the airplane. The data available at present are only sufficient to allow of a very rough estimate as to its magnitude, and further information on this point is much to be desired. Valuable data might be obtained from test flights at constant speed with engine at full power, observations being taken of the inlet and outlet water temperatures and engine revolutions. From block test results the jacket loss corresponding to the revolutions (at full power) could be obtained and compared with the amount of cooling done by the radiator. The difference would then give the auxiliary cooling of the engine parts at the air speed at which the test was carried out. This again might be compared with the auxiliary cooling obtained with the engine placed on a test stand in a current of air produced by a fan.

Laws of Heat Transmission

From the foregoing it would at first sight seem to be advantageous to leave the engine exposed to the wind as much as possible, so as to reduce the cooling required to be done by the radiator to as small an amount as possible and so to save weight by needing only a small radiator. But here the question of resistance comes in, and it has to be decided whether the extra resistance incurred by not enclosing or fairing off the engine does not counterbalance the saving in weight and resistance due to the smaller radiator.

Before going into the cooling of the radiator as a whole, it will be as well to consider the general laws of heat transmission, in so far as they enter into the problem of the cooling of the airplane engine or radiator.

Consider, then, a hot surface over which a gas is flowing with velocity v, and let the difference in temperature between the surface and the gas be θ. The law of heat transmission for such a case was first enunciated by Os-

*While this statement is absolutely correct, we believe that it is susceptible to the wrong interpretation that air cooling tends to decrease the fuel and oil economy. We believe it should be pointed out that the high fuel and oil consumption of most air-cooled aero engines is due to the fact that these engines are rotary engines.—Editor.

bourne Reynolds in 1874.* If h is the rate of heat transmission per unit area of surface the law states that

$$h = a\theta + b\rho v^{n-1}\theta$$

where a and b are constants, ρ is the density of the gas, and n is the index of v in the expression for the resistance of the surface. Usually $n = 2$, that is, the resistance varies as v squared, in which case

$$h = a\theta + b\rho v\theta$$

It will be seen that the term $a\theta$ represents the cooling which is obtained when the velocity v of the gas over the surface is zero; it may be called the "convection" term, in distinction from the velocity term $bv\theta$. For a given difference of temperature θ, the "convection" term remains constant with increasing velocity, while the velocity term increases in proportion to the velocity, and it may be assumed that, in the case of the airplane radiator, at air speeds above 20 miles per hour, the "convection" term becomes negligible in comparison with the "velocity" term. The law of heat transmission, as generally applicable to airplane radiators, then becomes

$$h = b\rho v\theta,$$

thus signifying that the rate of heat transmission is proportional to

(1) The density of the gas
(2) The velocity of the gas
(3) The temperature difference between gas and surface.

As a matter of interest, it may be noted in passing that, although to us at the present time it may seem perfectly natural, and, in fact, almost obvious, that the rate of cooling of a hot body should depend on the velocity of the wind blowing past it, only in recent years has the dependence of rate of heat transmission on velocity of gas become generally realized by engineers—if indeed it is generally realized even to-day. As before stated, the law of heat transmission was laid down as early as 1874. But until comparatively recently designers of boilers have used in their calculations empirical formulæ which did not contain any velocity term. It was only as late as 1909 that the late Professor Nicholson of Manchester, increasing the velocity of the flue gases in a Cornish boiler to 330 ft./sec., astonished engineers by obtaining from 8 to 10 times the usual rate of heat transmission.

Radiator Types

Modern airplane radiators are in most cases developments of certain types of motor car radiator. They may be broadly classified as

(a) Those in which water flows from top to bottom through tubes, the air flowing around or in between the tubes;

(b) Those in which the air flows through an assembly of horizontal tubes over and around which the circulating water passes. The tanks or containers at the top and bottom of the radiator are generally called the "header" and "well" respectively.

The second type, commonly known as the "honeycomb" type, has come into increasing use for airplane engines in recent years, as it lends itself to being made very light and able to withstand vibration. But in both types, and indeed in practically all modern radiators, the aim is to provide in as small a volume as possible and with the least weight the requisite amount of hot surface, *tangential to the direction of motion of the airplane*, over which the air can flow and carry away heat. The cross-section of the radiator, projected along the direction of motion, is made as small as possible, so as to reduce head resistance to a minimum, the resistance of the radiator then being mainly due to skin friction on the sides of the radiator tubes. Thus the type of radiator, often found on commercial automobiles, in which the upper and lower tanks are connected by a series of vertical circular tubes, has been modified for aero engine work, the tubes now being made either very thin and flat or of fine stream-line section.

*Proceedings of the Manchester Literary and Philosophical Society.

Returning now to the consideration of the law of cooling for a hot surface, the law

$$h = b\rho v\theta$$

will apply to each element of surface of the radiator, but it must be remembered that in an actual radiator the difference of temperature between surface and air will vary from top to bottom and from back to front of the radiator, since the temperature of the water falls as the water travels from top to bottom of the radiator, and since the temperature of the air rises slightly in passing through the radiator. If t is taken to be the difference between the mean of the water inlet and outlet temperatures and the temperature of the outside air, it will not be quite correct to say that the heat dissipated is proportional to t, but it will be very nearly correct. Also, the statement that the heat dissipated varies as ρ and as v (t constant) may be expected to apply to the whole radiator as well as to an elementary surface.

General Conclusions

Assuming that the resistance of a radiator varies as the square of the speed (an assumption which will in practically all cases be very near the truth), it is now possible to draw some very important general conclusions from the foregoing law of cooling. If S is the total cooling surface:

Rate of cooling of radiator varies as ρSVt
Resistance of radiator varies as ρSV^2
or varies as $(\rho SVt)V/t$
Horsepower expended in cooling varies as $(\rho SVt)V^2/t$

Now for a given motor at a given altitude—that is to say, at a given air density—the rate of cooling required for a given forward speed of the airplane with the engine all out is constant, and, therefore, ρSVt is constant. It follows, then, from the above, that the horsepower expended in cooling a given motor—

(a) Varies inversely as the temperature difference between radiator and air, and

(b) Varies directly as the square of the speed of the air passing through the radiator.

Conclusion (a) means simply that the higher the temperature difference between the radiator and the air, the less the horsepower expended in cooling. From the point of view of efficiency in water cooling, it is unfortunate that the boiling point of water is not higher than it actually is, or that no suitable liquid with a higher boiling point can be found to take the place of water in radiators. Another point in this connection is that in respect of temperature difference air-cooled engines are cooled more efficiently than water-cooled engines.

Conclusion (b) is of far-reaching importance. It places the designer on the horns of a dilemma; he has the choice between a small, light radiator of high resistance placed in free air, and a large, heavy radiator of low resistance, so placed or cowled that the speed of the air through it is low.

The advantages of the small radiator are fairly obvious. Its lightness is reflected in improved rate of climb, and it offers a small target for bullets. The latter of these is purely a war time advantage, and the former will probably be not so important in peace time as it was in war time, when a big rate of climb was of paramount importance. The disadvantage of the small free air radiator lies in its high resistance and consequent reduction of the speed of the airplane; the weight of the big

low resistance radiator, although reducing rate of climb, scarcely affects the speed of the airplane. If it were not for the entering in of considerations other than those which have just been mentioned, it would appear to be very doubtful whether the advantages of the small free air radiator will outweigh the advantages of the large radiator—especially in peace time, when the demand will probably be for efficiency, and when rate of climb will probably become relatively unimportant.

The adoption of the big low-speed radiator at once involves the problem as to how to obtain a low speed of air through it without the introduction of resistance other than that of the radiator itself. For instance, a common place for a radiator is in the nose of an airplane body, the air passing comparatively slowly through the radiator into the fuselage and out by vents in the side or bottom. Now, the additional resistance due to such a radiator cannot be considered to be only the resistance of the radiator proper, but it must be remembered that if the radiator were placed in the free air position, the nose of the body could be made streamline in shape and the resistance of the body reduced considerably; so that for the comparison of resistances to be just, it must be made between a streamline body with free air radiator and a more or less bluff body with nose radiator. Only experimental data could decide which is the better arrangement.

One method of reducing the speed of the air through a radiator suggests itself. The radiator could be placed in the free air and cowled, so that the areas of entrance or exit are less than the frontal area of the radiator. Here again it is uncertain whether or not the decreased resistance of the radiator due to the lower speed of air through it would be counterbalanced by the resistance which would certainly be added by the cowling itself, and the need for experimental data on this subject is emphasized.

The effect of altitude on the question of cooling is of interest. It is a well known fact that both the density and the temperature of the air decrease with increase in altitude. Also, the power of the engine usually decreases roughly as the density, but, by making special provision the power may be maintained constant up to considerable altitudes. Taking first the case in which the power is supposed to remain constant for all altitudes, suppose an airplane to set out on a climb at optimum climbing speed, the cooling being just adequate at ground level. At the same time as the rate of cooling is being reduced owing to reduction in density of the air, it is being increased owing to the increase in temperature difference between radiator and air. Generally these two effects are roughly equal, and the cooling remains the same. In practice the speed of optimum climb increases with altitude, and the cooling would increase in consequence. In this case, then, if the cooling is adequate at ground level, it is ample at altitudes, and, *à fortiori*, it would be ample if the power of the engine decreased with increase in altitude. In fact, the trouble usually experienced in practice is that there is too much cooling at altitudes, and the modern radiator is often provided with adjustable shutters for preventing—partially or almost completely—flow of air through the radiator. There is sometimes a danger—as for instance, in a prolonged glide at high altitude with engine shut off—that the water in the cooling system will freeze, or that the engine will become so cold that it will not "pick up" when the throttle is opened.

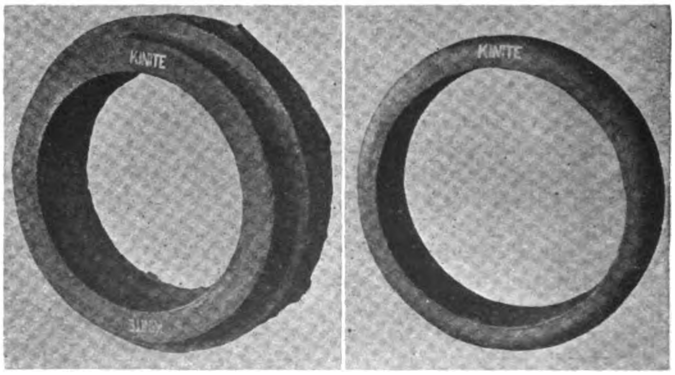
In conclusion, the present article has aimed only at presenting the general principles on which the design and location of radiators should be based. A large amount of experimental work on the subject has been carried out, but owing to the war the results are not yet available for publication. A grasp of the general principles, however, will lead to a ready understanding of the true significance of the data which will no doubt appear in due course.

Kinite—A Tungstenless High-Speed Tool Steel

A TOOL steel that is cast directly into the shape of the tool or die desired and which is claimed to possess the unusual quality of not changing shape or size during hardening, is one of the new developments in the steel industry. This new steel, known as Kinite, is made by the Kinite Co. of Milwaukee, and the following information regarding it is furnished us by the manufacturers:

Kinite is cast in specially prepared molds and has the appearance of a good smooth forging. A peculiar property is that it does not elongate under tensile strain nor decrease in cross-sectional area. It retains the shape and size that is desired until the breaking point is reached. Castings made from it are free from the defects and blow holes usually found in a casting. Unlike all other high speed steels it contains no tungsten. It will harden better than many forged products and when hard is very uniform and close grained, being one of the densest products of the steel family. It is high in heat resisting qualities and does not scale in the fire. These qualities make it an ideal material for making milling cutters, dies, taps and other tools having multiple cutting edges. As Kinite castings do not change their form during the hardening process, it is possible to make them so near the desired shape and size of the finished tool or die that very little machining or labor is necessary for completion. Dies requiring one hole or more are made with the holes cast in, thus saving the purchaser the cost of waste material and the labor of working the holes.

The unusual characteristic of not changing shape or size during hardening makes it possible to produce large dies in one single piece instead of many small pieces where ordinary die steels are used; and also saves from 20 to 70 per cent of the labor necessary to finish such dies after they are cast.



Rough Kinite castings just as they came from the fire

Some of the many kinds of tools that require hardening after finishing and which must retain their original shape and dimensions after hardening are: Blanking, stamping, forming, perforating, drawing and threading dies; plug, surface and snap gages. Kinite is also valuable for making machine parts that must resist heat and wear which are subject to great abrasive action while in service. It has been found that annealing boxes can have much thinner walls when made of this material and that they retain their shape and original weight through many more firings than when cast or malleable iron is used.

Castings made from Kinite can be annealed and rehardened many times without losing any of their properties.

The FORVM

Life of Fabric Disc Universal Joint

By F. R. Blair

IN view of the very general interest and curiosity among members of the engineering profession as to the performance of the so-called "fabric disc" type of universal joint, we believe the inclosed illustration will be of interest to your readers.

It is an un-retouched photograph of a Flexite Disc, one of two used in a coupling between the type B Quartermaster's truck motor and test dynamometer.

This particular disc had run a trifle over 3000 hours of actual service when it was photographed. It will be seen that the holes are round and true, that the fabric is nowhere cut but bears plainly the marks of the buckle plates and distance plates.

The depressions made by the radial teeth of the buckle plates (name given to the heavy plates opposite the spider arms) are approximately 1/32 in. deep, those made by the corrugated spacing plates being somewhat shallower, but in neither case is the surface of the disc in any degree broken.

Couplings of this construction in use on the rear propeller shaft of a 5-ton truck have been operated in excess of 20,000 miles in miscellanueous traffic with the discs showing similar condition at the end of that time.

Fuel Economy

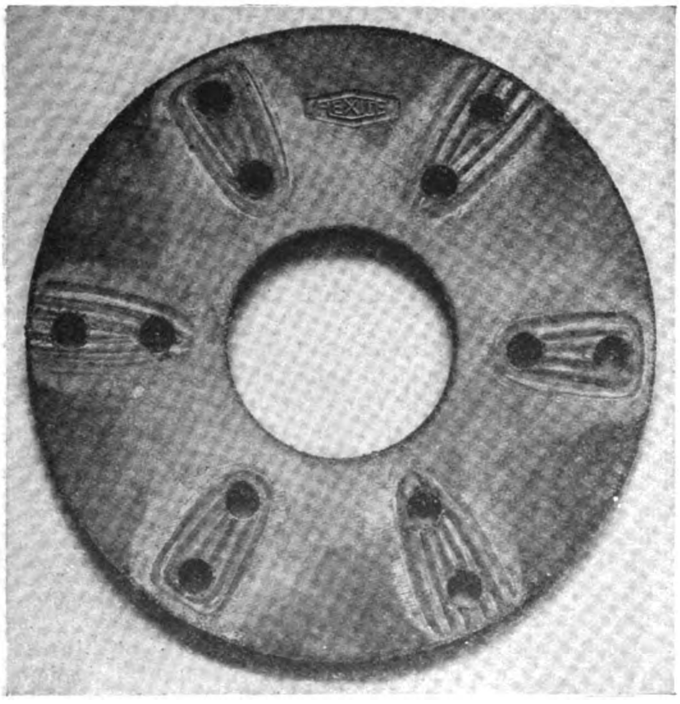
By R. M. Gaston

MR. POMEROY'S engine tests as given on page 432 in the issue of Feb. 20, 1919, permit comparison with American results. His tests are unusually complete in that they cover a wide range of loads at a speed range of 3 to 1. The accompanying curve shows the results of engine B with full size valves. The left-hand vertical scale shows the fuel consumption per brake horsepower hour, while the right-hand vertical scale shows the approximate thermal efficiency.

The curves illustrate clearly the falling off in efficiency at light loads regardless of the speed. In fact, it is somewhat surprising to find such small differences in efficiency at any particular horsepower output at the various speeds.

The Franklin car can easily cover 40 miles per gallon, and if the distance is covered in two hours, the consumption is only 4 pints per hour. Assuming the tractive effort to average 50 lb. and the mechanical efficiency between the engine and rear tires to be 50 per cent, the horsepower is only 5. The fuel consumption under these conditions is 0.8 pint per horsepower-hour, which corresponds to about 21 per cent thermal efficiency. Mr. Pomeroy's tests do not even approach this as the 5-horsepower efficiency at 800 r.p.m. would be about 1.2 pints per horsepower-hour. The output of the two engines is so similar it would be reasonable to install them on cars of the same size. The Franklin is apparently able to perform the same work on about two-thirds of the fuel.

The mechanical efficiency is taken considerably too low. In fact, tests made by the Franklin company itself have shown that the transmission efficiency on direct drive may be as high as 98 per cent and the rear axle efficiency 96.5 per cent, making the combined efficiency about 95 per cent. While this is the very limit, the transmission efficiency in a car in good condition can never drop to anything like 50 per cent.—Editor.



Universal joint disc dismounted after long use

Auxiliary Motor Trucks

THE Benzwerke Gaggenau supplied to the Spanish War Department at the beginning of the war a number of military trucks, which were designed to go with the mobile motor truck column. These auxiliary vehicles are used for various purposes such as carrying additional fuel for the trucks, portable workshops for field repairs, or the motor trucks themselves in case of a bad breakdown, to prevent them falling into the hands of the enemy. They are driven by four-cylinder gasoline motors, rated at 44-50 hp. The cooling arrangements are made so large that they will keep the engine cool even when running free with the truck standing for a considerable length of time.

The bodies are used for four main purposes. The first is a reservoir truck divided into several compartments, and is made up of riveted sheet-iron tanks. The front part is for oil, and the back part for water, the central part which is much the largest being for the gasoline supply. Suitable gages enable the driver to see the amount contained of each kind of fuel. Pumps are provided by means of which the fuel, water, or oil can be fed into the tanks through detachable flexible hose pipes.

The second type is fitted up as a store for spare parts which are contained in cupboards and drawers. All requisites even up to spare tires and complete axles are carried.

If the transport truck is so damaged that it is beyond the assistance of the spare-part store, the auxiliary salvage truck comes into service. On the chassis there is a bed with railings on each side which are so arranged that they can be converted into a ramp from the back of the vehicle to the ground, up which the damaged vehicle is hauled by means of a rope windlass provided on the front of the truck. When in position, the damaged truck is held by means of the closed-up railing. If the vehicle is so badly damaged that it cannot be hauled, a revolving crane is erected on bearings which are provided for that purpose, and the damaged wagon is lifted up bodily.

The fourth auxiliary truck is a complete portable workshop which is of the greatest use, not only to the transport service, but also to the air service and other corps. It contains a 6.6 kw. electric dynamo, lathe, drilling machine, milling machine, grinding machine, band saw, forge, anvil, and work benches. The lower parts of the side walls can be opened and fixed in a horizontal position to increase the working floor space, the corresponding upper halves of the walls being folded upwards to extend the roof.

Production Involves Intensive Study of Human Side

Volumes Printed on Industrial Management, but None on the Human Side of Business Affairs

By Harry Tipper

IT is significant as indicating the times in which we live that we should find in a page advertisement in the New York *Times* of March 24 the following paragraphs:

Quotation No. 1

Life was hopeless and miserable enough for most working people in Russia to make them easy victims of Bolshevism. But their revolt is not only against material conditions. It goes deeper than that—it is a great outbreaking of hatred and despair against the industrial system itself, and against all who have helped to make such a system possible.

Quotation No. 2

Rational hours, good wages, a comfortable material environment—these things are necessary, but these things alone will not do it. These are great masses of people whom these things alone will not satisfy today.

Quotation No. 3

The thing they are seeking is a new spirit in industry; a spirit that will recognize and respect the personality of each man, so that each man may have freedom of self-expression through his work.

ANY man who puts together the things which are exhibited in the newspapers and other periodicals, day by day, must be impressed not only with the importance of the labor problem and the necessity for its thorough examination, but also with its imminence and the necessity for action of the right kind; if we are to avoid either the turmoil which is enveloping Continental Europe or the defiance of government and the demand for nationalization which is occupying the attention of Great Britain.

It is significant that back of all the political turmoil about which we are reading and the effects of which we are noting, lies the industrial unrest, and the industrial unrest is the direct outcome of conditions which are humanly unsound and are bound to change.

The tendency of the times is unmistakable. The harbor strike is still going on in the Port of New York, called for the second time because the awards of the first strike were not agreeable to the workers, in spite of the fact that the Government was called in by the workers in the first strike and the decision of the war labor board was denounced by the owners as favoring the workers too much. It is to be noted in the demand which was made for a strike to begin July 1, on the slogan, "no beer no work." While this suggestion petered out, it was not squashed until some 500,000 workmen had voted for it.

It is not only that demand follows demand and that the employer is unable to approach his labor costs and his production problem from the labor standpoint with any certainty at all; it is not even that Government consideration demanded that capital and management accept decisions to which they did not agree, but it is the general tendency for labor to defy the Government unless the decisions of the Government are agreeable with their demands and with their estimated requirement.

It will be noted that in the last 4 months the great triple alliance of labor in Great Britain, involving the transportation workers and the coal miners, have threatened a strike of a general character through the whole of that country three times because of dissatisfaction with the Government position and with the length of time dur-

ing which the Government has been attempting to arrive at a settlement of the questions involveu. It should not pass without attention that the Sankey Report of the proposed settlement of the coal miners' dispute, which has not yet been accepted by the workers because it does not sufficiently establish them, definitely limits the profit per ton which capital can secure and also definitely provides for a combination in the management of the industry by representatives of the workers together with representatives of capital or the owners.

It is necessary to recognize the fact that we do not live in the same world from an organization standpoint that we did in 1914 *when the war broke out. It is necessary to emphasize the fact that this conflict has changed the outlook and the ideas of whole peoples to such an extent that it may result in a more severe period of political uncertainty and, perhaps, warfare, unless measures are taken which are founded upon the deep-seated necessities of the human being as an individual and as a part of an organization and not upon the temporary and supposed requirements of a production method.*

It has been the boast of this country that we have been able to throw away methods of operation at any time when new methods presented themselves before our industries. We shall be called upon to justify this boast in a larger measure and under more critical circumstances during the next few years than at any time in the history of our development.

No Discussion of Human Nature

ONE SEARCHES IN VAIN THROUGH THE BIBLIOGRAPHY OF INDUSTRIAL PRODUCTION, THROUGH THE BOOKS UPON EMPLOYMENT AND EMPLOYMENT MANAGEMENT, THROUGH THE WORKS UPON MOTION STUDY, EFFICIENCY AND INDUSTRIAL ENGINEERING, FOR ANY VOLUMES WHICH ARE DEVOTED TO A SERIOUS AND THOROUGH DISCUSSION OF THE HUMAN SIDE OF BUSINESS AFFAIRS.

The preacher, the socialist and the labor leader know a great deal more than the business man about the conditions among the workers, about their aspirations and about some of their necessities. It is true that their ideas as to the solution of the matter may be impractical and destructive, but that does not militate against the value of their discussions and their examination of the conditions, the aspiration and the tendency to be observed in this department of industrial affairs.

On account of this lack of study of the place of the individual in the industrial organization and the place of labor as a mass in its relation to management and capital in industrial work, the statements which have been made as to the increase of efficiency, the necessity for specialization, the value of standardization, the importance of this or that method of operation, cannot be regarded as accurate or scientific. If it is true that the whole production system depends for its value upon the action of the individual laborer and that all the mechanical processes are subsidiary to the human factor in the case, IT IS OBVIOUS THAT THE ALMOST TOTAL NEGLECT OF THE HUMAN FACTOR DESTROYS THE VALUE OF THE CONCLUSIONS WHICH HAVE BEEN REACHED AND MAKES IT NECESSARY TO DISREGARD THEM ALMOST ENTIRELY IN ANY PROPER EXAMINATION OF THE SUBJECT.

1—If this means anything, it means that the production manager, the engineer, the general executive, the capitalist must be prepared to throw away all preconceived notions and prejudices which have accumulated through the hundred years' operation of the factory system unless these can be justified by a more logical and more effective study than they have been given up to the present.

2—It means that they must be prepared to give far more attention to the Socialist, the labor leader, the preacher and the politician than they have been wont to do in the past, because these men have studied the human being more thoroughly and more carefully.

3—It means that the industrial executive and the capitalist must be prepared to examine afresh the real part which is played by capital, by management and by labor in the total necessities of production.

The statement that because the capital has been advanced the capitalist should control will not be permitted to pass unchallenged. In fact, it is being challenged with a greater voice every day, and the tones in which the challenge is spoken becomes less and less uncertain and more defiant. The statement that because management has been empowerd by capital to conduct the affairs of industry it must control altogether the conduct of that industry is being challenged in the same way, and the statement of labor, that it forms the bulk of the productive work and that it should control industry deserves to be challenged as it is being challenged by the management and the capitalist.

The New Objective

IF THIS INDUSTRIAL QUESTION IS TO BE SETTLED WITHOUT SUCH A PERIOD OF POLITICAL AND INDUSTRIAL UNCERTAINTY AND TURMOIL, AS WE WOULD HESITATE TO DISCUSS, IT WILL BE NECESSARY THAT CAPITAL SHOULD BE WILLING TO TAKE A SMALLER SHARE OF THE PROFIT OF INDUSTRY AND A VERY MUCH SMALLER SHARE IN THE CONDUCT OF INDUSTRY; THAT MANAGEMENT SHOULD EXTEND TO LABOR A SHARE IN THE RESPONSIBILITY FOR THE CONDUCT OF INDUSTRY AND PARTICULARLY A LARGE SHARE IN THE RESPONSIBILITY FOR THE CONDITIONS OF ITS OWN WORK, AND THAT CAPITAL, MANAGEMENT AND LABOR SHOULD ALL THREE SHARE IN THE PROFITS OF INDUSTRY AS WELL AS ITS RESPONSIBILITIES.

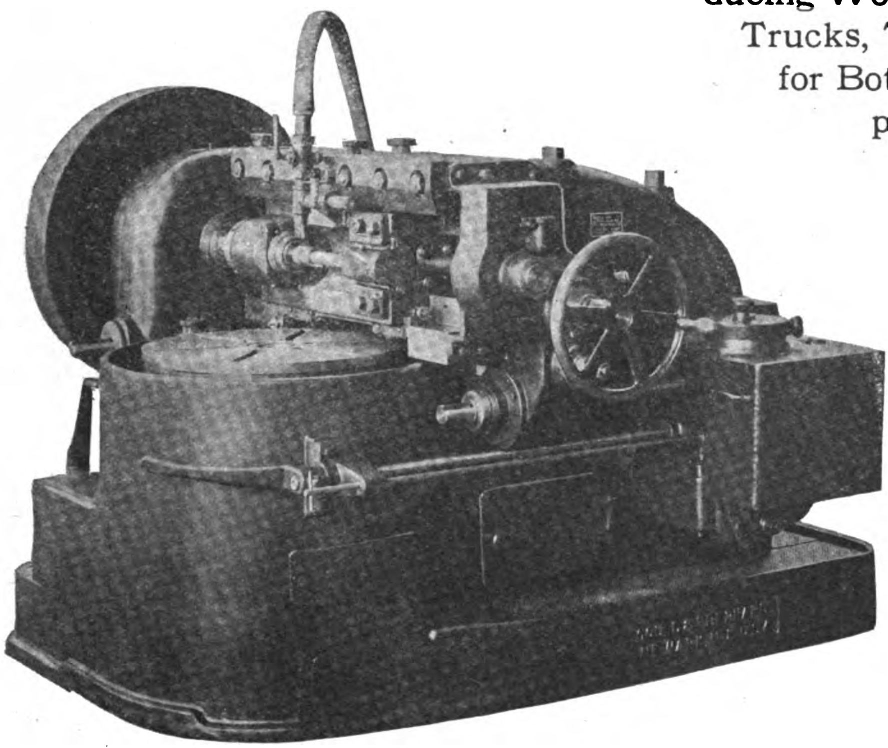
This can be done best by the individual organization arranging matters with its employees. The difficulty of accomplishing this in an orderly way through organized labor and organized groups of manufacturers is being illustrated in Great Britain to-day in the difficulties of arriving at agreement. The ease with which it can be done in the individual organization, provided that it is permeated by the spirit of square dealing, is indicated by the number of organizations of this kind which have been started in the last four years in this country without any turmoil and which are successfully handling the problems as they come up.

This is specifically an indication of the necessity for action, not for mere academic interest or so-called open-mindedness, but the necessity for serious examination and study of the problems and the decision along the best available lines. The final solution cannot be forthcoming at the present time, but the basis for an orderly solution has been provided in a sufficient number of individual cases to make it possible for any manufacturer to discover among these cases something which is applicable to his own plant. These cases should be studied, the fundamental reasons for their operations and the methods of their operation determined and action taken.

In this country we have the opportunity to settle this matter with less trouble on a better basis, with greater promise of progress than in any other country of an industrial character, but to do this it will be necessary for us to act, not merely to think about it.

G & E 18-In. Worm Wheel Generator

New Machine Specially Designed for Producing Worms and Worm Wheels for Trucks, Tractors, Etc—Adapted for Both Production and Experimental Work



G & E worm wheel generator. This illustration brings out strongly the robust construction of the machine

THE rapid increase in the manufacture of worms and worm wheels for use in motor trucks, tractors, elevators and worm gear reduction sets has created a demand for machines designed especially for this class of work. Such a machine is the automatic worm gear generator manufactured by Gould & Eberhard, Newark, N. J. It will automatically generate worm wheels with a tapered hob having a tangential feed or with a straight hob, which is fed into the worm wheel and not across it, and has means for cutting worm wheels with a fly tool. The latter method is particularly useful when carrying on a series of experiments, when it would be costly to make up special hobs for every wheel.

The success of worm and worm-wheel drives depends largely upon the accuracy and smoothness with which the worms and worm wheels are cut. The machine, to cut the worm wheels of the required quality must be unusually substantial; it must comprise the least number of parts, to eliminate torsional strains and to obtain the greatest amount of production from the hobs before grinding becomes necessary.

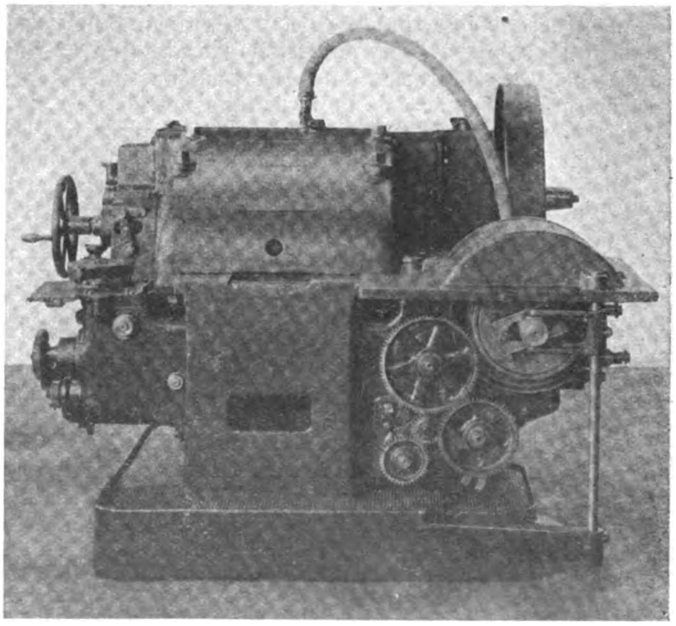
Worm-wheel hobs, by reason of their design, cannot be ground back as far as ordinary hobs, with the result that it is highly important that the machines in which hobs are used be of such substantial proportion that the hobs will cut the greatest number of worm wheels before getting dull.

The cutter spindle drive is through a powerful worm and worm wheel, with a large flywheel mounted directly on the end of the cutter spindle. It is also important that the work table be of substantial design and powerfully driven, so that it will be rigid under heavy strains. To insure this rigidity, the table is mounted in a permanent bearing in the base, while the cutter or hob carriage is mounted on a horizontal adjustable stanchion. This permits the work table to be arranged with a long cylindrical hub bearing, in addition to a conical and flat bearing and an indexing worm wheel of large diameter, which could not be incorporated if the work table was mounted in an adjustable carriage.

It is essential that the work table or face place be of convenient height for loading and unloading, and consideration has been given to this in the arrangement of the machine. All running parts are readily accessible and all necessary operating levers are conveniently located at the front of the machine, giving the operator full and instant control.

The machine is driven with a single pulley, and a high-speed clutch is incorporated so that it may be started or stopped instantly. This is operated by a lever at the front of the machine. There are six changes of cutter speeds, ranging from 58 to 183 r.p.m., making it possible to run various diameter hobs at the proper speed for the material being cut.

It is essential in a machine of this type to have a differential mechanism to enable the operator to take a second cut through a worm wheel, when using a tapered hob or fly tool, without losing the lead. The differential mechanism is also an advantage because it permits of changing the feed without changing the lead gears. When using a straight

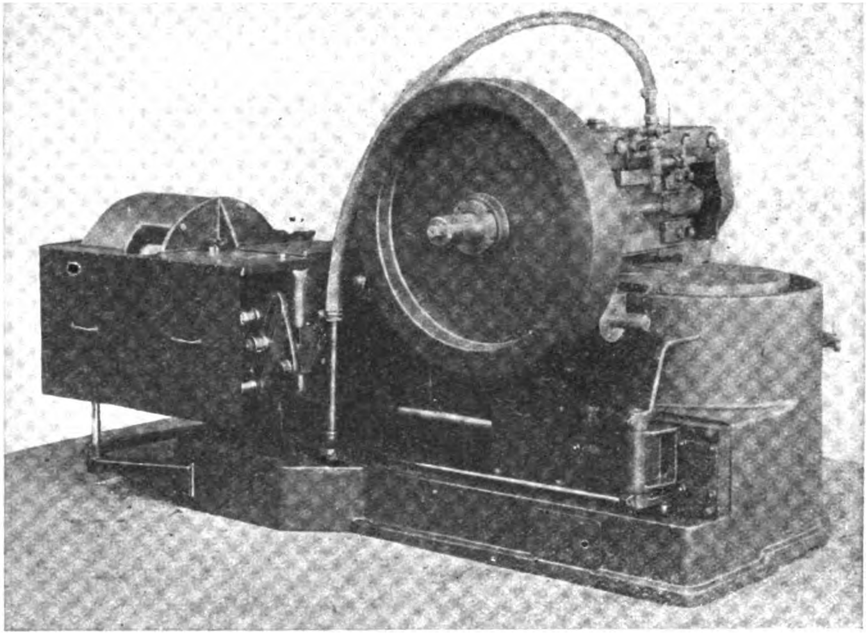


Rear view of the worm wheel generator showing belt pulley, clutch and gearing for changing cutter speeds

hob with automatic infeed, the differential is not required, and convenient means are provided for locking it.

A portable cutter arbor is furnished. The cutter carriage has an automatic tangential feed in one direction, and power return. An automatic stopping device is also provided, and may be set so as to stop the cutter carriage at any predetermined point. A graduated dial on the stopping device allows the operator to set the stopping mechanism to stop the cutter carriage at any predetermnied point.

The stanchion is provided with automatic infeed and power return. When feeding automatically into the revolving worm-wheel blank an automatic stop is provided, which is equipped with a graduated dial so that the operator can set the mechanism to stop at any predetermined point. When the tangential feed is being used, the stanchion is adjusted to the proper depth of tooth and then securely bolted to the base of the machine by four bolts. In adjusting the stanchion by hand, a dial graduated in thousandths of an inch is furnished, in addition to a scale and vernier, to set the hob and worm-wheel blank at the required center distance.



Side view of generator, showing flywheel on cutter arbor, hose connection for coolant, etc.

A centrifugal pump is regularly furnished with each machine to allow the use of a coolant, when cutting steel or bronze. It is attached to one side of the machine and is driven by gears. It may be conveniently disconnected by means of a clutch.

The machine will cut worm wheels up to 18 in. diameter; it will cut worm wheels with any number of teeth from 10 to 100 and with numbers of teeth from 102 to 120 except prime numbers. The cutting is done with hobs of one to five threads. A hob up to 5½ in. diameter can be swung and the length of hob may be anything up to 8 in. The cutter slide has a tangential travel of 10 in. The center distance from the cutter to the work spindle is limited to 3 in. minimum and 13¼ in. maximum. The center of the cutter arbor, which arbor is 1¼ in. in diameter, is located 7 in. above the top of the face plate. The net weight of the machine is 8600 lb.

Improving the Climbing Rate of Airplanes

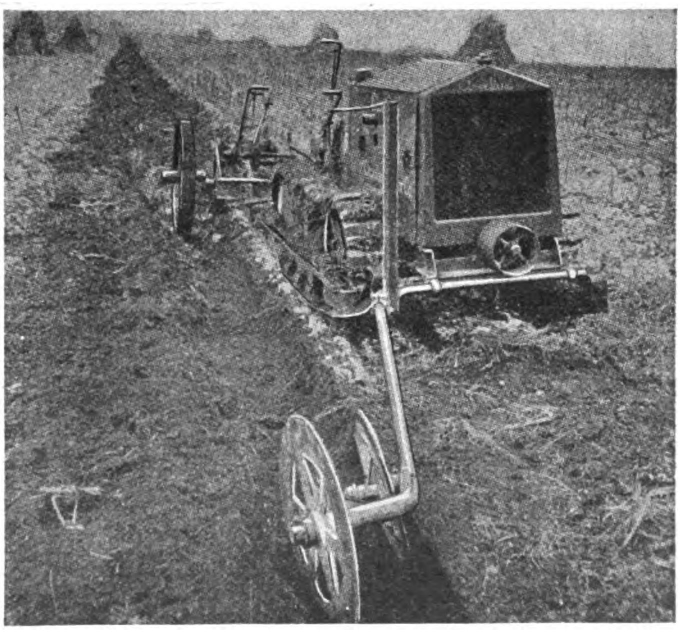
WRITING in the Zeitschrift für Flugtechnik und Motor-Luftschiffahrt, H. von Burberg states that when the wings of an aeroplane are being covered the fabric on the lower surface is sprinkled lightly with sand. Although the friction is thereby increased, the climbing power is considerably improved. This result is associated with the production of innumerable small eddies all in close proximity to each other on the undersurface of the wing, forming a species of air cushion. A fact closely associated with this is the phenomenon that when a machine flies direetly into a head wind it climbs better than when flying in still air with the same relative speed. The author considers that this effect is directly connected with the eddying air encountered by the machine.

Experiments are being conducted to test the effects of roughening different parts of the surface of propellers and streamline bodies, and these have so far given satisfactory results. They have shown that roughening the under-surface of the wing is favorable to the production of a cushion of supporting eddies.

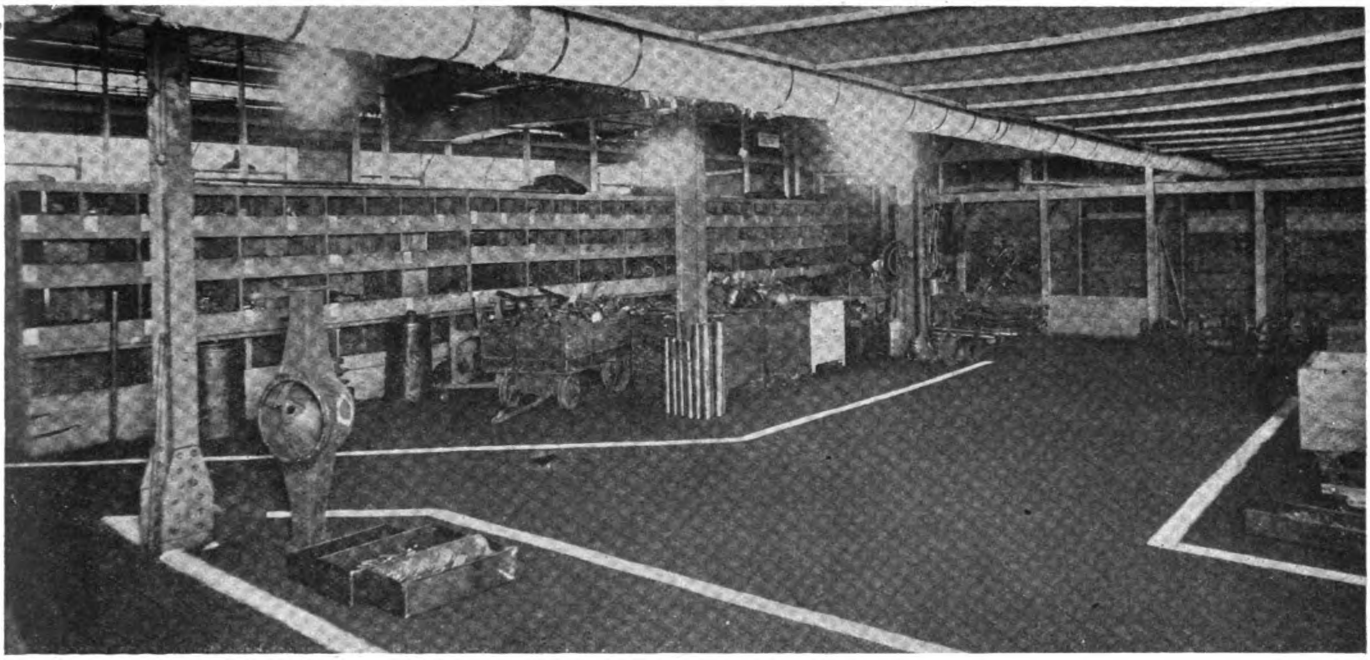
Willis Tractor Guide

A SELF-STEERING attachment for creeper type tractors is being marketed by the Willis-Flack Mfg. Co., Kansas City, Mo. It consists essentially of a forwardly extending tubular arm. The rear end of this arm is bent at right angles and is supported in bearings bolted to the front cross member of the tractor frame. At the forward end the tubular arm carries a pair of disk wheels running in the furrow. An upright of angle iron is secured to the arm at its bend and connects to a lever in front of the operator's seat, thus furnishing a means of lifting the guide when the tractor is to be turned at the end of the field.

The obvious advantage of a device of this kind is, of course, that the driver does not need to pay any attention to the steering, except in turning at the ends of the field, and is free to watch his plows. An indirect advantage is also claimed, namely, that with the guide the tractor can be run closer to the furrow than would be possible with hand-steering, and as a result the side draft can be reduced. While the guide is applicable to creeper type tractors generally, it seems to have been designed specially for the Cleveland, to which it can be fitted without drilling any holes. The runners are adjustable for 12 and 14 in. furrows. When not required the guide can be taken off in 10 min., it is claimed.



Application of the Willis Tractor Guide



Incoming parts and material are delivered either by train, motor truck, or trailer. The trailer comes from the Timken forging shop and is pulled by a gasoline tractor designed for this heavy haul work

Timken Solving Production Problem

Efficiently Operated Electric Trucks for Interdepartmental Transportation Reduced Truckers by 50 Per Cent—Use Elevated Containers

By J. Edward Schipper

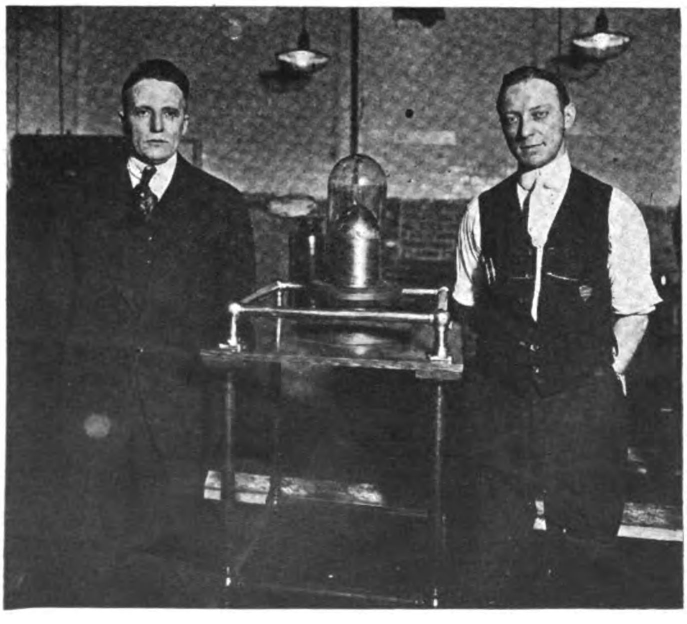
Part II

OWING to the necessity for scattering the departments throughout the gradually erected buildings of the Timken-Detroit Axle Co., it is of great importance that interdepartmental communication be maintained at high efficiency wherever it is necessary that such communication exist.

For example, between the material and the manufacturing departments there must be quick and good transportation of materials to the manufacturing department.

There must be rapid and good transportation of the incoming raw stock to the material stockroom.

The Timken factory has grown gradually, and it has been necessary to add buildings after buildings, until now there are approximately ninety buildings devoted to the business. In the particular series of fifty-seven buildings we are discussing, only motor truck axles are manufactured, with the exception of the Cadillac passenger car axles. Another group of buildings handles the passenger car production; another section produces the forgings. A certain amount of special work is purchased outside, although this is confined to very few products.



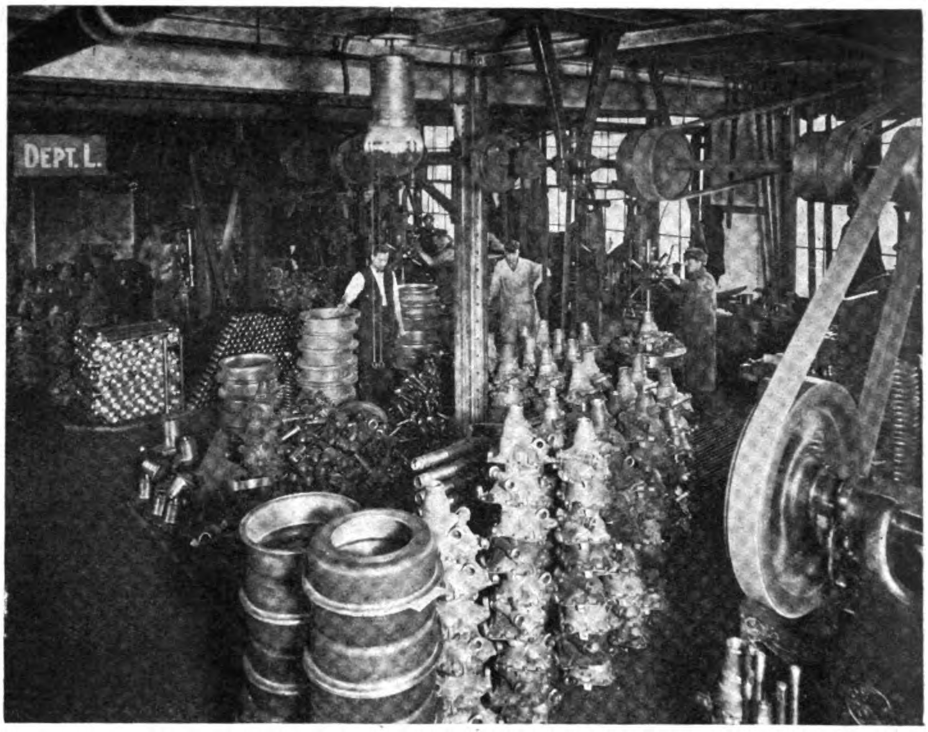
At the end of each month the night and day foremen of the cleanest department have their names inscribed on the shell, and this is kept in that department for a month

Visualizing these conditions, it is easy to see, in manufacturing the Cadillac-Timken axle, which perhaps is made in fifteen buildings, how vital it is that the movement of these parts—from raw stock to manufacture, from manufacture to heat-treatment, from heat-treatment to finishing operations, and from finishing operations to finished stock, and thence to assembly and shipping — be judiciously handled if the work is to go through smoothly. Consequently, interdepartment transportation has been given a great amount of attention. Recently a new system has been introduced which has reduced the number of men han-

dling the work from ninety-eight to fifty-four. This will be cut still further by completing the electric truck equipment now in use.

To accomplish this, standard boxes and racks, mounted on castors, are used. When one of these boxes is filled it can be pushed aside and an empty one introduced. The electric trucks are continuously on the move, picking up the filled boxes and carrying them to points where needed. This may be from the manufacturing department to the heat-treating room, or it may be to convey a load of forgings from the receiving room to the knuckle department. The boxes are quickly picked up by the electric truck, which has a platform lower than the space beneath the box.

The driver soon becomes expert in running the truck beneath the box, turning on the elevating electric motor, which raises the platform and lifts the box off the floor. The trucks are capable of traveling 7 to 14 m.p.h. They are equipped with electric horns, which allow them to proceed with high speed and safety down the aisles.

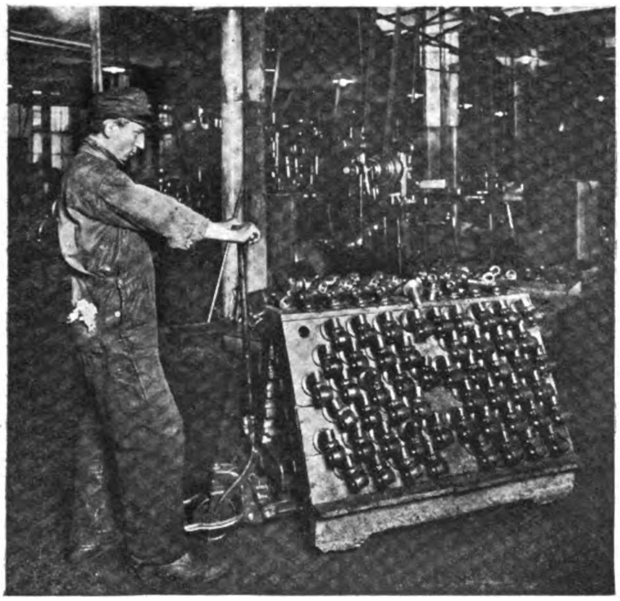


Carrier department, showing carriers for various types of axles all going through the same department

Naturally, with high-speed transportation between the departments it is necessary to keep the aisle space clear, which is done by vividly outlining them with white lines. It is made a special matter of duty to keep the aisle spaces clear, because obstructions in them would mean delay in transportation. It is estimated that since the introduction of the electric industrial truck, with the standard boxes and containers, and the clearing of the aisle spaces, transportation efficiency has gone up 400 per cent. Working on the regular schedule, the electric trucks travel over their routes.

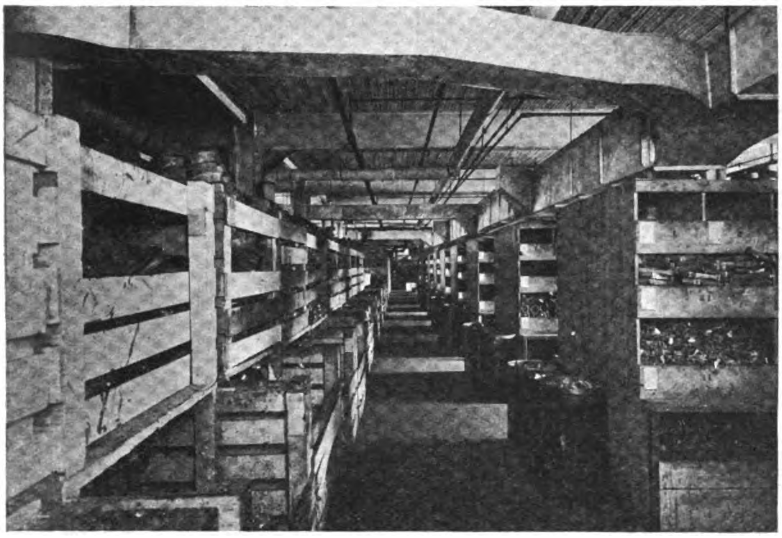
An observation in the raw material department indicated that an electric truck left every 10 min. loaded with a box of materials. Only 25 sec. elapsed from the time the electric truck arrived in the department until it had slipped its platform under the box, raised the box off the floor and started on its trip. Boxes of all the required materials are always waiting in the raw materials department, so that no delay exists at this point. An electric truck never has to stand and wait while a box is being filled. When it arrives in the department it travels up the aisle to the box it wants, slips its platform under it, the elevating motor is turned on, and in a few seconds it is off with its load to the department requiring that material.

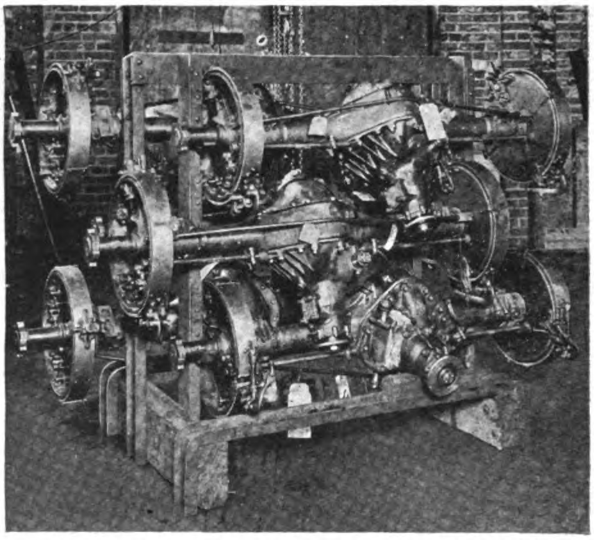
Realizing the importance of a clear aisle space, it has been made a matter of pride with the different departments to present the cleanest possible aspect, with ma-



Electric truck slipping its platform beneath a loaded box of parts

Racks of parts can be moved around the department by means of hand trucks which elevate the racks





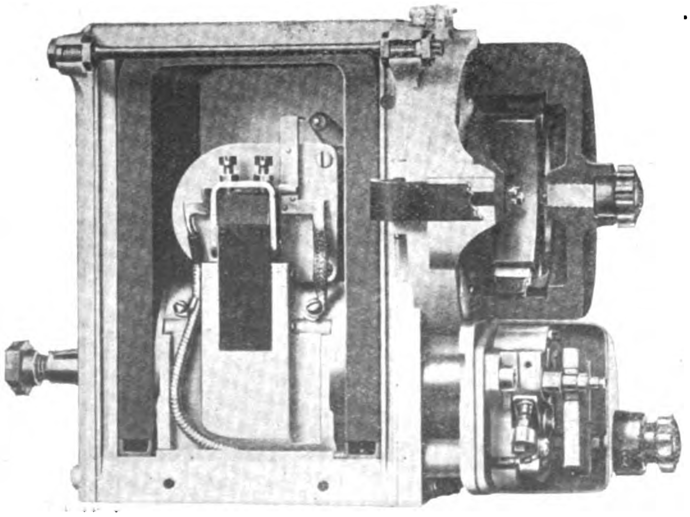
Left—Type of bins which clear aisle spaces for finished stock. Right—Back of finished axles. Note how rack is constructed so that electric truck platform will fit underneath, allowing for quick transportation

terials neatly arranged in racks or in some instances in piles, with nothing protruding into the aisle spaces. During the month an inspection record of departments is kept, and the one which has been cleanest is given a mark of recognition in the form of a shell, with the names of the night and day foremen engraved upon it. This shell is kept in a glass case mounted on a stand, and remains in the department for the month following that in which it was won.

New Dixie Automobile Magneto

A NEW series of magnetos for passenger cars and motor trucks, referred to as aero magnetos, has been placed on the market by the Splitdorf Electrical Co., Newark, N. J. The most apparent change from the former series is that the finish, instead of being black, is khaki. A single square carbon brush is used, heavier interrupter points, and more rugged construction throughout. The magneto is unidirectional. Micarta gears are employed, and the distributer block is made of Americanite. The Mason inductor principle, embodying the use of stationary windings and revolving fields, is adhered to.

The unidirectional principle may be explained as follows: Like practically all other ignition magnetos, the Dixie magneto generates an alternating current, comprising both a positive and a negative wave. It has been found in experiments with such magnetos that one of the waves is always stronger than the other, and in the aero-type magneto the negative wave is the stronger. The aero magneto is so designed that only negative waves are used for producing the sparks. The cam of the interrupter has two lobes, and the revolving field, or rotor, has four wings. When the rotor wings on the distributer end of the magneto leave the poles, the cam separates the platinum points. At this moment a spark is produced. When the rotor wings on the drive end of the magneto leave the poles, the cam holds the platinum points apart, with the result that no spark is produced. This explanation applies directly to a magneto designed for right-hand operation. In a left-hand type magneto the cam opens the platinum point when the rotor wings on the drive end leave the poles. In this case the position of the magneto is reversed, and the spark therefore is of the same polarity as with a right-hand driven type.



Part-sectional view of Dixie aero-type automobile magneto

Substitutes for Platinum

THE chief source of platinum is Russia, and since the revolution in that country the stocks of platinum in allied countries have been much depleted. Platinum owes its uses largely to its high melting temperature and to its resistance to attack by acids. It is extensively used for crucibles and for electric spark terminals. Extensive experiments have been carried on with the object of finding a suitable substitute, and some of the work done in France is covered in a recent article in *La Nature*.

Gold-platinum alloys, which have been available commercially for some years, contain about 12.5 per cent platinum. These alloys have the disadvantage of melting at 1200 deg. C., and softening at about 1500 deg. C., so that they cannot be subjected to great heat from the blowpipe without deforming. They resist acids very well and do not decrease appreciably in weight from one operation to another. They are generally used for work where a temperature of 1000 deg. C. is sufficient.

Gold-palladium alloys are capable of wider application and require less careful handling. They are widely employed in the U. S. A. by the names of "palan" and "rhotanium," usually in the form of crucibles, bowls, electrodes, etc. Their manufacture has now commenced in France. They can be heated without special precautions and resist the action of reagents better than platinum does. They contain at least 20 per cent of palladium and have the same color and appearance as platinum.

IN the article on the Campbell Transmission in our issue of March 13, the name of the manufacturer was inadvertently omitted. This transmission is the product of the Campbell Transmission Co., Buchanan, Mich.

The Lubrication of Motor Cars*

A Discussion of Methods Employed in the Lubrication of Steering Gears, Drag Links, Rear Axles, Springs, Spring Eyes and Road Wheels —Oil and Grease Retaining Devices

By Capt. G. W. A. Brown

PART II

FIG. 21 illustrates the method of oiling the universal joints of a well-known car. To the author's mind, this seems more a method of disposing of the surplus oil from a badly packed gear-box shaft than a serious attempt to lubricate the joint pin. In any case, additional measures for lubricating the universal joint would appear to be necessary.

Live Axle—The strictures which have been made on the antiquated methods at present in use for lubricating gear-boxes apply equally, in the author's opinion, to back axles, and, in the same way, the author is of the opinion that the ideal way of lubricating this important part of a car is that illustrated in Fig. 22. In this system a plunger pump, driven by a cam on the differential casing, supplies oil, as can be seen, to all the revolving surfaces, including the bevel wheels at their point of meshing. It will be noticed that the driving shafts are tapered; this of course is essential from a stress point of view, but use is made of this taper to wind oil along it to the wheel bearings, whence it drips off and returns to the sump at the bottom of the axle casing.

In the "Fergus" car, the back axle (Fig. 23) is lubricated on the splash principle, i.e., the bevel wheel dips in oil contained in the casing, but there is no special provision for oiling the road wheel bearings, nor is there any method of maintaining the level of the oil with certainty, although a certain quantity of oil is constantly draining into the case via the spring housings and the torque tube.

Fig. 24 illustrates a trough system of lubrication similar to that already referred to for the gear-box.

III. Steering Gear: Drag Link Connections

As usually arranged, these connections are the most inadequately lubricated parts of the car. Whether knuckle joints or pin and fork joints are employed, the method of treatment is the same, namely, to fit a grease cup on the joint and to surround the whole thing with a leather cover. The net result is that, after one drive on a wet day, if the trouble is taken to remove this leather covering, it will be found to be filled with water and mud. In any case, the author has noticed that there is a marked disinclination on the part of drivers of cars to fill grease cups, or even to turn them, the consequence of which is that rust soon sets in, accompanied by wear, and a serious accident may possibly occur.

In the "Fergus" car (Fig. 25), the lubrication of the steering gear has been carried out with the most commendable thoroughness. Here, it will be seen, provision is made for entirely filling the tubes with the lubricant, which finds its way into the ball and socket joints through suitable oil-ways, while the joint itself is rendered oil-tight by a metal cap held in contact by a spring.

A design of the author's, which also obviates the difficulties

*Paper presented to the Institution of Automobile Engineers, London.

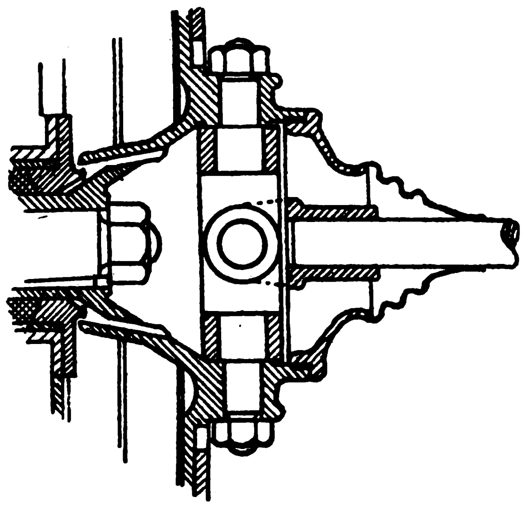


Fig. 21—Haphazard method of lubricating universal joint

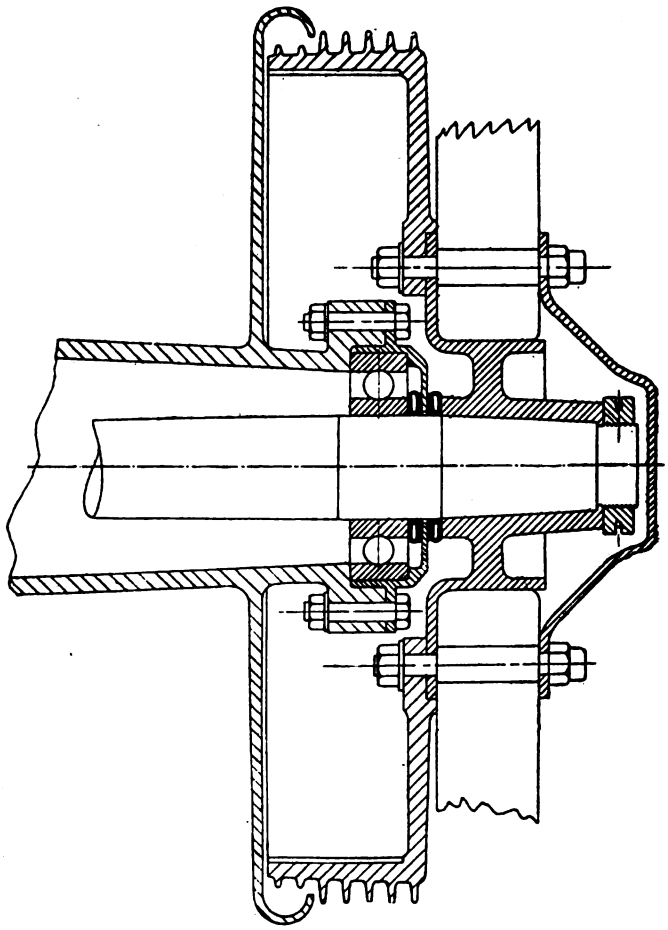

Fig. 22a—Outer end of oil-lubricated axle

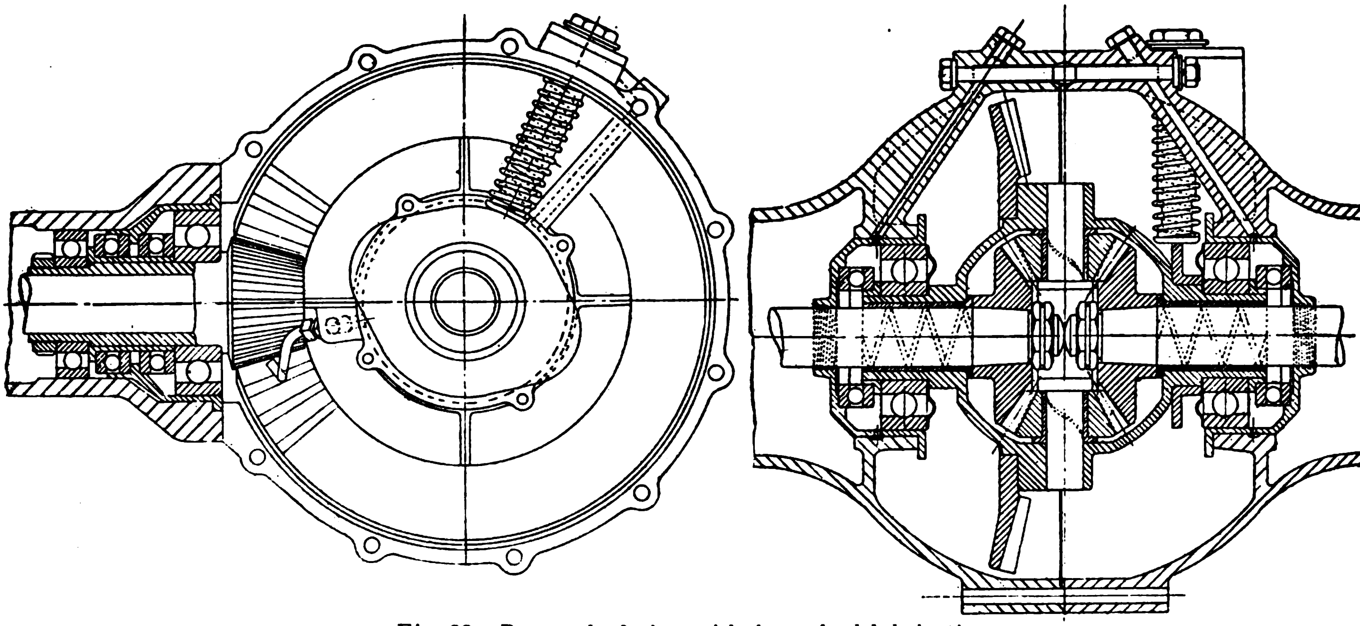

Fig. 22—Rear axle design with force feed lubrication

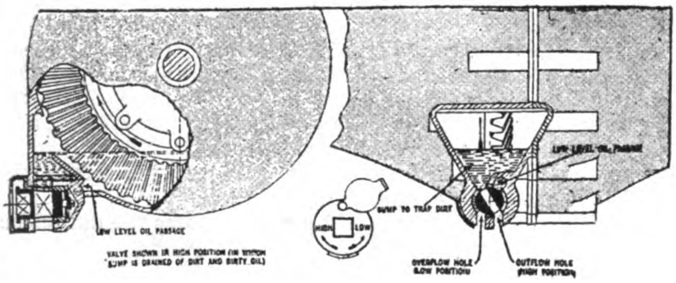

Fig. 23—Splash lubrication of Fergus rear axle

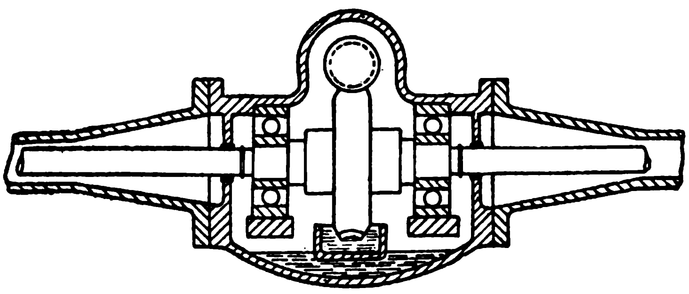

Fig. 24—Trough system of rear axle lubrication

already mentioned, and renders the lubrication of these important parts automatic, has met with a considerable measure of success. In this case the oil is retained in the ball and socket joint by the use of an oil-resisting fabric washer, which is so made that it is compressible to allow for angular changes in the relation to the ball and the rod.

It has also been suggested that the steering-box should be attached to, and be in communication with, the engine crankcase, whereby it would receive copious lubrication by splash. The author considers that there are more reasons against adopting this construction than there are in favor of it; with care the bearings and the worm gear can be efficiently lubricated by providing a removable plug of ample size so arranged that the casing can be well filled.

IV. Suspension

Various methods have been suggested for lubricating the leaves of the road springs. Normally, they come from the makers having had a mixture of graphite and oil put between the leaves before they are bolted up. This lubricant lasts them for a few hundred miles, when, if it is desired to renew it, it is necessary to jack the frame of the car up so as to take the load off the spring leaves, and, by means of a chisel or screwdriver, to pry the leaves apart and introduce fresh lubricant between them with the blade of a palette knife. It can be easily understood that, as this is a long and dirty operation, it is practically never done. One well-known maker, recognizing this to be the case, rusts the blades of his springs before he fits them to his vehicles, the assumption being that they will then give as easy suspension at the end of the car's life as they will at the beginning.

Other methods have also been proposed, namely, the fitting of perforated zinc or other non-ferrous metal strips between the leaves, the perforations being used to hold lubricant, while one concern supplies a graphite impregnated fabric for the same purpose.

The method recommended by the author (Fig. 26) is to cover the whole of the spring with a stocking made of grease-proof fabric, and to attach this, in the case of a cantilever spring, to an oil-tight casing placed round the trunnion of the spring, and, at the forward end, to an oil-tight casing which carries the shackle pin, roller, or whatever the method of attachment at that part may be.

The casings are then filled with oil, and can be left, with the certainty that no further trouble will be experienced from the springs until the oil has been used up—a matter of 10,000 miles or more.

A rather crude method of enclosing the springs is reproduced in Fig. 27 from an illustration in *The Automobile Engineer* of July, 1918.

For cheaper constructions, we have the half-elliptic leaf springs bolted direct to the frame and the axle as in the "Stellite," "N. E. G." "Humberette," and several other pre-war cars of the cheaper class, while in America a variety of springs have been made and tested with the ends so designed that all the flexion is taken by the spring, thereby dispensing with the shackles themselves and the consequent number of joints. A few examples are illustrated by Fig. 28.

In the author's opinion, this is far too important a point for reliance to be placed on the occasional turn of a grease cup, for, on examining one or two well-known makes, it will be found that the load on these pins reaches somewhere between 250 and 500 lb. per sq. in., and, in nine cases out of ten, the grease hole and groove are situated on the loaded side of the bearing!

Oil-less Bearings—It would be improper to leave this subject without some description of a type of bearing which does not require lubrication as it is understood in the ordinary sense. The author refers to those bearings which are generically called "oil-less bearings." They are of several kinds, the most usual being a bronze shell in which a spiral groove has been cut, subsequently to be filled with graphite under pressure, illustrated in Fig. 29.

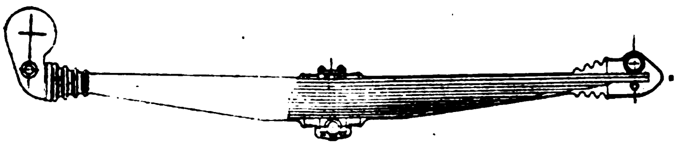

Fig. 26—Grease casing for body spring

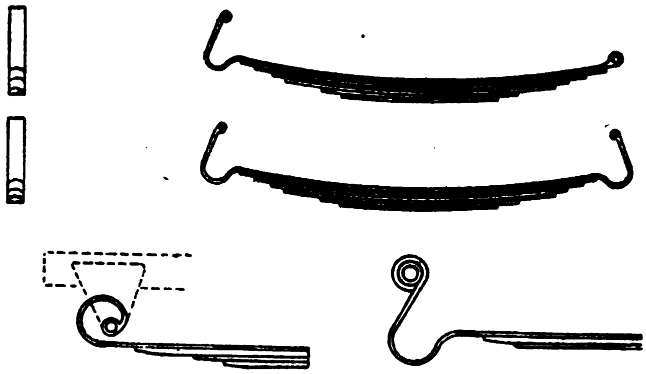

Fig. 28—Types of chassis springs with rigid connections

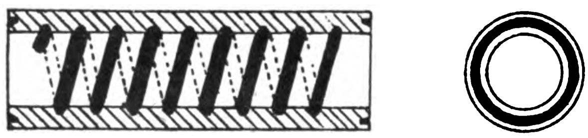

Fig. 29—Oil-less bushing

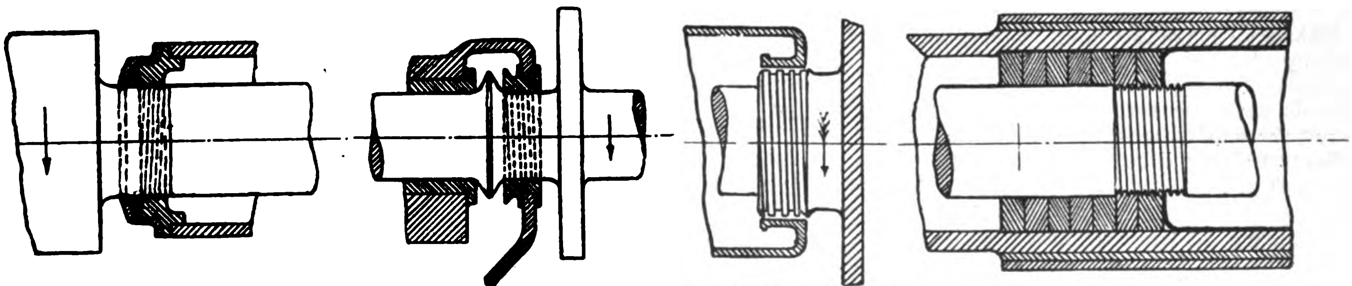
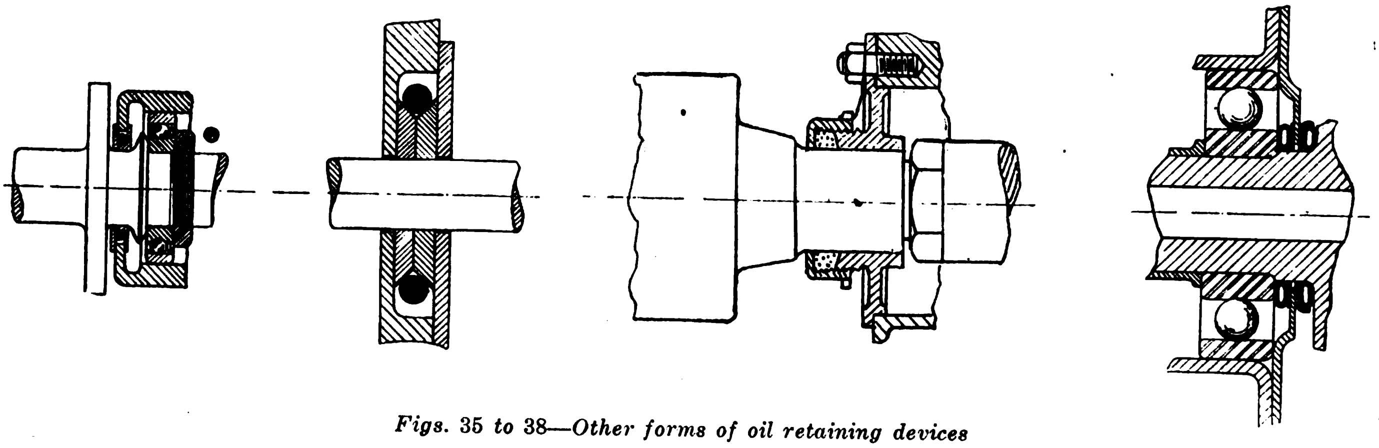


Figs. 31 to 34—Oil retaining devices



Figs. 35 *to* 38—*Other forms of oil retaining devices*

The author recently had an opportunity of investigating a very ingenious example of this type of bearing which is fitted to the "Marmon" car. The essential feature of this bearing is the provision of an inner and outer steel shell, between which is a lining of wire woven asbestos fabric which has been impregnated with graphite. The inner member of this bearing is dowelled to prevent it turning upon the pin or shaft, while the outer casing is forced into the boss of the bracket or lever. These bearings are used throughout the "Marmon" car for such parts as the spring shackles, brake levers, pedals, and the like.

V. Road Wheel Bearings

The well-known method of filling the hub with grease by fully loading the hub cap and then screwing it home, and so forcing grease into the bearing is open to improvement, as by this means only a small proportion of the grease is ever used. Fig. 30 shows a method favored by the author applied to the front hubs, from which it will be seen that one filling of oil will serve to lubricate the swivel pin and the hub bearings. Similar provision is also made on the "Fergus" and "Marmon" cars; one charge should last for a considerable period if proper measures are taken to prevent leakages. The same remarks apply to the bearings of the rear hubs, except that it is possible to lubricate these from the live axle supply, one method already having been mentioned.

VI. The Necessity for Efficient Retaining Devices

We cannot discuss methods of lubrication without devoting some time to the importance of suitably retaining the oil, and at the same time excluding the dust and water, which in many cases have largely contributed to the rapid destruction of ball and roller bearings. In almost any repair shop are to be seen numbers of racers worn and corroded beyond hope.

The best retainer in places to which water cannot have access and which are above the level of a body of lubricant, such as the ends of the crankshaft, the cam-shaft, or the gear-box main shaft, is undoubtedly the screw-thread, but the form of this is a matter which is open to discussion. Types now in use are shown by Figs. 31 and 34, and they all seem to be equally effective; the spiral groove cut in the stationary member works quite as well as the revolving screw on the shaft.

This is an important point, as it often happens that the revolving shaft or wheel-boss is so highly stressed that the addition of a screw-retaining thread could not be incorporated without seriously weakening the part; or, if the part itself is not threaded, dispensing with the necessary loose threaded collar, which could be fitted if room permitted.

Fig 34 is a type of retainer used on the "Marmon" car for the back axle, and is interesting inasmuch as the screw is an ordinary Whitworth thread with a more rounded top, and is distinct from other types in that it revolves in the felt washers without clearance.

The scope of these types of retainer is, however, limited. They cannot be applied to the hubs of road wheels, for instance, because of—

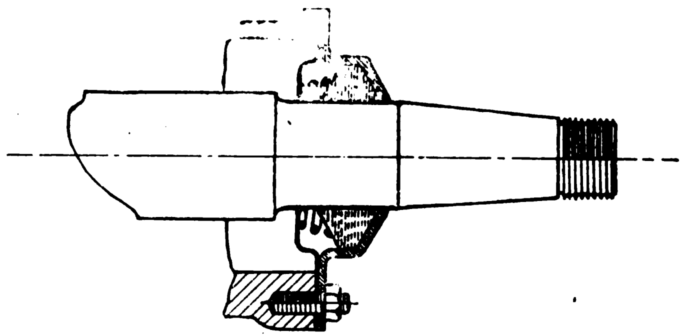


Fig. 39—*Fergus gland packing*

(1) Risk of water entering when the car is reversed or being washed;

(2) Admission of moist air when the car is laid up;

(3) Liability of leakage when the wheels are stationary and the hubs filled with a thin lubricant.

The hubs of the front wheels particularly are in so exposed a position that in dirty weather the steering heads are literally covered with water and mud, while, when washing the car, the centre of the hub receives copious supplies of water under pressure from the hose.

For these two reasons alone, therefore, the very best provision for retaining the lubricant is a necessity.

In the back hub it is equally important, as, although usually protected by the brake drum and cover, the lubricant must not be allowed to leak on to the brake mechanism.

Various devices are illustrated in Figs. 35-37, while Fig. 38 shows a new form favored by the author, which is of simple construction and easy to renew, and which will be capable of serving its proper purpose.

The type shown by Fig. 37, which is really a gland packing capable of adjustment from time to time, is not ideal, as, when tight enough to exclude oil, the friction on the shaft is of no small moment, while the chance of its being properly attended to is somewhat remote, as, in the author's opinion, it may be in such an inaccessible position that it is very seldom noticed, and is in any case a too frequent and complicated operation for most owner-drivers to undertake.

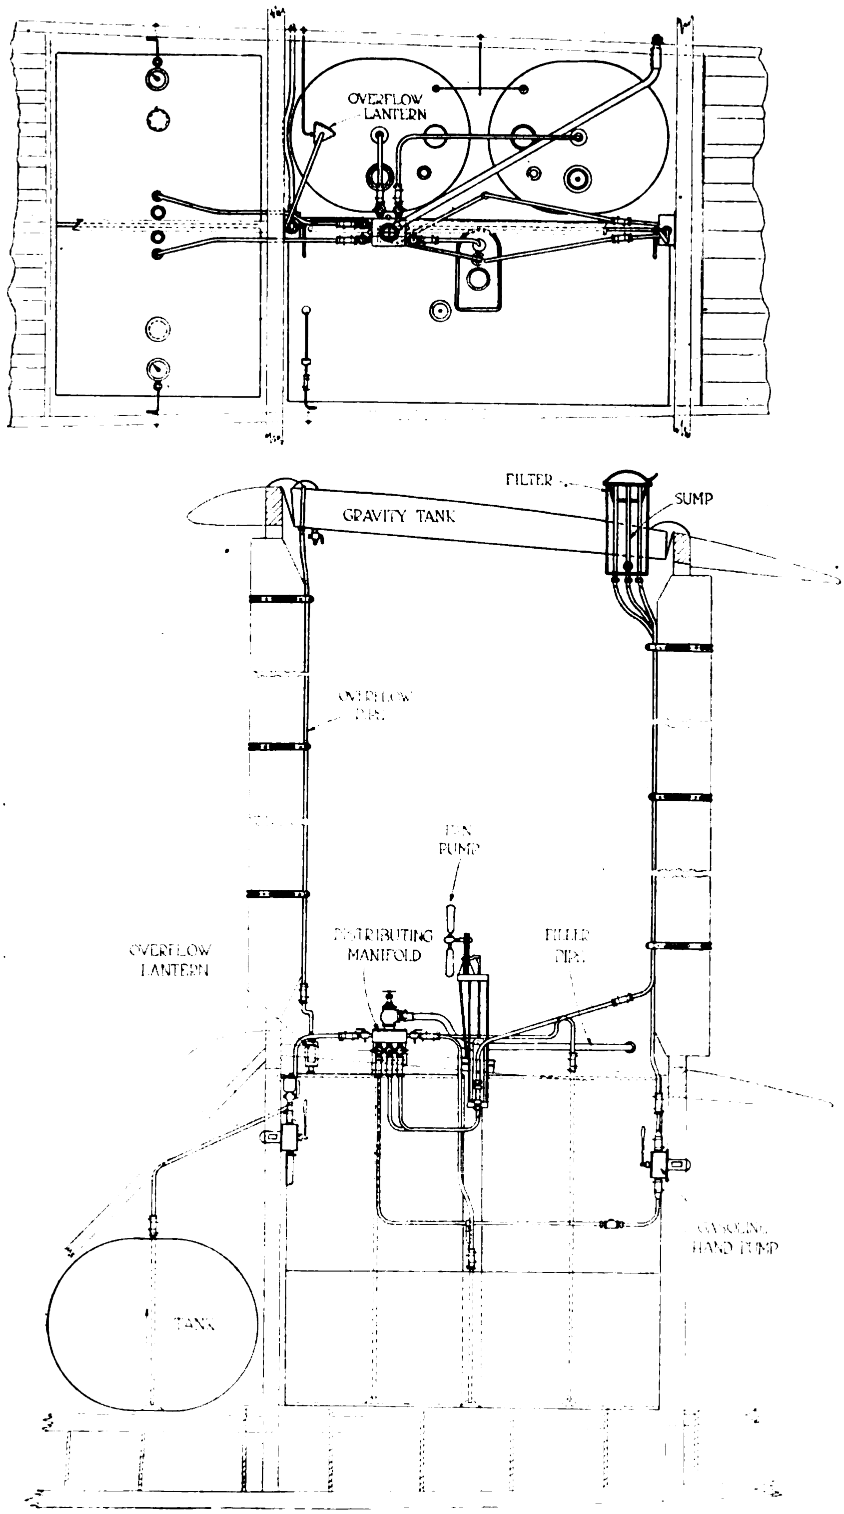
A much better method is employed on the Fergus car, and is illustrated by Fig. 39. This type provides for the wear of the packing ring, and does not grip the shaft too tightly; it has already been employed for the packing of oil and water pump glands on aero engines and is found to be thoroughly effective.

ALLOYS of iron with certain of the rarer metals are used to a great and increasing extent as a means of introducing these metals into steel, with a view either to removing oxygen from molten steel and securing sound castings or to securing special mechanical or other physical qualities in the steel. The manufacture of ferro-alloys is one of the principal electric furnace industries.

F-5-L Navy Flying Boat

Details of the Engine Mountings and Fuel and Oil Tanks—The Gasoline Supply System

Part III



Plan and elevation scale drawings showing the location and method of installation of the fuel tanks in the F-5-L Navy flying boat

By S. T. Williams
Assistant Chief Engineer, Naval Aircraft Factory, Philadelphia

SUMMARIZING the entire F-5-L flying boat, it was defined as a twin-motored tractor biplane, the engine being mounted at each side of the boat hull; the hull carrying the gasoline supply, crew and part of the ordnance. It was stated to have a wing span of 104 ft., a chord of 8 ft. and a boat hull 50 ft. long, the total flying weight being about 7 tons.

Two Liberty engines comprise the power plant. These engines are identical with the engines used by the army, with the exception of the pistons. The pistons are given more clearance, so that the compression pressure is reduced. The result is a slight reduction in maximum horsepower but greater engine life. This is advantageous because in seaplane service long patrols place a premium on dependability; and a seaplane does not habitually frequent high altitudes or require the maximum available horsepower.

In the main, the engine mounting differs only slightly from the mounting of the Liberty engines in the Curtiss H-12 and H-16 seaplanes. Horizontal laminated engine bearers are carried on wooden V-struts over each main wing hinge fitting, and are attached to the upper panel by tubular A-struts.

The radiator is carried on a bracket at the front, and the oil supply in streamlined tanks at each side of the bearers. However, in details, the F-5-L mounting is simplified, and made a better production proposition.

The first step was the elimination of drop forgings. Strap fittings built up and brazed together are used for attachment of bearers to V-braces, and the upper attachment of the A-brace to the engine section is also a strap fitting. This attachment is strong and simple. The ends of the tube are first fitted with a tubular sleeve, and then formed to a U-section.

In addition to the simplicity of construction, this end is extremely rigid. The A-braces are attached to the beam fitting through a universal joint bearing plate. This is also a built-up fitting.

The forward A-brace is bowed to clear the engine cylinders, and the halves are tied together by a cross tube and through bolt. This brace must be removed before the engine can be taken from the plane, and the removable cross tube and through bolt permit this to be done.

Differing from previous construction, the engine bearers are carried forward so that a straight radiator bracket may be used. Previously, the bearers were cut off by the

front engine flange and arched brackets used. However, the straight bracket is simpler to construct, and is possible on Liberty installations.

In an installation of this nature, it is, of course, impossible to start the engines by hand cranking on the propeller. For this reason a rear hand starter, comprising a reduction gear and clutch engaging the crankshaft, is used. One man can readily turn the engine over, though two are generally used.

As stated, the oil tanks are streamlined, cylindrical, and mounted at each side of the engine bearers. The total capacity per engine is 17 gal., and the two tanks are connected by a manifold, the division simply being constructional.

In later planes the side oil tanks are being superseded by one streamlined tank mounted between the engine bearers and behind the engines. This serves to clean the installation up to a marked extent.

A long-distance thermometer bulb is installed in the oil return line, and the gage is mounted in the mechanics' compartment by the tanks.

The oil pressure gage is installed on the pilots' instrument board. A water thermometer gage likewise is in the mechanics' cockpit. This location of the thermometers is because engine temperatures are of enough importance to demand quite frequent attention.

The gasoline supply is carried in five tanks placed amidships in the hull. There are two large cylindrical vertical tanks, one fore and aft horizontal tank, and two transverse horizontal tanks. The latter two were originally consolidated, but the single tank could not be removed without taking the plane to pieces. All have a total capacity of approximately 498 gal.

As these tanks are below carbureter level, a header or gravity tank is necessary. This is located in the upper wing, between the two engines, and carries about 20 gal.

The gasoline is pumped from the hull by a double-barreled windmill pump, and forced into the gravity tank sump. From this sump leads are taken to the two engines, and the surplus over this amount flows through small holes in the sump sides into the gravity tank.

Construction of Gravity Sump Noteworthy

When the gravity tank becomes full, an overflow pipe carries the excess back through a sight box into one of the tanks. And this overflow serves to show the mechanic that gasoline is being pumped and that the graviy tank is full.

The construction of the gravity sump is noteworthy. It will be noted that the base of the sump is somewhat below the bottom of the tank, and that the two are only connected through small holes at the sump sides. Hence if the gravity tank be shot away, the supply of gasoline pumped may be shut down to the amount used, with the base of the sump alone serving as a header tank.

A semi-rotary hand pump is used to fill the gravity tank when the windmill pumps are inoperative. This pump is an English design, and a similar pump is also used for bilge water.

The leads from all the supply tanks are consolidated into one manifold, and by regulating the valves gasoline may be pumped from any tank into the gravity tank. However, it all returns into the starboard forward vertical tank, and in flight gasoline is pumped alternately from this tank and each of the other tanks in rotation. It is necessary to pump from the tanks in rotation in order to trim ship and a separate manifold would be necessary to return the overflow gasoline to any tank.

Manifold Incorporates Filler Valve

It is to be noted that the manifold incorporates a filler valve piped to a union at the hull sides. This serves for the attachment of a pipe line from a supply boat or tank that the seaplane tanks may be filled by gasoline under pressure. Though this method of filling is not much used it is stated all the tanks may be filled thus in a few minutes whereas the funnel and measure method takes from a half to one hour.

There are few other points of interest in the gasoline system, standard sumps being used to prevent water and dirt from reaching the engine and dial gages being used on the tanks to show the gasoline supply at hand. Throughout the system all pipe line connections are through olive joints, and the features here are ease of connection, flexibility, and the fact that full flow of gasoline is permitted. As an aid to starting, a small hand primer permits raw gasoline to be pumped into the intake manifold.

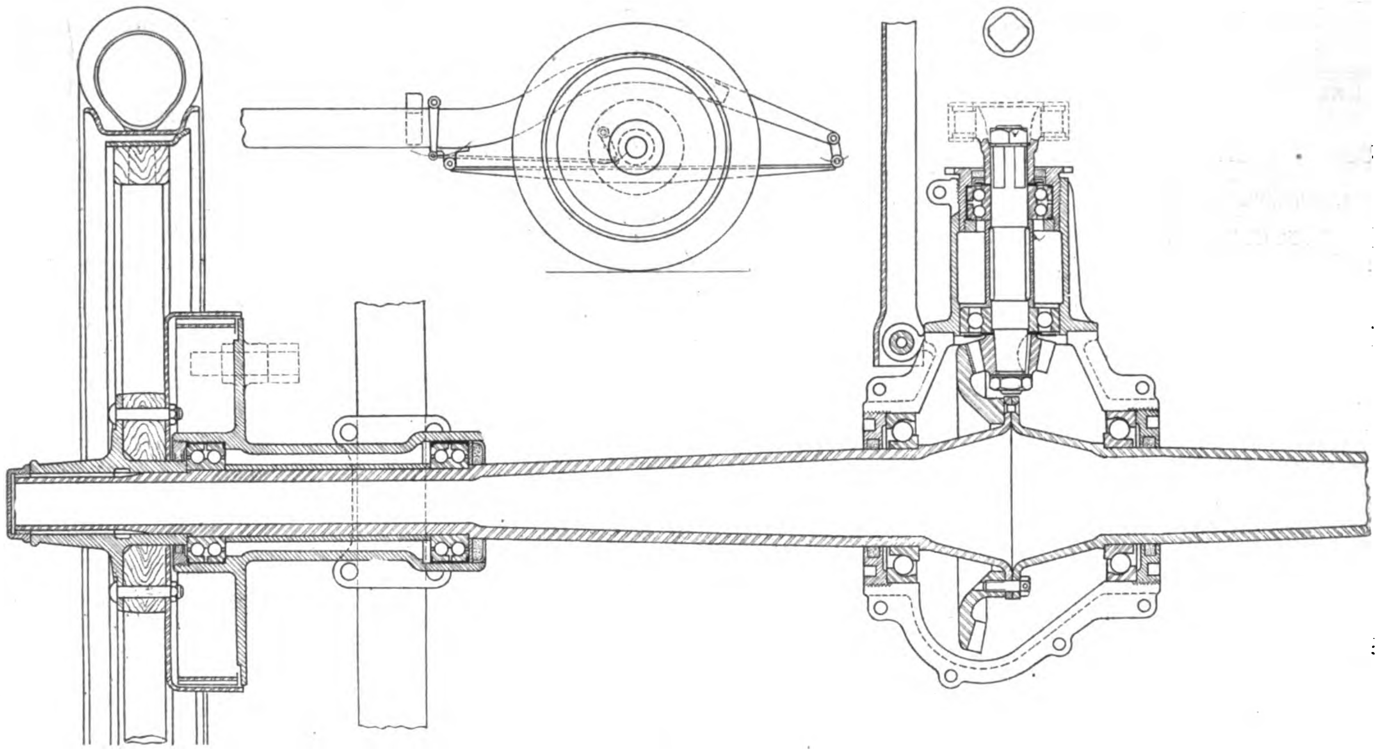
(*To be continued*)

Advocates Adoption of Metric System of Weights

THE adoption of the metric system of weights and measures is advocated by Harry Allcock in the *Bulletin* of the Federation of British Industries. He suggests that the Government should encourage the more widespread use of the international metric system both in the United Kingdom and in the British Empire generally by officially recommending all British manufacturers hereafter engaging in new industries, or introducing new standards into existing industries, to base their operations on the metric system on the distinct understanding that the Government will adopt that system as the sole legal system of weights and measures five years hence, or upon such later date as Parliament may then decide. He also suggests that the requirements of all Government departments should be specified in terms of the metric system wherever possible, and recommends other public and semi-public buyers to follow their lead in the national interest.

Kline Undivided Driving Axle

Is Built Without a Differential and Has Hollow Driving Shafts Which Also Serve as Carrying Members, Giving a Low Unsprung Weight



Section through Kline's solid driving axle

A RATHER interesting design of driving axle has been patented by Harmon J. Kline of Detroit, Mich. A sectional view of this axle is shown in the accompanying illustration. Mr. Kline's object in designing this axle was to produce a design that is relatively light in weight, inexpensive in construction and durable.

It has been proved in automobile racing that it is not necessary to employ a differential gear on a high speed car; under certain conditions of operation the differential is a positive detriment, as when one of the driving wheels stands on slippery ground, when it is impossible to obtain the necessary traction. The braking also becomes defective as the result of the differential action.

A tubular construction was adopted for the axle shaft in order to obtain an axle of maximum strength for a given weight. The great section modulus of the axle will enable it to easily withstand the strain due to the slight slippage of the wheels while turning corners.

The advantages of the low, unsprung weight are well known. A car having this feature will be easier riding, and will be less hard on the tires. Of course, the effect on the tires will be more or less neutralized by the increased wear due to slippage in turning corners.

An axle of this type would be most suitable for a speed car intended mainly for touring. Its low cost of construction would be a factor in its favor.

Steam Tractors in Germany

THE use of steam tractors and tractor wagons for the transport of heavy loads which came into favor in Germany during the war, owing to the shortage of motor trucks and fuel, has proved so satisfactory even in the most congested districts of Berlin that it is expected that that mode of transport will be used to an increasing extent after the war where rapidity of transport is not of great importance. Some relaxation of transport regulations, to which such tractor-trains are subject, will, of course, be necessary, owing to their weight exceeding 9 tons. A law and a decree exist according to which it is necessary for users of heavy road vehicles to obtain the permission of the authorities responsible for the maintenance of roads before such vehicles can be allowed to ply. It is suggested that the speed of steam tractors should be limited to 6 km. per hour, thus getting over the objections of the road authorities, who fear further increased maintenance expenses. The strengths of certain bridges would also have to be increased to bear the extra loads involved, and smoke and soot would have to be eliminated as far as possible. Coke has been used successfully for this type of tractor in Berlin.

Duration of Gas Explosion

C. A. NORMAN, in a paper read at the recent annual meeting of the American Society of Mechanical Engineers held in New York, in support of his opinion that combustion is not complete before expansion begins, said: "Clerk concludes from his experiments on an engine running at only 160 r.p.m. that some combustion is proceeding after the whole normal expansion stroke and whole intervening compression stroke. All experiments with closed vessels show gas explosions to take certainly not less than one-fortieth of a second, and this with only rich mixtures. With normal mixtures it takes a much longer time than that to reach the maximum pressure. Turbulence accelerates combustion very much. Yet such direct experiments seem to show that with normal mixtures even a turbulent combustion would take quite one-fortieth of a second. That, however, is exactly the time occupied by the whole expansion stroke of an engine running at 1200 r.p.m. We have, then, absolutely no reason to assume that the combustion is complete before the expansion begins.

Industrial Training

A LITTLE over a year ago, when it was attempted to supply the Army's needs in carpenters, plumbers, electricians, machinists, etc., from the young men in the draft, it was found that the number of mechanics available was not half enough, and to make up for the deficiency the plan of giving instruction in the handicrafts at the different colleges and universities of the country was conceived and put into effect. The schedule called for the training of 90,000 men, each of whom was to be given two months' schooling. It is obvious that in this limited time it was impossible to impart to the soldier-students a variegated training, so it was decided to teach each set of men a certain well-defined subject, but to make them as nearly as possible perfect in that branch.

The experience with the young men in the draft discloses a defect in our educational system. We see to it that every child gets a common school education, and up to the age of 14 the educational needs of all are provided for. Then follows that important period in life from 14 to 18 years, when the boy is usually allowed to do as he pleases. Instead of looking ahead and endeavoring to get a sound training in some good vocation, he will select the job that pays the best or that seems to require the least exertion. Employers also often take a narrow view of the situation, endeavoring to obtain the most work out of the boys without giving them a chance to qualify themselves for something better in years to come.

In Continental Europe industrial training schools have been a regularly established institution for a great many years. All young men engaged in learning trades are required to attend industrial evening schools in which such subjects as geometry, mechanical drawing, commercial arithmetic, etc., are taught. England last year introduced a similar system and the United States is now the only great industrial power in which the training of young men in secondary industrial schools is practically unknown.

We have been trying, by the extreme division of labor, to minimize the need for skilled men and have achieved really remarkable results in this way, but in the case of an emergency like the late war the country would be in a much more secure position if it possessed a greater number of well-trained mechanics. Would it not add greatly to our national assets if, instead of allowing our boys beyond the grammar school age to while away their spare hours in idleness, we compelled them to attend classes in which are taught the practical subjects listed above?

Dual Rotation Engines

MOST prime movers comprise one major stationary and one major movable part, and the output of power per unit of weight or bulk depends greatly upon the speed of the moving part. What really counts is the speed of one part relative to the other, but as long as the one part is stationary this is the same as the absolute speed of the other part. Assuming the speed of the moving part to be limited by conditions of strength of materials, it follows that if both parts could move, in opposite directions, the power obtainable from an engine of given dimensions could be greatly increased.

This principle was first applied to electric automobile motors. The armature speed of an ordinary automobile motor is limited by the fact that a single step gear reduction to the rear wheels is usually desired, besides which the wear and tear at very high speeds is excessive. By mounting the field frame so it can rotate, the relative speed of armature and field poles—and hence the output—can be doubled without increasing the strain on the parts and without introducing difficulties in gear reduction. The armature is geared to one road wheel and the field to the other, and the incidental advantage is gained that no differential is required.

The same principle may be (and has been) applied to internal combustion engines. Indeed, after Sequin in France and Farwell in this country had developed the rotary cylinder engine it was a foregone conclu-

sion that before long some one would build an engine in which both the cylinders and the crankshaft rotated. Textbooks on aircraft engines mention a Burlat engine which is of this type, but little has been heard of this engine's practical performance. It is evidently a long step from the mere conception of the idea to its practical embodiment in successful form. But the war has also seen this idea carried to fruition, for during the latter stages of the struggle the Germans put into service a single seater with a Siemens & Halske dual rotation engine which for a 240-hp. engine has the remarkably low weight of 1.78 lb. per horsepower, besides which the fuel consumption is said to be little if any more than that of stationary cylinder aircraft engines.

In connection with the early dual rotation engines, it was planned to use double propellers, say a right-handed traction propeller and a left-handed pusher propeller. This plan, of course, does not work out well in the case of single-seater scout machines, and the Siemens & Halske has only a single propeller, which is secured to the revolving cylinder structure. There is a gear connection between the cylinder structure and the crankshaft, comprising a set of three bevel gears, two of them coaxial, which are keyed to the crankcase hub and the crankshaft respectively, and the third on a stationary shaft or stud, meshing with both of the others. The power of the rotating crankshaft is thus transmitted to the oppositely revolving crankcase through the bevel gearset.

It is quite possible that the successful application of the dual rotation principle will revive the vogue of the rotary aircraft engine. With this construction it is possible to use comparatively low absolute speeds, so that the centrifugal stresses and the gyroscopic effect of the engine on the plane can be kept down. In fact, the gyroscopic effect can be practically eliminated, owing to two sets of parts rotating in opposite directions. Owing to the high virtual speed, that is, the short period of time required to complete the cycle, the thermal efficiency is bettered. With all rotary engines the churning of air is a serious source of power loss and with low speed of rotation this will be lessened. Finally, low speed tends to increase propeller efficiency.

The chief objection to the rotary engine in aircraft work so far has been its uneconomical use of fuel. This probably was due to the peculiar cycle employed and can hardly have any direct connection with the rotary principle. Since air cooling permits of, and in fact compels, the use of higher cylinder temperatures, it should be possible to overcome this handicap.

Tractor Development Threatened by Legislation

DURING the early period of automobile development a great deal of restrictive legislation was passed which considerably hampered the popularization of the new means of locomotion. It now looks as though a similar flood of tractor legislation was about due. There will be this difference, however, that whereas automobile legislation sought to regulate the use of the machines, tractor legislation will be so drafted as to control their sale.

Committee to Pass on Makes

In Nebraska legislation is proposed whereby a committee to be appointed from the Faculty of Agriculture of the State University is to be given power to determine which tractors shall and which shall not be allowed to be sold in the State. This would be an entirely new departure in legislative interference in business. The farmer buys a lot of other machinery besides tractors, such as binders, threshers, hay loaders, etc., and, if our memory serves us, no legislation has ever been adopted to appoint committees to pass on the worth of different makes of these machines. All these different classes of farm machinery had to pass through a development stage, when they were far from perfect. This stage unfortunately cannot be eliminated by legislative action. As the saying goes, a child has to crawl before it can walk, and so with new types of farm machinery: The best possible use has to be made of them while they are being developed.

Probably the argument will be made that the farmer should be protected against unscrupulous manufacturers who offer a product that is not up to the standard of the times and who do not stand behind it with adequate service facilities. The answer is that the best protection that can be given is that resulting from the system of selling through local agents. The farmer does not buy his tractor by mail from a catalogue house but from a nearby dealer, which latter often also sells automobiles and farm implements.

If a dealer in selecting his line picks a poor machine, or if he falls down on his repair service, the news will soon spread over the whole neighborhood and give him a serious set-back, if it does not ruin his business. Therefore, the dealer has very much at stake in making connections, and we believe the farmers' interests are safer in his hands than in the hands of a committee with no personal responsibility but with all the power of the State Government behind it.

To Compel Parts Service

Another thing which it is proposed to regulate by law is the maintenance of a parts supply in the state. While it is possible to compel manufacturers to maintain stocks of parts as long as they are selling tractors in the state, the chief difficulty in the past has been due to unsound manufacturing concerns going into bankruptcy and leaving customers with orphan machines on their hands. Now, it is quite conceivable that firms having the official sanction would fail in business, and the paternalism of the State would then prove of little avail to the farmer.

Latest News of the

10% Duty in France on European Cars and 45% on American

Congress of Automobile Manufacturers, Representing America, France, Belgium, England and Italy, Decides in Favor of Stiff Tariff—Attempt at Secrecy Badly Received

PARIS, March 10—A European import duty of 10 per cent against all European cars and a 45 per cent import duty in all European countries against American automobiles was the decision arrived at in the Congress of Automobile Manufacturers representing America, France, England, Italy and Belgium which met in Paris this week.

The Congress also voted that the Paris show would be held in the Grand Palais during the month of October, the London show in November, Brussels show in December, New York in January, and Chicago in February, as published in AUTOMOTIVE INDUSTRIES, March 27, page 721.

Before the war there existed a Union of Recognized Automobile Manufacturers' Associations. Germany and Austria were members of this Union. America was never invited to take any part in it. Its headquarters were in Paris, and the general secretary was Henri Cézanne, who is also secretary of the French Automobile Manufacturers' Association. It is impossible to hold a meeting of this Union without inviting Germany and Austria, and as there is no intention of entering into negotiations with these enemy countries, the union is being allowed to die a natural death.

45 Per Cent Duty on American Cars

On the other hand, it was necessary that there should be an exchange of views between the automobile manufacturers of Allied countries. The French manufacturers' association, therefore, invited delegates from England, Belgium, Italy and America to a meeting to be held in Paris. The American delegate was C. C. Hanch, representing the National Automobile Chamber of Commerce. It was this meeting which voted 45 per cent import duties throughout Europe against America, while retaining a 10 per cent duty among European countries.

A well-organized attempt was made to prevent any of the decisions of this congress reaching the press. While the proceedings were in progress not an atom of news was allowed to leak out.

When the congress came to a close an official communication was made to the press, but this had obviously been written with a view to hide the truth. Gradually the news leaked out, and finally, 3 days after the closing of the Congress, a French journal, *L'Echo des Sports*, revealed the whole proceedings. This attempt to put a cloak of mystery around the meeting has been very badly received in France.

As the outcome of this meeting a permanent Bureau of Inter-allied Automobile Manufacturers has been created. The American representative on this Bureau is the National Automobile Chamber of Commerce; France is represented by the Chambre Syndicale des Constructeurs d'Automobiles; England, by the Society of Motor Manufacturers & Trades; Belgium, by the Chambre Syndicale de l'Automobile de Belgique, and Italy by the Union Italienne, of which Engineer Marchesi, of the Fiat Co., is president. It is to be noted that this is the first time the American Automobile industry has been officially recognized by European manufacturers.

Mr. Hanch, who attended the meeting on behalf of the National Automobile Chamber of Commerce, refused to make any statement regarding the proceedings. He said that he had been sent over as the official delegate of the Chamber, and while in Europe intended to visit the leading automobile factories of France, Italy and England.

L'Echo des Sports, an independent French paper, has protested in strong language against the decisions of the Congress. It maintains that the importance of America as an automobile exporting nation is decreasing. In 1910, it declares, America exported 11 per cent of its automobile production; this dropped to 10 per cent in 1911, 8 per cent in 1912, 6 per cent in 1913, and 4 per cent for the first 6 months of 1914. All the European countries are automobile exporters. Thus, during the year 1913-1914 France exported 44 per cent of her automobile production, Italy 71 per cent, England 52 per cent, and Belgium 38 per cent. Protectionism, declares this paper, will ruin France.

France Favors 45 Per Cent Duty

PARIS, March 14—America has the reputation of being the home of yellow journalism, but the Hearst papers have been outmatched entirely by the Parisian journal *L'Echo des Sports*. When the Inter-allied Congress of Automobile Manufacturers was held in Paris last week all the business papers were annoyed at being unable to get anything more than a brief official summary of the proceedings. It was known that the question of import duties had been discussed, but no real information on this matter was issued.

Three days after the closing of the Congress *L'Echo des Sports* came out with what it claimed was a complete report of the proceedings. It maintained that the Congress had voted in favor of 10 per cent import duties in all European countries against European cars, and 45 per cent in the same countries against American cars. It now appears that this information was substantially correct, although no actual vote was taken.

The information was printed in such a way that it appeared to have been given out by C. C. Hanch, delegate of the N. A. C. C. now in France. Further, *L'Echo des Sports* hinted that it and Mr. Hanch were the only ones in possession of certain statistics regarding European and American exports. It also declared very proudly that on the day after the meeting Mr. Hanch sent a cable to Southerland E. Taylor, export manager of the Studebaker Corp., expressing his satisfaction at the vote taken by the Congress on this matter.

The facts are that there is no such person connected with the Studebaker Corp., that Mr. Hanch sent no telegram to the United States, and that he gave no information to any member of the press. All the information given by *L'Echo des Sports* with regard to Mr. Hanch originated in the fertile brain of the *Echo des Sports* reporter.

Automotive Industries

Ten French Firms in Union

No Competition in Models—Will Pool Purchases and Manufacture

PARIS, March 14—Ten French automobile manufacturers have formed a union to make their purchases in common, thus getting the advantage of lower rates; to standardize many parts of their cars, to avond direct competition by the production of similar models, and to produce a joint cheap car. The ten firms involved are Delage, Darracq, Clement-Bayard, Unic, Aries, Charron Limited, Delahaye, Brasier, Chenard-Walcker and Lorraine-Dietrich.

While the war was in progress it was suggested that the French manufacturers should co-operate through their national association in order to avoid direct competition, and get the advantage of standardization of parts. After negotiations had been carried out, it was realized that the entire trade was too big for real co-operation. As a consequence, the initiative was taken by Louis Delage to get together a group of manufacturers who would reveal their plans to one another, and who would co-operate toward standardization and low cost of production. The ten firms forming this group are all, roughly, of the same financial and engineering importance. The biggest does not employ more than 6000 workers, and the smallest has a staff of 2000. They do not all aim at producing the same type of car; indeed, one of the objects of the union is to prevent this, but they all do good engineering work.

One of the first results of this union is that no firm will build more than two models, and, as far as possible, each one will endeavor to avoid coming into direct competition with the type of car built by another member of the union. In order to make this possible, the members agree to put their plans before the union, and in case of dispute to submit to arbitration. An engineer who was formerly with Delahaye has been appointed general engineer for the union, and will work on questions of standardization and records for all ten firms.

An immediate benefit is expected to be obtained by pooling purchases of raw materials, for these ten firms are collectively equal in importance to the largest single automobile firm in France. The next almost immediate advantage is that no two of these firms will produce exactly the same type and same priced car. Where it is impossible to avoid competition there will not be more than two in any one class.

Advantages from standardization will be a little longer in coming. It has already been decided, however, that these ten manufacturers will reduce tire sizes to four. The union is now working on the standardization of electric equipment, size and type of battery, size of bolts and nuts, size of brake liners, size of steering wheels, gasoline connections, magneto bases and couplings, body dimensions and fittings, etc. There is no intention of stultifying design. Every manufacturer will be free to follow his own plans, but will at all times endeavor to work with the standards of the union.

It is quite possible that there will be a considerable exchange of finished material between these factories as work progresses. For instance, Delage now makes a piston of 88-mm. bore for a high-class 6-cylinder car. There is no reason why he should not also make the pistons for the Charron 4-cylinder car, which has the same bore. Another firm well equipped for cutting spiral bevel gears could very advantageously cut these gears for two or three other members of the group.

The buyer will be disposed to make his purchases inside this group when he realizes that most of the electrical equipment is the same for the twenty cars built by these ten firms; when he realizes that fifteen out of twenty front springs are interchangeable, that most of the ball bearings are the same size and type, that a length of fan belting will be the same from whatever firm it is bought; in a word, that he has the stocks of ten dealers at his disposal instead of one.

The designs are being worked out in common, with a view to low cost of production, and it is understood that each firm shall build the part for which it is best fitted. There will be a separate assembly plant and selling organization.

Former Ford Assistant Chief Engineer Allied with Chief

Special Telegram

DETROIT, April 3—Charles Mongana, Jr., who resigned as junior assistant chief engineer of the Ford Motor Co. this week, has associated himself with his former chief, C. Harold Wills, who resigned his position as chief engineer of the company two weeks ago. It is said that Mr. Wills left the Ford organization to bring out a new car. He will neither confirm nor deny this report, but states that he will remain in the automotive business. He has opened an office in the Book Building. Mr. Mongana was with the company for seven years, and during the war was in charge of its Liberty engine operations.

A. M. Wible, who has been connected with the Ford engineering department for some time, succeeds C. Mongana.

Natural Gas Recovery Increasing Rapidly

Multiplied 28 Times in 6 Years—Solution of Fuel Problem Indicated

WASHINGTON, March 31—The recovery of gasoline from natural gas is increasing and has attained special importance as a potential solution of the gasoline problem, according to John Dean Northrop, chief of the Petroleum Division of the U. S. Geological Survey, Department of the Interior. In a pamphlet discussing this subject, Northrop states that although the recovery of gasoline from natural gas is an industry scarcely a dozen years old, still in process of growth, it has become a material contributor to the domestic supply of motor fuels. Following are excerpts from Northrop's pamphlet:

"In 1911, the first year for which statistics are available, 176 plants in nine states produced 7,425,839 gal. of raw gasoline from natural gas. In 1917, only 6 years later, 886 plants in twelve states produced 217,884,104 gal., a gain in that brief period of 403 per cent in the number of plants and of 2834 per cent in the annual output of raw gasoline.

"Prior to 1916 the greater portion of the gasoline recovered from natural gas was obtained from casing-head gas, oil-well gas, or 'wet' natural gas by methods involving compression and condensation. Much of the output came, of course, from plants specially designed and installed to recover the gasoline vapors carried by gas of that type, but a fair proportion, particularly in the Appalachian oil field, was recovered incidentally by the use of simple and relatively inexpensive condensing apparatus, connected with vacuum pumps installed to expedite the production of oil, and some was recovered as drips from gas transmission lines.

"Since 1913, however, a steadily increasing proportion of the annual output of natural-gas gasoline has been recovered by the absorption process. With the scope of the industry broadened to include practically every type of natural gas found in the United States, its growth since 1913 has been in the direction of increased capacity for production of gasoline rather than in a direction that would tend to determine what other products could be derived from natural gas by variations in the methods employed to recover gasoline."

Discussing the industry further with relation to the production in the United States, Northrop stated that the year 1917 was one of marked expansion. "The quantity of raw gasoline recovered from

natural gas in that year," states Northrop, "including that produced by compression, by absorption, and by vacuum pumps, as well as that saved as drips from gas mains, was 217,884,104 gal., a gain of 114,391,415 gal., or 111 per cent, over the output in 1916. Of this quantity 168,866,555 gal., or 77.5 per cent, was recovered by compression and by vacuum pumps and the remaining 49,017,549 gal., or 22.5 per cent, by absorption and by salvage from gas mains. The combined gasoline obtained by compression and by vacuum pumps was greater than in 1916 by 83,943,768 gal., or 99 per cent, and the gasoline obtained by absorption and from drips was greater by 30,447,647 gal., or 164 per cent.

300,000,000 Gallons in 1917

"The quantity of commercial gasoline represented by the raw gasoline in 1917, though not susceptible of accurate determination, probably amounted to more than 300,000,000 gal.

"The average price received in 1917 for the raw gasoline at the sources of production was 18.45 cents a gal., and the market value of the entire output was $40,188,956, a gain of 4.6 cents in average unit selling price and of $25,857,808, or 180 per cent, in gross market value, compared with 1916, which reflects the steadily appreciating value of motor fuels in the period under review.

Gasoline Recovering Plants Increase

"The volume of natural gas from which the natural-gas gasoline was recovered in 1917 amounted to about 492,000,000,000 cu. ft., and the average recovery of gasoline per 1000 cu. ft. by all methods was about half a gallon.

"The number of plants, including vacuum-pump plants, recovering gasoline from natural gas increased from 596 at the beginning of 1917 to 886 at the end of that year, a gain of 49 per cent, and the combined daily capacity of all plants increased during the same period from 495,448 gal. to 902,385 gal., or about 82 per cent."

The analysis of the natural-gas gasoline industry by states is indicated in the table below:

All Aerial Activities Under One Head

Director to Have Charge of Training, Supply, Administration and Information.

WASHINGTON, March 31—Army aerial activities will be co-ordinated under one head by the Director of the Air Service. The reorganization is designed to supersede the dual wartime air establishment and to develop peacetime activities. Major-General Charles T. Menoher, Director of Air Service, has assumed full charge of all the aerial activities. He has appointed an executive organization under Col. M. F. Davis, who in turn has divided the duties of the various branches into four groups, as follows: (1) Training and Operations; (2) Supply; (3) Executive and Administrative, and (4) Information, Publication and Statistics.

The Chief of the Supply Group has charge of the supplies, airplane engineering, production, procurement, inspection, maintenance and finance disbursement for the entire Air Service, including both the old branches—Aircraft Production and Military Aeronautics.

The Chief of the Information Group gathers and distributes all information, statistics and publicity. In wartime he would have charge of intelligence work for the whole Air Service.

The Chief of the Training and Operations Group directs all training and operations.

The Chief of the Administrative Group is practically the Adjutant-General of the Air Service, controlling administration and executive work, personnel, office management, the medical section, cables, correspondence, etc.

Brigadier-General William Mitchell assumed charge of Training and Operations. Colonel William E. Gilmore became Chief of Supply. Lieutenant-Colonel William F. Pearson assumed charge of Administration and Major Horace M. Hickam became Chief of Information. It is to be noted that the Supply, Administration and Information Groups exist practically for the creation and maintenance of the Training and Operation Group. The latter has at its head the ranking officer of the branch chiefs—Brigadier-General Mitchell.

Each branch chief is directly responsible to the Director of the Air Service, and in this manner the activities of the entire service are co-ordinated in and centered upon the office of the Director.

Following the overseas divisional system, the Director has designated the Supply Group as first in the organization, Information as second, Training and Operations as third, and Administration as fourth. This does not imply rank. Each chief is immediately responsible to the Director. The Director designates what action is to be taken, lays down service policies and co-ordinates the activities of all four branches.

The primary purpose of this organization is to develop the Air Service, cooperate in the advancement of commercial aeronautics, and promote the principle that the United States deserves a leading place in the air, promised by our original application of the principles of mechanical flight.

Saxon Reorganization Plan Goes Through

DETROIT, April 3—At the moment of going to press word has been received that the advisory committee handling Saxon affairs will meet immediately and declare the present stock forfeited and reorganize, according to the plan already outlined in the March 20 issue of AUTOMOTIVE INDUSTRIES. This step has been taken because of the apparent lack of interest of stockholders and the failure of repeated efforts to get them together. As already stated, this will virtually wipe out the $6,000,000 stock of the company, and will call for an issue of $2,000,000 in bonds, $1,500 000 preferred stock and $3,200,000 common. Creditors will receive common stock in return for their obligations. The committee will meet this week either here or at Chicago to take action necessary to authorize the reorganization.

The reorganization of the company will not affect production operations. The plant is turning out between 40 and 60 cars daily and orders are already two months ahead of production.

General Motors Capital Now $370,000,000

DETROIT, March 31—The General Motors Corp., Wilmington, Del., has taken out papers at Lansing showing an increase in capitalization from $102,600,000 to $370,000,000. The Michigan Crank Shaft Co. of Muskegon has increased its capital from $50,000 to $200,000. The Union Tire Co., Detroit, has been organized with a capitalization of $100,000. The Moto-Meter Co. of Long Island City has incorporated its Michigan branch company, with headquarters in Detroit. Capitalization figures are $75,000. The T. W. D. Tractor Co. has been formed in St. Clair and incorporated for $100,000.

Program for Foreign Trade Convention

To Take Up Every Phase of Foreign Trade on April 24, 25 and 26.

NEW YORK, April 3—The complete program is now ready for the Foreign Trade Convention which is to be held in Chicago, April 24, 25 and 26. The convention is to take up every phase of foreign trade, and includes such well-known experts as James A. Farrell, Hugh Frayne, Eugene Meyer, Jr., P. S. Steenstrup and others. Following is the complete program:

THURSDAY, APRIL 24

Morning

Session Topic: America's Need of Foreign Trade.
The Effect of Increased Productive Capacity Upon Our Foreign Trade—Edward Prizer, president, Vacuum Oil Co.
America's Financial Equipment for Foreign Trade—Fred I. Kent, vice-president, Bankers Trust Co.
The Interest of Labor in Foreign Trade—Hugh Frayne, War Industries Board.
The Element of Labor Cost in American Exports—William Pigott, president, Seattle Car & Foundry Co.

Afternoon

The Vital Concern of Agriculture in Foreign Trade—Charles J. Brand, Chief of Bureau of Markets, U. S. Department of Agriculture.
The Mississippi Valley and Foreign Trade—John M. Parker, president, Mississippi Valley Association.
The Bargaining Tariff—Hon William S. Culbertson, U. S. Tariff Commission.
The Stabilizing Effect on American Industry of a Definite Foreign Trade Policy—J. W. Hook, president, Allied Machinery Co. of America.

Evening

Group I. Commercial Education for Foreign Trade.
Export Technique: Job Analysis of an Exporting House, Showing What Employees Should Know—D. E. Delgado, export manager, Eastman Kodak Co.
Cultural Equipment for Foreign Trade—John F. O'Hara, C.S.C., Notre Dame University.
Vocational Education for the Business of Exporting—R. S. MacElwee, assistant chief, Bureau of Foreign and Domestic Commerce.
Report of Foreign Trade Training Survey of U. S. Bureau of Education—Glen Levin Swiggett, specialist in Commercial Education, U. S. Bureau of Education.
Group II. Foreign Trade Merchandising.
America's Foreign Commerce and the Necessity for Co-operation of All Interests to Protect It—W. H. Douglas, president, Arkell & Douglas, Inc.
The American Foreign Trader — John F. Fowler, vice-president, W. R. Grace & Co.
Can American Fabricated Products Hold Foreign Markets?—Wm. E. Peck, president, W. E. Peck & Co.
The Mechanism of Foreign Trade—Wm. H. Knox, president, Wm. H. Konx & Co.
Group III. Financing Foreign Trade.
Financing Our Excess of Exports—Eugene Meyer, Jr., managing director, War Finance Corporation.
Acceptances in Foreign Trade—D. C. Wills, Federal Reserve Bank, Cleveland.
American Branch Banks Abroad—James H. Carter, vice-president, National City Bank.
Foreign Exchange—J. McCurrach, vice-president, Continental and Commercial National Bank.
Group IV. Advertising for Foreign Trade.
Survey and Method—F. A. Arnold, manager, Foreign Department, Frank Seaman, Inc.
Media—Stanley Resor, president, J. Walter Thomson Co.
Foreign Advertising Successes—W. G. Hildebrandt, Gotham Advertising Company.
Discussion—J. W. Helburn, Tanners Council of U. S. A.

FRIDAY, APRIL 25

Morning

Session Topic: The American Merchant Marine.
American Shipbuilding — Homer L. Ferguson, president, Newport News Shipbuilding and Drydock Company.
The World's Merchant Fleets To-day—W. S. Tower, Division of Planning and Statistics, U. S. Shipping Board.
The Future of the American Marine on the Pacific — Frederick J. Koster, president, San Francisco Chamber of Commerce.
The Relation of Law to the Development of Our Merchant Marine—Ernest J. Baldwin of the New York Bar.
The Relation of Inland Waterways to Foreign Trade—James E. Smith, president, Mississippi Valley Waterways Association.

Afternoon

Group V. Foreign Credits and Credit Information.
What Part Must Credit Play in the Expansion of Our Foreign Trade—E. D. Fisher, vice-president, Bank of Detroit.
Some of the Peculiar Difficulties and Problems in Foreign Credit Granting—F. D. Rock, credit manager, Armour & Co.
In What Form and Manner Can Exporters Co-operate for Developing Foreign Credit Information—H. F. Beebe, Winchester Repeating Arms Co.
What Assistance May the Government Give Exporters in Selecting Safe Foreign Credit Risks—E. E. Pratt, vice-president, Overseas Products Corporation.
Group VI. Direct Selling and Representation.
Direct Selling in Europe: Larger Nations, . . .; Smaller Nations, H. S. Demarest, general export manager, Green - Tweed Company.
Direct Selling in South America — P. S. Steenstrup, General Motors Export Company.
Direct Selling in the Orient — Howard E. Cole, Standard Oil Company of New York.
Direct Selling Through the Parcel Post—Maynard D. Howell, export manager, Montgomery Ward & Co.
Group VII. Export Combination—The Webb Law in Operation.
The Webb Law in Operation—John Walsh, chief counsel, Federal Trade Commission.

(*Continued on page* 768)

Big Gain in February's New York Exports

An Increase of More Than 60 Per Cent Over January Totals

NEW YORK, April 2—Although the new year started well with big figures for the month of January, February automotive exports from the port of New York show another substantial gain in number and value of cars and trucks and in value of parts.

Totalling the various items for January gives $4,274,827. The total for February is no less than $6,870,057, an increase of over 60 per cent. January exports of cars numbered 1047, valued at $1,480,-832; 515 trucks, valued at $1,604,418, were shipped, and the value of parts was represented by $1,189,577. The totals for the corresponding items for February are given at the foot of the table on this page.

Belgium appears as a purchaser again, after a long lapse, and business appears to be opening up with Turkey (both European and Asiatic). Both Japan and China show evidence of increasing business, and France has taken considerably more than half the truck total.

Earnings of Overland Set Record

To Concentrate on Small Four Poppet Valve and Medium-Price Knight Car

TOLEDO, April 2—The profits of the Willys-Overland Co. for the year ending Dec. 31, 1918, amounting to $11,510,645, were the largest in the history of the company. The net income after deducting all charges and taxes amounted to $5,536,254, which is equivalent, after paying preferred dividends, to $2.54 a share earned on the common stock as compared with $3.16 earned in 1917. The reduction is due to writing off $3,775,642 pending government settlements, and $1,000,000 from the investment in the Curtiss company.

The report states that all passenger car production had ceased on Nov. 1, 1918, and adds that the manufacturing plans for the coming year will be based upon a complete standardization of models and concentration on but two types. One of these will be the small four-cylinder car and the other will be a new Knight-engined car in the medium-price field. Following is the complete report:

Operating at 80 Per Cent War Basis

The express determination of the Willys-Overland Co. to shape its production program throughout 1918 to the winning of the war inevitably entailed the early acceptance on a large scale of a wide variety of Government contracts, the result being that on Nov. 11, when the armistice was signed, the company had on hand $75,000,000 of Government business. The factories were then operating on an 80 per cent war basis with 100 per cent set for the end of the year.

The cancellation of the bulk of the war work, which had involved the most radical factory adjustments, the creation of special departments, the changing over of equipment, and the preliminary expenditure of over $12,000,000 in preparation for the urgently desired large scale production, necessitated another sweeping readjustment to a normal peace basis. Its rapid and successful accomplishment has been a splendid tribute to the flexibility of the company's plants and organization.

All passenger car production had ceased Nov. 1, 1918. By Jan. 2, or within less than 50 days after "stop-work" instructions on war contracts, we were again turning out automobiles and by Jan. 31 were shipping 315 cars daily. At the present time 425 cars are being turned out daily, in accordance with a schedule calling for a steady increase in output to 1000 cars daily in August.

Notwithstanding the retarded start in automobile production caused by the delay in settling the status of the Government contracts, it is expected that the 1919 output will reach 175,000 cars, or over twice the war-depleted 1918 production, and exceeding by 25 per cent the company's best year. First hand reports of dealers and distributors evidence a steadily increasing demand for cars, each succeeding month of the new year having thus far recorded a striking gain in sales over the previous. In proportion to the supply, the demand for cars was probably never greater than to-day.

The manufacturing plans for the coming year represent a complete standardization of models and concentration upon but two types, viz.—a light four-cylinder car for the low-priced field, and a new Knight-engined car for the medium field. The elimination of the superfluous types will permit of production commensurate with the company's plant capacity and through the lowering of manufacturing costs will result in increased profits. Consolidation of manufacturing in two models for the principal selling fields will further entrench the company in its position in the industry.

In September, 1918, the company, anticipating, regardless of war or peace, an almost unlimited demand for tractors in an age of power farming, acquired the control of the Moline Plow Co., manufacturers of agricultural implements and of the Moline Universal tractor. The purchase enabled the immediate application of our immense plant facilities and large scale production methods to a proven tractor, and afforded the best and quickest way to attain a lead in this manufacturing field.

The Moline Plow Co. output this year will be double and in 1920 doubled again. Its acquisition has resulted in the permanent solidification and broadening of our production base.

Adjustments with the United States and British governments on war contracts are progressing somewhat slowly but satisfactorily.

The increase in the item of investments in and advances to other companies is represented mainly by the Moline Plow Co. common stock and by advances to subsidiaries.

Profits of $11,510,645 Greatest in History

The company's profits last year after allowance for taxes, $11,510,645, were the largest in its history, but it was felt that under present conditions conservatism should dictate their disposition. Accordingly deduction for depreciation, accruing renewals and tool replacements has been made to the extent of $3,775,642. In addition it was deemed wise to write off, pending Government settlements, $1,000,000 from the investment in the Curtiss Aeroplane & Motor Corporation.

The outlook for the automobile and the farm tractor industries was never brighter. With war conditions and restrictions past, I anticipate a year of activity and expansion. Both our production and financial programs, though conservative, have been made with this view in mind.

Another Rumor Dies

NEW YORK, April 3—To-day a rumor was afloat on Automobile Row that the parties who recently bought the Bosch Magneto Co. from the Alien Property Custodian had sold it, cleaning up $1,000,000. Inquiry at the Bosch factory in Springfield, Mass., brought forth smiles at the amount involved and indignation that the company should be the subject of such rumors. Sales Manager Alfred H. Bartsch stated that the factory is operating at capacity, that a dividend has just caused an increase of a couple of points in the stock and that there is absolutely nothing to the rumor.

Schumann Joins General Motors

NEW YORK, April 2—John J. Schumann, Jr., has accepted the position of assistant financial manager of the General Motors Acceptance Corp., the subsidiary of the General Motors group formed to finance its dealers. He was executive secretary of the distribution committee and assistant director of distribution of the Liberty Loan Committee for the Second Federal Reserve District, and his services with the Government loan organization are being volunteered by the corporation.

White Sales Increase 53 Per Cent in 1918

Profit and Loss Surplus Slightly Reduced, Due to Larger Federal Taxes

CLEVELAND, April 2—Gross sales of the White Motor Co. increased 53 per cent in the year ended Dec. 31, 1918, over sales for 1917, the increase being $13,810,348. After deducting Federal income, war and excess profits tax, the profits for the year were $6,380,585. A further deduction for Federal income, war and excess profits tax, estimated at $3,700,000, and dividends of $1,280,000, leaves a balance for the year 1918 of $1,400,585. This compares with $2,520,308 in 1917. The decrease is caused by the larger Federal taxes.

The annual report of the company points out that the financial condition at the end of the year was excellent. Production was, of course, largely influenced by the requirements of the war. In addition to a largely increased commercial demand, which, however, it was necessary to curtail because of the war, sales included 6451 trucks for the United States and French governments as against only 1358 trucks which were produced for war purposes in 1917.

The company has sold in all to the Allied nations, including the United States, nearly 18,000 trucks at a valuation of over $52,000,000. At the time the armistice was signed there were, in addition to these, 5700 trucks on order with a valuation of approximately $16,000,000, which were canceled.

Following is the consolidated income account of the White company and its subsidiaries for the year ended Dec. 31, 1918:

	1918	1917
Operating profit	*$5,947,494	$4,494,749
Other income	433,091	335,559
Total income	$6,380,585	$4,830,308
Federal taxes	3,700,000	1,030,000
Reserve	......	......
Balance	$2,680,585	$3,800,308
Dividends	1,280,000	1,280,000
Surplus	$1,400,585	$2,520,308
Previous surplus	5,216,301	2,541,041
Adjustments	4,590	154,951

U. S. Rubber Profits $16,072,042

Earnings Establish New Record—$30.81 on Common, Against $28.77 in 1917

NEW YORK, April 2—The U. S. Rubber Co. accumulated a net profit of $16,072,042 during the year ended Dec. 31, 1918, thereby establishing a new record in the history of the company. This profit is after the deduction of federal taxes, interest and dividends amounting to approximately $28,251,000 and is equal to $30.81 a share on the $36,000,000 of common stock as compared with $28.77 earned in 1917.

Sales increased from $176,159,694 in 1917 to $215,398,425, or $39,238,731. Net profits increased $1,731,465, and the surplus is $4,144,098 higher than it was in 1917.

In a statement accompanying the annual report, Col. Samuel B. Colt, chairman of the board of directors, says: "In refunding our indebtedness under our first and refunding mortgage, as set forth in the annual report presented March 20th, 1917, all outstanding issues were provided for at that time in cash except $9,000,000 of debentures of the General Rubber Co., which fell due December 1, 1918, and $2,600,000 of bonds of the Canadian Consolidated Rubber Co., Limited, which will fall due in 1946, for refunding which an equivalent amount of first and refunding mortgage bonds was reserved.

"Provision was this year made to take up the debentures of the General Rubber Co. when they fell due, through an issue of $6,000,000 of 7% five-year gold notes of this company, secured by $9,000,000 of our first and refunding mortgage bonds which were issuable for that purpose. The balance to take up those debentures was provided from our current resources.

"The financial condition of the company is strong, as indicated by the consolidated general balance sheet. With the continually expanding business and present high prices of materials, more working capital is required, in addition to which extensions have been planned, especially in the tire division, which will consume a large amount of money.

"Although the past year's earnings considered by themselves would warrant a dividend upon the common stock, your directors felt that it would not be prudent to pay one on account of the uncertainties which existed in business, and the company's cash position.

"Inventories of manufactured goods and materials have been taken on a conservative basis, having in mind the decline in values as a consequence of the closing of the war.

"The plants and properties have been maintained in the highest state of efficiency and adequate charges for depreciation have been made.

"The export sales outside of war orders were maintained during the year, and with the close of the war your directors believe there is a greater opportunity offered in this field than ever before and preparations are being made to materially extend our export business.

"The operating divisions of the company are now under the direct charge of the president. The president presides at the meetings of the operating council and reports their recommendations to the Executive Committee, of which body he is also a member. Greater directness and efficiency are thus obtained.

"The volume of business of our company so far this year has been somewhat in excess of the same period of last year, and though we look for a falling off in certain lines, especially those where war orders were large, now that we are on a peace basis, the present indications are that our volume for 1919 will be satisfactory."

The consolidated income account of the United States Rubber Co. for year ended Dec. 31, 1918, compares as follows:

	1918	1917	1916
Tot. sales..	$215,398,425	$176,159,694	$126,759,129

Lee Increases Directorate

NEW YORK, March 31—At the annual meeting of the Lee Rubber & Tire Corp. John M. Dettra, secretary of the company, was elected a director to fill the vacancy caused by the resignation of James W. Johnson. The retiring directors were re-elected. It was voted by the shareholders to increase the number of directors from nine to eleven, and J. C. De La Cour, vice-president and treasurer of the W. C. Schull Co., Camden, N. J., and H. C. Jones, president of the H. C. Jones Co., Conshohocken, Pa., will be added to the board as soon as the legal formalities are complied with.

John J. Watson, Jr., president, stated that the reason for increasing the board was that the management hoped to merge the Lee Tire & Rubber Co. of Pennsylvania, the operating company, and the Lee Rubber & Tire Corp. of New York, the holding concern, thereby eliminating duplication of accounts and also bringing about a saving on tax payments. Messrs. De La Cour and Jones are directors of the operating company.

The output of tires last year was 225,000 compared with 244,000 in 1917, and this year plans call for 250,000. According to the general manager, the labor situation has improved. The plant at present employs about 750 men.

Production Nearing Normal

Michigan-Ohio Plants Produced 5741 Cars Daily in March—4822 in February

DETROIT, April 1—Production in the States of Michigan and Ohio is approaching to near normal figures. During the month of March the daily output of 32 factories was 5741 passenger cars. This is a big gain over February, during which month 4822 automobiles were produced daily.

In the month of January, when the majority of the plants were just getting into commercial manufacture on greatly curtailed schedules, 2984 machines were built. The average daily production for the first quarter was 4467 cars.

Manufacturers are now beginning to talk in terms of annual production. A large number of the companies have drafted production schedules for 1919. Others, while outlining production for the year, are not making figures public.

This increase will be very noticeable during April. Packard will be in production. This company has put through its first car. Hudson will double its Hudson and Essex production. Buick hopes to attain the 600 daily production mark. Willys-Overland will be getting into production on its new light car. Oldsmobile and Reo propose big production increases. Studebaker is running up production approximately 40 per cent a month, while Ford will be hitting the 3000 mark. All the smaller concerns, many of them not in full swing as yet, will increase their output materially.

In 1918 car production figures were 1,044,754, as against 1,737,151 the previous year. In 1916 production was 1,493,617 cars. Normally the output increases at the rate of about 40 per cent a year. Had this rate prevailed last year the output would have been 2,750,000 cars, or more than double what it actually was. Because 90 per cent of the companies were on war work and started the year under a great handicap, many production experts declare remarkable results will have been obtained if 1919 figures exceed the 2,000,000 mark.

Some of the Detroit companies are having trouble getting material and parts. This is not true in all cases, but in a number of instances it is curtailing production. The trouble seems to be due to the inability of certain parts makers to get back into peace production.

Firms dealing with these concerns are therefore affected, while others are not. Lack of funds owing to unadjusted Government contracts and the unstability of the steel market are the big factors at the bottom of this trouble. The fixing of steel prices by the Government is now relieving this situation, as this market is gaining confidence again, even if the prices are a little high to suit the majority of the buyers.

For a few days following the fixing of the steel price by the Government the trade was uncertain and continued its

hand-to-mouth buying policies. Now, however, the companies are beginning to purchase steel in larger quantities. The immediate effect of the fixing of the price so far as the automotive industry is concerned was the stimulus it gave building operations. A number of plants have placed orders for structural steel and there is going to be a healthy increase in factory construction this summer.

Daily production figures for the first quarter of the year, together with the proposed annual output of Michigan and Ohio automobile plants, follow:

Car	Jan.	Feb.	March
Buick	100	400	450
Briscoe	30	50	50
Barley	..	4	10
Cadillac	55	60	80
Chalmers	30	65	70
Chandler	..	50	90
Chevrolet	..	300	350
Columbia	8	10	15
Dodge	300	375	400
Dort	40	65	70
Ford	1,300	2,000	2,400
Harroun	4	4	10
Hudson	30	50	50
Hupp	38	55	65
King	..	4	10
Liberty	15	15	25
Maxwell	150	150	220
Monroe	5	5	8
Oakland	160	160	200
Olympian	4	5	10
Oldsmobile	..	110	140
Overland	320	400	442

Saxon	10	50	65
Scripps-Booth	20	40	45
Studebaker	150	150	175
Essex	30	50	50
Grant	25	35	50
Total daily production	2,984	4,822	5,741

—

McFarland Back at His Desk

DETROIT, March 31—J. W. McFarland, purchasing agent of the American Auto Trimming Co., who has been at the Rock Island arsenal for some time in charge of purchases of leather and saddlery, has returned to Detroit and resumed his duties.

—

Program for Foreign Trade Convention

(*Continued from page* 765)

Forming an Export Association.
Discussion—William T. Nardin, American Canners' Export Association; E. E. Judd, American Webbing Manufacturers' Export Corporation; R. R. Fox, Simonds Mfg. Co.
Group VIII. Ocean Service.
Marine Insurance — Benjamin Rush, president, American Foreign Iuslrance Association.
Improved Port Service and Foreign Trade—R. A. C. Smith, New York.
Freight Forwarding for Export—W. J. Riley, export manager, Judson Freight Forwarding Company.
Inland Traffic Management for Export— Andrew Young, traffic manager, American Sheet & Tin Plate Company.

FRIDAY, APRIL 25

Banquet, Congress Hotel, Gold Room
The Relation of Diplomacy to Foreign Trade —Hon. Breckinridge Long, Third Assistant Secretary of State.
The Meaning of Foreign Trade to the Middle West—Hon. Frank C. Lowden, Governor of Illinois.
American Maritime Policy—James A. Farrell, chairman National Foreign Trade Council.
The Future of Our Foreign Trade—Edward N. Hurley, chairman, U. S. Shipping Board.

SATURDAY, APRIL 26

Packing for Export—Captain H. R. Moody, Q. M. C., U. S. A.

Industry Was Ready for 100% War Work

Fully Equipped on Jan. 1—Gain of 250 Per Cent in Orders in First Half of 1918

WASHINGTON, March 29—That the automotive industry was fully prepared to enter into an almost 100 per cent war program by Jan. 1, 1919, and had increased its war orders more than 250 per cent in the first 6 months of 1918, is shown in figures made public to-day by the Department of Commerce, which took a census last year of the steel and iron on hand, consumed and required by the automotive industry. This census was taken as a war measure.

The industry on Sept. 1, 1918, had on hand 288,819 tons of steel, not including 13,406 tons of scrap steel. The 590 concerns reported also that the consumption of steel from Jan. 1 to June 30, 1918, totaled 637,707 tons, of which 142,094 were used for government contracts. This does not include 41,371 tons of scrap iron and steel, of which 6225 tons were used for government orders. Requirements estimated for July 1 to Dec. 31, 1918, were placed at 627,137 tons, of which 356,422 tons were intended for government orders. In addition 38,764 tons of scrap iron and steel were needed, of which 25,783 were for government purposes.

The preparation for increased war work is consequently noticeable in the increase of steel for war purposes; 142,094 tons, 20 per cent of the total amount, was used in the first 6 months for war orders as being compared with 356,422 tons, 55 per cent of the total amount being estimated for war orders for the last half of the year.

—

Two New Caterpillars

PEORIA, March 31—The Holt Mfg. Co. has brought out two new Caterpillar farm tractors—one a 5-ton 4-plow machine and the other a 1-ton 8-plow machine. In general design they are practically the same as previous Caterpillar models, but have been slightly altered and refined as a consequence of the company's experience in building war automotive apparatus.

Both models show external evidence of military influence in their automobile style hoods. The seat is more comfortable and is located so as to give the driver a view both of the field ahead and of the work of his implements. The belt pulley is placed at the rear. The lubrication system has been improved.

The 4-plow model is equipped with a 4-cylinder modified Class B Liberty truck engine in which the bore and stroke are 4¾ x 6 in. Ignition is by high-tension magneto and lubrication by a pressure system through a drilled crankshaft with a bypass feed to the rocker arms and return to the crankcase; a standard type of centrifugal governor, fully inclosed and sealed, is fitted. Provision is made for mounting an electric lighting generator and starting motor. The Master clutch is a dry, multiple disk type, transmitting the drive through a standard 3-speed and reverse gearset of selective type. Drive is through a pair of bevel gears with two spur-gear reductions from the steering clutch to the track drive sprockets. There is no differential and steering is effected through steering clutches independently operating the tracks. Speeds are 1.3, 2.6, 4.9 m.p.h. ahead and 0.97 m.p.h. reverse.

The 8-plow machine has a 4-cylinder, vertical 6½ x 7-in. engine, all the other units being of similar design and differing only in size. Speeds are 1.35, 2.52, 3.88 m.p.h. ahead and 1.0 m.p.h. reverse. The overall length is 146 in. and the weight 18,600 lb. The overall length of the 5-ton machine is 124 in. and the weight 9400 lb.

—

Five Tractor Demonstrations in New York

ALBANY, N. Y., April 3—The State of New York is contemplating five tractor demonstrations during the coming season, all of which will be staged directly for tractor manufacturers and not for dealers and distributers as entrants. The exact dates of these demonstrations have not been scheduled as yet. The plan is to have 2-day demonstrations so that there will be one or perhaps more devoted to plowing and the second day for fitting. The two days will give a better opportunity of obtaining accurate records of performance than the acre or hour tests of last year.

The demonstrations will be divided over the State, with one for the western section, which probably will be in the vicinity of Batavia; one in the central will be held at Syracuse, and will have to be at the same time as the State Fair. This would not be so important a demonstration from the standpoint of performance but would be more in the nature of an exhibit. One would be in the eastern portion of the State, possibly in the area of Hudson; the fourth would be held in southern New York State in the vicinity of Elmira, and the fifth in the northern portion of the State in the zone of Malone or thereabouts.

The State of New York at present owns 70 tractors, and during the past winter established three repair depots, where these tractors were all overhauled. These were in Syracuse, Ithaca and Albany.

—

Restrictions Lifted on Canadian Imports

OTTAWA, ONT., March 29—Restrictions on the importation of automobiles into Canada have been lifted. It will be remembered that the Canadian Government, during the war, decreed that no cars for pleasure purposes that cost more than $1,250 should be imported into Canada. Later it was permissible to bring in a more expensive car under a special license granted by the government.

The War Trades Board of Canada has now approved a general license permitting the importation of all commodities restricted during the war except foodstuffs.

English Tractor Trials in Fall

To Be Held by Motor Mfrs. and Traders—Royal Agricultural Society Plans for 1920

LONDON, March 17—Recently the Royal Agricultural Society of England, the oldest body of the kind in the world, considered associating with the Society of Motor Manufacturers and Traders in promoting a trial of tractors and plows at a date suitable to British manufacturers on the resumption of their normal output after the cessation of war work. The R. A. S. E., however, demurred to the proposal of the tractor side of the trade—which in this instance largely represents imported or assembled tractors and plows—that the trial should be held this year, so the S. M. M. & T. decided to carry out a trial of its own. The event will be held next September in the neighborhood of Lincoln, one of the chief arable areas.

The R. A. S. E. notifies that it will organize trials of tractors and plows in the autumn of 1920, the date not yet being disclosed. There will be six classes of entries, four confined to internal combustion engines. In each class there will be awards of medals and cash prizes. There will be a class for tractors up to 30 hp. capable of plowing three 10 x 6 in. furrows, and another for more powerful tractors which will be required to plow four 10 x 8-in. furrows. There will also be a class for self-propelled plows of any power.

There is a separate class for direct-hauling steam tractors, and two classes for double-engine cable sets of the steam and internal combustion class respectively.

Resta Will Drive Sunbeam at Indianapolis

PARIS, March 22—Daria Resta, according to a statement from the Sunbeam factory at Wolverhampton, England, has taken up the exclusive agency for Sunbeam cars in America. He will drive the second Sunbeam at Indianapolis vacated by the death of Joseph Christiaens.

The accident which caused the death of Joseph Christiaens is almost inexplicable. Christiaens left the factory on the Indianapolis racer, and when 300 yards away, and on second gear, the car skidded, a tire burst and the machine swung right around. It charged a low wall and turned over, pinning Christiaens beneath it. Death was instantaneous. The steering gear of the car was found to be in perfect condition after the accident.

More Foreign Entries for Indianapolis

PARIS, March 14—Daria Resta will doubtless secure the Sunbeam car which should have been driven by Joseph Christaens at Indianapolis. The first car will remain in the hands of Jean Chassagne. There is a possibility of the Sunbeam company preparing a third car for this race. The name of the driver is not announced.

Arthur Duray is endeavoring to secure one of the Nagant Grand Prix racers which have been hidden away in Belgium for the last 4 years. These cars, which are on the Peugeot lines, were built for the 1914 French Grand Prix. They returned to Belgium after this race, and when war broke out they were so cleverly concealed that the Germans never were able to find them although they searched for them for 4 years.

André Boillot, the youngest and only surviving brother of Georges, will come to Indianapolis this year. Young Boillot counts on getting a 150 cu. in. Peugeot which is in the hands of private owners at the present time. This car is being worked on now, and if finished by April 15 Boillot will bring it to America and start in the Indianapolis race. With only half the cylindrical capacity of his rivals he has not much hope of winning first prize, but he believes that on a distance of 500 miles he can get within the prize money.

No Shows for Italy in 1919

TURIN, March 15—The Italian Automobile Manufacturers' Association has decided to hold no motor shows in Italy during 1919. This decision has been made to give every opportunity to the industry to get back from a war to a peace basis. It is probable, however, that the leading Italian makers will exhibit at the Paris and London shows to be held towards the end of the year.

Japanese Importer Studying Conditions Here and Abroad

NEW YORK, March 29—S. Umemura, of the Japanese automobile importing firm of Yanase & Co., Tokyo, Japan, has recently arrived in this country to make a study of automobile conditions here. Mr. Umemura will sail on April 5 on the *Aquitania* for England, and before returning he will also visit France, and, if possible, Germany. Yanase & Co. represent the General Motors Co. in Japan.

National Highway System for Japan

WASHINGTON, March 31—The Japanese Government plans a system of national highways to connect up all parts of the country. Two Japanese engineers, Mr. Makino and Mr. Zhalakeyma, have been sent to this country to study road administration, and are working with the Highways Industries Association. It is quite likely that Japan will create some form of national highway supervision and control similar to the Federal Highway Commission which is planned in this country under the Townsend bill.

Can Ship to Trinidad

WASHINGTON, March 31—Embargoes against the importation of automobiles, motor trucks and motorcycles into Trinidad and Tobago, West Indies, have been lifted, and these commodities may now be imported freely.

French Tractor Trial Entries

America, France and England Will Be Represented—Automobile Firms Demonstrating

PARIS, March 22—America, France and England will be represented at the official French tractor trials to be held at Saint-Germain, near Paris, from March 30 to April 6. The Ministry of Industrial Reconstruction and the French Agricultural Tractor Syndicate are jointly responsible for these trials, which, it is believed, will become the only official test of their kind to be held in France.

It is evident from the list of entries that European automobile firms are interesting themselves in the agricultural tractor, for, among the new machines to be demonstrated by automobile firms, are Renault, Delahaye, De Dion Bouton, Tourand-Latil, Schneider and Paris General Omnibus Co. The English participant is the Austin tractor, which was shown for the first time in France at the recent Lyons fair. Among the American machines are: Cleveland, Titan, Case, Avery, Moline, Fordson, Rip, American, Pidwell and Butterosi. In all sixty machines will take part.

Dirigible Service from Europe to Buenos Aires

WASHINGTON, March 31—Aerial traffic between Europe and Buenos Aires will be a reality within a few months when the Vickers Co. of London inaugurates a regular route between these two points by dirigible. It is expected that the airship will have a capacity for about 15 passengers, and will make the voyage in 6 days by way of Spain and Brazil.

U. S. Airplanes to Czechoslovaks

WASHINGTON, March 31—The sale of military airplanes and equipment, which was announced last week in AUTOMOTIVE INDUSTRIES, was a sale made by this government to the Czechoslovak military authorities of airplanes and airplane accessories, including $319,000 worth of planes and $600,000 worth of equipment.

The $319,000 worth of airplanes were 25 L. W. F. planes equipped with Sturtevant 5-A engines. The $600,000 worth of airplane equipment was 392,112 Chinese Dogmats (used for lining leather coats worn by aviators) sold to the H. E. Lazarus Co., New York.

Automobile Traffic of Central America

WASHINGTON, March 29—The selling of automobiles in Central America is limited by the absence of good roads, according to a report received by the Department of Commerce. Even in the capitals the streets are rough and the distances short, prohibiting increased use of cars. Consequently road building holds forth a promise for increased use of automobiles.

Manufacturers will be interested in three projects on foot in Guatemala and Nicaragua, which plan highway construction to facilitate automobile traffic between the cities of these two countries. One automobile company has obtained concession to transport freight and passengers, without competition, between Leon and Matagalea, Nicaragua, for the next 20 years.

Freight Rates to Far East Reduced

WASHINGTON, March 29—New and reduced rates on export traffic to China, Japan, Australia and the Philippine Islands, applying from Missouri River territory east through the Pacific Coast ports, have been issued by the United States Railroad Administration. Agricultural implements may now be shipped at $1 per 100 lb. Passenger cars and parts go at the rate of $3.75 and trucks and tractors at $3 per 100 lb.

German Automobile Business Dull

WASHINGTON, April 1—The cessation of army contracts has unfavorably affected the German automobile industry, according to reports received by the Department of Commerce. No cancellations of army truck contracts have taken place yet, so that this work may go on for several months, but the passenger car business and commercial truck business prospects appear gloomy, due to the great numbers of vehicles built during the war suitable to commercial and other use. Neutral countries indicate but a limited demand for German vehicles. There is a scarcity of bearing metal and lubricants.

Agriculture Machine Purchaser from Sweden

WASHINGTON, March 28—A buyer of harvesting and agricultural machinery is expected to arrive in this country from Sweden in April, as the representative of a concern with connections in Scandinavia, Finland, Russia, the Baltic Provinces and Holland. This information came to the Department of Commerce from the Swedish Chamber of Commerce of the United States, which has its office at the Produce Exchange, New York.

Disposition of War Material Abroad

WASHINGTON, March 31—Considerable war material, including tractors and trailers, will be disposed of abroad by the American Expeditionary Forces. A list made public to-day by the War Department shows the stock abroad includes 84 20-ton tractors, of which 7 have been returned to this country; 820 10-ton tractors, of which 112 have been returned, and 605 gun trailers and gun carriages, of which 93 have been returned. The remainder will be disposed of by the A. E. F. Contract cancellations to date include $240,000 worth of tanks, trucks and trailers, leaving $24,585,000 worth of orders still to be completed. Motor vehicles, accessories valued at $550, and oils, greases, etc., valued at $1,107.94, were reported this week by the Director of Sales.

France Retards Ford Dealers

Government Sells 5000 in Devastated Regions—Importers Dissatisfied with Duty

PARIS, March 22—French dealers of Ford cars have a grievance against the government. There are at the present time about 5000 cars ready for assembly at the Ford factory at Bordeaux. As the French government no longer requires these for military purposes, it was requested that the Ford company should be allowed to repurchase them and sell them privately. The French government would not permit this, but insisted on the cars being completed and delivered according to contract.

As soon as ready these cars are sold by the government to the big railroad companies of France, or to persons in the devastated regions who have urgent need of transportation. The dealers claim that this is illegal competition. The government, instead of using these cars for its own purposes, is acting as a dealer, and selling the cars to private concerns, thus robbing the legitimate and established dealers of their profit.

French importers of American cars are preparing a statement to be submitted to C. C. Hanch, representative of the National Automobile Chamber of Commerce, setting forth the hardships of their case. At the present time it is forbidden to import cars to France, although there is an urgent need of transportation. It is claimed that this prohibition is necessary in order to enable the French factories to return to peace conditions. It is pointed out, however, that the prices of cars are exceedingly high, largely owing to prohibited imports, and that many manufacturers are now in a position to make deliveries.

Just before prohibition was adopted the French levied a 70 per cent import duty. This worked very unjustly against American importers, for the 70 per cent was calculated, not on the invoice price of the car, but on the price of the car delivered in the French ports, thus including the original price, ocean freight and insurance. In some cases cars which cost 6,250 francs had to pay an import duty of 10,000 francs.

European manufacturers do not suffer from this to the same extent, for freight charges from either England, Switzerland or Italy are very low compared with ocean freight from America. It is understood that these facts are being laid before Mr. Hanch in order that he may bring them to the attention of the proper authorities.

Efficiency of Benzol Fuel

LONDON, ENGLAND, Feb. 26—The efficiency of benzol as a motor car fuel was well shown recently with an American coupé, which had been averaging 15 miles to the gallon of gasoline and which averaged 21 miles per gallon on benzol under practically identical conditions. The same car in the week's running around town is averaging between 19 and 20 miles per gallon on benzol. At present the price of benzol is artificially large and kept at the same level as gasoline, the only difference between the two being the 12 cents difference of the government license.

85,000,000 Bbl. of Gasoline Produced in 1918

WASHINGTON, March 29—Gasoline production in 1918 exceeded 85,000,000 bbl., an increase of 17,000,000 bbl. over 1917 production and 35,000,000 bbl. more than the production of 1916. The daily increase for 1918 was 47,000 bbl. above the 24-hour average of 1917. In 1916 there were 8,473,102 bbl. of gasoline sent abroad; in 1917 this amount increased to 9,901,877 bbl., while the 1918 exports reached a total of 13,312,508 bbl.

Gasoline Price War in South

NEW YORK, March 31—Certain parts of the South are at present in the throes of a gasoline war, which has brought the price of fuel down to 13 cents in Memphis. The battle was started when the Gulf Refining Co. cut its price 1 cent under Standard and other companies. Memphis has the lowest price, some other southern cities quoting as follows: Chattanooga, 16 cents; Knoxville, 18 cents, and New Orleans, 19 cents. It is anticipated that the war may reach to Baltimore, where the Gulf company is about to open headquarters. At present the cost is 22 cents.

Slow Methods Will Hamper Export Business

NEW YORK, April 1—A tire distributer in Manila complains about slow methods of some United States tire manufacturers, which is not going to accelerate export business. This distributer placed a number of orders with an American manufacturer. The orders included some items which had been increased in price, but the majority of items had not. Instead of filling the order with the exception of those items affected by a price increase the manufacturer held up the entire order. As it requires practically three months from the time of placing an order until the goods are received, the distributer was incensed at what he considered an unreasonable delay in the transaction.

Gear Manufacturers to Meet

CLEVELAND, April 2—The American Gear Manufacturers' Association will hold its annual convention here at the Hotel Statler, April 14, 15 and 16. The organization includes gear makers in the United States and Canada who are striving to develop means for standardizing their products. The coming convention will center its attention on this problem.

The following papers will be presented: "Gear Steels," by Dr. Parker, Carpenter Steel Co.; "Proper Sizes and Materials

for Gears;" "Worms and Worm Wheels," by a representative of the Timken-Detroit Axle Co.

The association officers are: President, F. W. Sinram, Van Dorn & Dutton Co., Cleveland; vice-president, H. E. Eberhardt, Newark Gear Cutting Machine Co., Newark, N. J.; secretary, Frank D. Hamlin, Earle Gear & Machine Co., Philadelphia; treasurer, Frank Horsburgh, Horsburgh & Scott Co., Cleveland.

Mexico Prohibits Oil Drilling

WASHINGTON, March 26—The Mexican Department of Industry has ordered foreign companies and individuals to refrain from drilling wells or any other wise developing the petroleum fields without permission of the Mexican government. The order reopens the many Mexican oil problems in which Great Britain, French and American companies are interested. The United States Department of State has begun a study of the order, and it is expected will soon take up the matter with Mexico.

High Freight Rates on Road Supplies Maintained

WASHINGTON, March 31—That the existing high freight rates for road construction materials will be maintained is evidenced in correspondence between the Highway Industries Association and the U. S. Railroad Administration. Protests were filed against the U. S. R. R. Administration plan, which will allow the reduction of freight rates on road building materials only if such are purchased by Federal, state or municipal agents, by the Highway Industries Association which pointed out that this would give very little relief. In reply the Director General of railroads stated that no reductions are now contemplated on the freight rates of materials for road building to be purchased by any other than the government, the states or municipalities.

Service Truck Putting Up Administration Building

WABASH, IND., March 29—An administration building to contain the offices of the company and to provide facilities for conventions and welfare work is being erected by the Service Motor Truck Co. The building, which will be three stories, 130 x 50 ft., fireproof and constructed of concrete and ivory finished brick, will cost about $100,000. The company expects to occupy it in July.

Airplane Competition for France

Engines Will Be Officially Tested in 1920 — Requirements and Specifications

PARIS, March 15—A big airplane and airplane engine competition will be organized by the French Government next year. It has been decided that there will be three types of engines:

a—125 to 150 h.p.
b—250 to 300 h.p.
c—500 to 600 h.p.

Each engine will have to run 300 consecutive hours at 80 per cent of its maximum power.

The maximum weight for the complete engine with water, gasoline and oil for 5 hours running is 6.6 lb. Propeller speed is limited to 800 r.p.m. It has been decided that in order to allow present engines to compete, they can be used with geared-down propellers, in order to obtain the limited number of 800 r.p.m.

The airplane conditions are:

a—Solidity with a coefficient of 6;
b—Excess power; theoretical ceiling 5000 ft.;
c—Minimum speed at 3280 ft.; 93 m.p.h.
d—Landing ability; practical conditions corresponding to a weight of 38 kgs. per square metre maximum (this is based on the fact that the lower the wind for a given area, the easier it is for the plane to land);
e—Security; Multi-engines. When three or four used, a single engine should be capable of maintaining the machine in the air.

Planes to Be Examined

Airplanes now under construction can be presented for examination as they are finished, but the final classification will not take place until 1920. In addition to this, there will be a big competition on a fixed date during the year 1920. It is stated that important orders will be placed for the successful machines, and all planes having obtained a satisfactory minimum number of points will receive an order sufficiently large to cover the cost of experiments.

U. S. Tractor Will Bring Out Uncle Sam

MENASHA, WIS., March 31—The U. S. Tractor & Machinery Co., organized with a capital stock of $250,000, is equipping the Strange building at 100-110 Tayco Street for a machine shop and assembling plant, pending the construction of the first unit of its permanent plant. The company will produce the Uncle Sam tractor, a 20-30 type designed by G. D. Harris, Chicago, who is the designer of the new company. H. C. Berry, chief engineer of the U. S. Tractor Co., Chicago, which is taken over by the new corporation, will hold the same position in the new organization.

Government Sells Non-Usable Vehicles

WASHINGTON, March 28—Request for bids on motor trucks and passenger cars made by the Zone Supplies and Storage Officers of Baltimore to the public this week has not been withdrawn because they did not state that the vehicles offered for sale were only scrap value and not usable. A proposal will be sent out by the War Department which will distinctly state that these vehicles are beyond repair and only good for scrap.

Export Licenses Valid Until Used

WASHINGTON, March 28—Export licenses which have been issued by the War Trade Board for Norway, Sweden, Denmark and European Holland, which by their terms are limited to a particular date, will be valid until used, notwithstanding that such licenses are stamped with the expiration date on them.

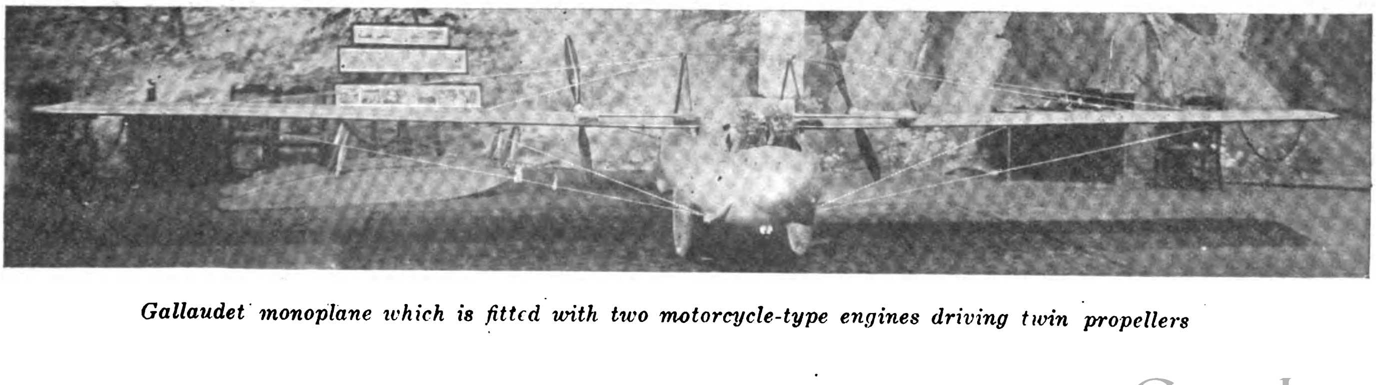
Swiss Aerial Passenger Service

WASHINGTON, March 29—An aerial passenger service between Zurich and St. Moritz, in Switzerland, is planned, a company being formed with capital stock of $96,500. The Swiss legislature announces itself in favor of the scheme. A flight between the two cities can be made in an hour and the fare will be $96.50 per person. These two towns are well known resorts frequented by tourists, and it is expected that they will patronize the air route.

Sell Condemned Army Trucks

WASHINGTON, March 31—Eighty trucks, touring cars and ambulances owned by the Army and which have been condemned as unserviceable will be sold to the highest bidders. These vehicles are at Canton, Md., and can be examined by application to Captain Wayman, 11th floor, Coco-Cola Building, Baltimore. Bids will be f.o.b. Canton, and bidders are expected to make full payment before the cars are delivered or shipped. Proposals should be accompanied by a certified check for 20 per cent of the amount of the maximum bid, and will be received up to April 4.

Included in the vehicles to be sold are: 2 Bourne, 2 Dodge touring, 1 Dodge



Gallaudet monoplane which is fitted with two motorcycle-type engines driving twin propellers

roadster, 1 Dodge patrol, 14 Ford touring cars and trucks, 2 G. M. C. ambulances, 1 Hupmobile touring, 1 International truck, 20 Kelly-Springfield trucks, 2 Liberty trucks, 1 Maxwell touring, 5 Overlands, 1 Peerless, 1 Reo, 1 Republic, 5 U. S. A. trucks, 5 White trucks, 1 Reo engine, 1 class B engine, 8 truck frames, 10 axles and housings, 1 class A transmission, 4 truck bodies, 2 trailers, 6 class B dashes and 2 truck seats.

Airplane Distribution of Parts for Service Trucks

WABASH, IND., March 29—Aerial distribution of repair parts to distributers and service stations for Service trucks has been instituted by the Service Motor Truck Co. It will be handled under contract with the Service Aviation Training & Transportation Co., a separate organization formed by stockholders of the Service Motor Truck Co. J. P. Porter, chief pilot, was formerly of the Royal Flying Corps and was one of the instructors at Love Field Aviation Camp, Texas. Assistant pilots are Harold C. Brooks and V. P. Hollingsworth. Oscar Bricker, formerly of Love Field, is in charge of the hangars and landing field. A 44-acre field has been prepared for landing. Curtiss JN-4 planes will be used.

Cleveland Co. Completes Experimental Cars

CLEVELAND, April 1—The Cleveland Automobile Co., recently organized by F. C. Chandler, J. V. Whitbeck and other Chandler officials, has completed its first experimental car. It is a 6-cylinder job with block-enclosed engine and 118 in. wheelbase. It is built to sell at approximately $1,200. The body is of the straight line type, 5-passenger capacity, with cellular radiator. The company is making its own axles but is using Timkin ball bearings. The ignition system is Gray-Davis battery type. The bore and stroke of the engine is 3 x 4¼.

Ellis-Smith Making Complete Products

ELMIRA, N. Y., March 31—The Ellis-Smith Mfg. Co., Inc., is now making its products from raw materials in its own foundry.

Ford Tractor Plants Springing Up

Production at Detroit and Hamilton Under Way—Eight Small Plants Along Rouge River

DETROIT, March 26—Henry Ford's latest tractor projects, both here and in Hamilton, O., are well under way. The Detroit establishment is now hitting volume production and work is progressing on eight smaller plants along the River Rouge. In Hamilton, O., contracts have been let and work commenced on a $1,000,000 tractor plant to be in operation in about a year.

The Hamilton plant will be operated by water power secured by damming the Miami River at that point. The units to go up first will be the power house, factory, dock and heating plant. Later warehouses and additional manufacturing units will be added. The capacity of the Hamilton plant will be 500 daily. The power plant will be 50 x 60 ft. The manufacturing plant, 100 x 700 ft., directly behind it, will be built of steel, concrete and brick. The dimensions of the loading dock are 30 x 400. The finished tractors will leave the plant under their own power and be driven to the loading dock and into the cars.

At Nankin, Mich., a few miles from Detroit, Ford is completing a small plant, consisting of a dam, power-house and factory. It will be in operation soon. At that time some parts departments from the present Fordson plant at Dearborn will be moved into the small establishment, and certain other parts will be made there.

A similar factory, only larger, is about to be built at Plymouth. Plans for the Plymouth plant are now being drafted. Work on a dam at that point is under way, and building operations will start soon. Each of these little factories will employ from 25 to 75 men.

Army Trucks for Hospital Use

WASHINGTON, March 31—The 1000 motor trucks which were recently turned over by the War Department, as announced in a past issue of AUTOMOTIVE INDUSTRIES, will be used for the transport of soldiers, sailors and marines between government hospitals. These trucks were transferred without charge to the Secretary of the Treasury, who directs the Public Health Service under Public Act No. 326, which authorizes such transfers and directs the Secretary of War to supply as many motor vehicles not required by the War Department as may be required by the Health Service.

Packard Now in Production

DETROIT, April 1—The Packard Motor Car Co. has completed its first passenger car since the war and expects to be in production by the first week of April, although earlier plans did not call for production until May. The last war truck has been completed and the government adjustment of canceled contracts is progressing rapidly.

Martin Co. Buys

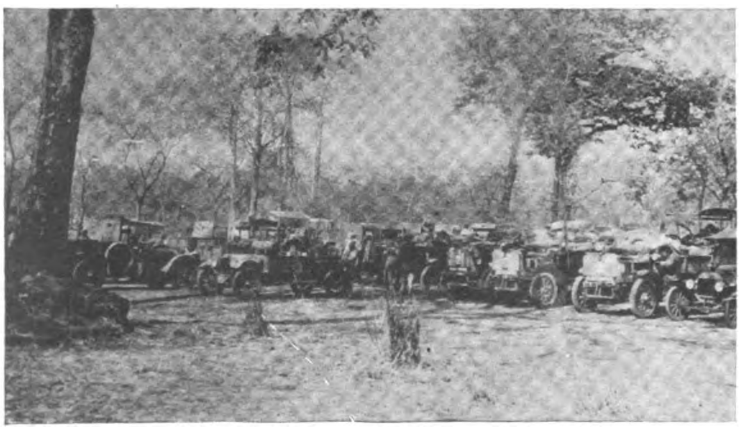
LANCASTER, OHIO, March 31—The Martin Mfg. Co. has purchased a 3-story building formerly occupied by the Wilson Mfg. Co. for $39,000.

Ford Considers D. C. Site

WASHINGTON, March 29 — Henry Ford & Son will give "due consideration" to Washington when they decide to build another factory, according to a letter received here to-day by the Chamber of Commerce from E. G. Liebold, secretary to Henry Ford. The letter was in response to a request by the Washington Chamber of Commerce urging Mr. Ford to locate his next plant here.

New Advance-Rumely Four-Wheeled Tractor

LAPORTE, IND., March 31—The Advance-Rumely Thresher Co. has developed a new small four-wheeled tractor which is quite similar to its older models, and which is designed to pull three 14-in. mold board plows or four disk plows. It is rated 12-20 hp. and follows standard Oil-Pull design and construction throughout. It has a slow-speed, two-cylinder, horizontal, heavy-duty engine, equipped



Left—Motor convoy in camp in Bush country, late German East Africa. Right—A frequent occurrence to motor transport in the swamp districts of German East Africa during the late campaign

with a Secor-Higgins carbureter burning kerosene, and has the usual oil cooling system and fanless radiator. All transmission gears are cut from forged steel blanks, and are thoroughly protected from dust and run in oil. Transmission shafts and axle are mounted in Hyatt roller bearings. The gearset provides forward speeds of 2.1 and 3.26 m.p.h. and reverse.

Maxwell-Chalmers Rumored Moving

DETROIT, March 31—Maxwell-Chalmers Motor Car Co. officials will neither confirm nor deny the story coming from Dayton that the company proposes to move its plant to this city. Dayton newspapers, however, declare such a deal is contemplated, and that the removal will be made within the next five weeks. The plants of the company in Dayton employ about 2500 men. It is also rumored that the Maxwell Motor Corp. plant at New Castle, Ind., also will be moved here. The New Castle plant employs 2500 men.

Pontiac Factory Destroyed by Fire

PONTIAC, MICH., March 28—The Hess Pontiac Spring & Axle Co., a unit of the Standard Parts Co., Cleveland, was destroyed by fire Monday night. The loss is $150,000, of which $90,000 is covered by insurance. The forge plant burned down. A new forging department will be built immediately. Approximately 150 men are out of work. The fire started from the explosion of an oil burner.

Aluminum Co. to Build Warehouse

DETROIT, April 1—The Aluminum Co. of America, which leases a warehouse here, is about to build one of its own. A 5-acre site in the northeastern factory district has been purchased and building will start soon.

Allied Industries Takes Over Star P. & V.

NEW YORK, March 31—The Allied Industries Corp., which is a manufacturers' representative, has taken over the business and agency lines formerly controlled by the Star P. & V. Corp. These include Gary truck, Fruehauf trailers, Esta water auxiliator and Federal tires.

Kelly-Springfield Doubles Stock

NEW YORK, April 2—Stockholders of the Kelly-Springfield Tire Co. have approved the proposal of the directors and authorized the increase of the common stock from $5,029,000 to $10,000,000. The increase is for the purpose of distributing common stock dividends at the rate of 3 per cent quarterly, beginning in May.

Edison Lowers Price of Batteries

ORANGE, N. J., April 2—The Edison Storage Battery Co. has reduced the price of types A, B and C Edison Cells about 16 per cent.

Merger Rumors Set Detroit Talking

Ford, General Motors, Maxwell-Chalmers and Standard Parts All Involved

DETROIT, March 28—This city is seething with merger rumors affecting the Ford Motor Co., General Motors, Standard Parts Co., and Maxwell-Chalmers Motor Car Co. These rumors are directly due to General Motors expansion projects. While 80 per cent must be discounted as street talk, there is sufficient evidence to convince automotive circles that transactions of magnitude are pending. In every instance, however, officials of the companies are busy issuing denials.

Rumor declares that General Motors is trying to gobble up the Ford interests in the Ford Motor Co. From a semi-authentic source it is learned that the Du Pont-Durant interests have made the Fords a cash offer for their holdings in this company. From another equally authentic source comes the declaration that Henry and Edsel Ford have no desire to dispose of their stock, and that the first announcement of their proposed withdrawal from the Ford company was a mistake.

A typical illustration of the type of rumors going around tells of a General Motors project to purchase the Ford stock in the Ford Motor Co. for $187,000,000 and to discontinue the manufacture of Ford cars entirely. In such event the plant would be used for the manufacture of Cadillac cars.

While no statement has been issued, it is certain, however, that General Motors is planning large expansion projects involving leading automotive concerns. It is a known fact that a consolidation of the Maxwell-Chalmers companies is being worked out with General Motors' financial aid. Details of this proposed merger have been published in New York and are generally known among Detroit brokers. For a financial consideration General Motors is to get possession of the common stock of Maxwell-Chalmers, and, while it might not take over the active management, the Maxwell-Chalmers organization would virtually become a General Motors unit.

Merger plans call for the organization of a new company to take over on an exchange of security basis, yet to be worked out, assets of the present Maxwell company. An effort is to be made to cancel the lease of the Chalmers, under which Maxwell is operating the former's plants, and take the Chalmers directly into the new Maxwell corporation. Some new cash capital would be supplied by General Motors. The proposed change in management is to be deferred until the end of the current fiscal year, July 31.

General Motors officials and officers of the Standard Parts Co. deny the report that the Durant interests are negotiating for the control of the Cleveland company. Absorption of Standard Parts, however, would give General Motors practically everything which goes into the manufacture of an automobile and place it in a great strategic position in the manufacturing field. United Motors Corp., which is a General Motors concern, is supplying ball and roller bearings, gears and transmissions, ignition systems, passenger car axles and engines. Control of Standard Parts would add truck axles, springs, rims, bearings, etc.

Changes on Staff of Motor Life

NEW YORK, March 31—C. B. Ames, business manager; C. G. Sinsabaugh, editor; A. B. Hunt, southern advertising manager, and W. W. Sheppard, western advertising manager, of *Motor*, have resigned their connection with that publication to become associated in similar capacities with *Motor Life*.

Sinsabaugh was with *Motor* for four years, previous to which he had been editor of *Motor Age*. Hunt, Ames and Sheppard were identified with *Motor* for approximately 12 years. A. J. Stocker, for many years with *Automobile Blue Books*, becomes middle western advertising manager of *Motor Life*. All five of these men will be engaged to some extent in work on the *Automobile Blue Books*, as well. Monte W. Sohn, former editor of *Motor Life*, leaves that post to assume the post of Director of Research and Publicity for *Motor Life*, *Automobile Blue Books* and *Automobile Trade Directory*.

Pilot McClelland in America

NEW YORK CITY, April 2—Pilot H. McClelland of the R. A. F., who gained the distinction of having piloted the Handley-Paige bombing plane from England to Salonica in July, 1917, arrived in America last week for a 2-months' visit. Pilot McClelland was a member of the independent bombing forces of Great Britain whose special work was to bomb industrial centers of the Rhine Valley.

Fair Association Buys Tractors

CHATTANOOGA, TENN., March 28—To help the tractor manufacturer get his product better known in the South and to get Southern farmers to see the opportunities and greater yields from power farming are the two reasons which have caused the Chattanooga Interstate Fair Association to buy two Case tractors for demonstration purposes. These tractors, a 10-18 and 10-23, will be delivered this week and immediately put to work on farms in the vicinity of Chattanooga. Hamilton County, in which this city is situated, has at present about twelve or thirteen tractors scattered through it. The plan of the association is to make the tractors self-supporting, so that when they are finally worn out there will be money to buy new ones.

The outline of the working schedule of these tractors is as follows: Two men have been hired as operators, and receive besides their daily wages a certain sum for every acre plowed, disked or harrowed. The machines will operate in different parts of the county. Each man

will carry his own fuel and supplies, as many of the farms in this section of the country do not carry these.

The men will pick their customers, who are to pay not more than $2.50 for haying the land turned, 75 cents for having it disked and a proportional sum for drag-harrowing. A minimum of 5 acres is to be worked, but many of the farmers working small tracts of land can club and thus get the minimum figure. It is very likely that tractors will be sold here in much the same way; that is, several farmers whose lands adjoin may purchase a tractor jointly, because singly their farms are too small to warrant buying a tractor.

The farmer whose land is being worked will board the tractor man. Two sizes of machines were chosen, so farmers can study the performances of both and pick ones suitable for their needs.

Stanley Develops Railway Car

BOSTON, April 2—The Gray & Davis Co. is now building units for the newly formed Unit Railway Car Co., Newton, Mass., which is building the Stanley railway car for use on lines of any road. This car was designed by the Stanleys, and when the motor car plant was taken over by the new company they retained the patents for the vehicle. The car is operated by a steam engine and uses kerosene or fuel oil in the burner. The engine is geared direct to the driving axle by a spur gear, and both units run in an oil bath in an oil-tight case.

Will Support Federal Highway Bill

WASHINGTON, March 31—That Senator Charles E. Townsend, who will probably be chairman of the Committee on Post Offices and Post Roads in the Senate, will support the highway commission bill was evidenced by a letter sent to the Rotary Club of Kalamazoo by Senator Townsend, in which he stated: "You may be certain that if I shall become chairman of the Committee on Post Offices and Post Roads in the Senate, I shall devote most conscientious attention to this great subject (the Federal highway commission bill), which is properly within that committee's jurisdiction."

Bour-Davis Car Made by Louisiana Car Co.

SHREVEPORT, LA., April 2—The Louisiana Motor Car Co. has taken over the production of the Bour-Davis car and is now putting through a run of 33 jobs, and will bring out also a 2-2½-ton truck. One hundred of these trucks are now going through. The company has been in existence for a year and in actual production for about 4 months, and has produced to date 24 cars and 2 trucks. W. F. French is general manager of the company, which is capitalized at $1,000,000 and headed by T. H. McGregor. Other officers are E. C. Rhodes, vice-president; factory manager and engineer, William Ross, and chief designer, A. L. Vargha.

Government Buys 14 Aviation Fields

Will Retain These and Six Balloon Stations—Will Release 11 Other Fields

WASHINGTON, March 31—The Government has purchased fourteen aviation fields and will retain six balloon and aviation fields that are already Government owned. Eleven aviation fields used during the war have been released. Following the announcement of this fact in a recent issue of AUTOMOTIVE INDUSTRIES, it can now be stated that the following fields are the ones to be purchased and released. Those being purchased are:

March field, Riverside, Cal.
Mather field, Sacramento, Cal.
Carlstrom field, Arcadia, Fla.
Dorr field, Arcadia, Fla.
Ellington field, Houston, Tex.
Kelly field No. 2, San Antonio, Tex.
Park field, Millington, Tenn.
Souther field, Americus, Ga.
Selfridge field, Mount Clements, Mich.
Chanute field, Rantoul, Ill.
Scott field, Belleville, Ill.
Balloon School, Arcadia, Cal.
Brooks field, San Antonio, Tex.
Engine and repair depot, Montgomery, Ala.

Under the same order the following fields will be released June 30, 1919:

Wilbur Wright field, Dayton, Ohio.
Taylor field, Montgomery, Ala.
Payne field, West Point, Miss.
Eberts field, Lonoke, Ark.
Gerstner field, Lake Charles, La.
Call field, Wichita Falls, Tex.
Taliaferro field, Hicks, Tex.
Carruthers field, Benbrook, Tex.
Barron field, Everman, Tex.
Love field, Dallas, Tex.
Rich field, Waco, Tex.

Further orders will define the policy regarding Chapman Field, Miami, Fla., and Hazelhurst and Mitchell fields at Mineola, Long Island.

It is understood that the following fields owned by the Government will be retained:

Army Balloon School, Fort Omaha, Neb.
Army Balloon School, Lee Hall, Va.
Kelly field No. 1, San Antonio, Tex.
Post field, Fort Sill, Okla.
Rockwell field, San Diego, Cal.
Langley field, Hampton, Va.

According to the Assistant Secretary of War, the Army Air Service will abandon Camp John Wise, San Antonio, Tex., and McCook Field, Dayton, Ohio.

The status of Bolling Field, Anacostia, D. C., has not been definitely decided.

Tarrytown Addition for Chevrolet

NEW YORK, April 2—The General Motors Corp., Chevrolet Division, has awarded the contract for the erection of a 3-story reinforced concrete enameling and assembling plant on its Tarrytown, N. Y., property. The building will be 220 x 80.

England Fears Foreign Competition

(*Continued from page* 738)

tion to question the legality of the Board of Trade's action in continuing to exclude goods now that the war is practically over, without the direct sanction of the legislature. It is, however, expected that a statement of policy on this matter will be made within the next fortnight. Up to the present it seems as if the State Department concerned is merely acting as an agent of manufacturers whose plea that their action is to protect labor from being unemployed, deceives no one who is acquainted with the past views of many of these persons, and who now fails to see any corresponding effort of theirs to resume their normal time productions. There seems to be some special favor being shown to the Ford interests in the matter, for it is admitted that quite a large number of parts have been permitted to be imported for that car—and the defense offered is the plea that two-thirds of the materials required had been made up here. Naturally many people in the trade are asking why it is not possible for them to get imported spares for cars of other makes and why all this special attention to Ford interests.

I now hear that the Morris Co. have fixed up a contract for engines with the Hotchkiss Co. at Coventry, but as this company is unknown here as builders of small car engines, some doubt exists as to the outcome of this deal. Writing of specialist engines and engine builders reminds me that a big fillip is being given to this side of the British industry, notably by the Tylor Co. of London and the Dorman Co. at Stafford, both these companies being out for mass production.

The Tylor company has a new large works still unfurnished where the engine for the Angus Sanderson car is being built. The Dorman Co. hitherto have been mostly associated with engines for trucks, but are now going to cater for the car and light car trades. They have one size of engine about being started on for a mass output of 12,000 sets to be retailed at $225 without magneto and carburetor. The pre-war corresponding figure for this engine would have been about $150.

This company also is about launching a scheme for getting private car owners interested in Dorman engines. It is proposed to list this special engine to garage men and repairers at a discount, and with special inducements to interest them in re-engining customers' cars. Blue prints and all particulars and brackets and lugs for attaching the engine will be offered ready for standard makes of cars, the necessary fittings being listed at practically cost price.

Olympia Show Nov. 7-15

LONDON, ENGLAND, March 20—The Society of Motor Manufacturers and Traders have definitely fixed the dates for the Olympia Motor Car Exhibition. These are Nov. 7-15 inclusive.

Briggs Leaves Wheeler-Schebler

NEW YORK CITY, April 2—George T. Briggs, for years sales manager of the Wheeler-Schebler Carbureter Co., Indianapolis, has resigned and associated himself with the Sinclair Refining Co., Chicago.

- Patent leveling, 25c. per 100 lb.
- Resquaring, 5 per cent of gage price after quality, finish and size extras have been added.

Seconds 10 per cent less than the invoice Pittsburgh price for corresponding primes.

Automobile Makers Buy British National Factory

THE first of fourteen large manufacturing plants erected by the British Government during the war has been disposed of by the Disposal Board, Land and Buildings Section. This is the National Aircraft Engine factory at Edmonton, which has been purchased by Straker-Squire, Ltd., for £140,000. It is stated that the original cost of construction was £133,000.

The factory is a new one, constructed within the last two years and comprises a splendid range of buildings of brick and glass, standing on a site of 14 acres. The works adjoin the Edmonton passenger station, and are well equipped with railway sidings.

The purchasers propose to transfer the whole of their manufacturing activities to Edmonton. Their program is to concentrate upon two standard models, a six-cylinder type of fast pleasure car and a four-cylinder commercial chassis suitable for transport work and motor omnibuses. The cars will be British-built throughout, and will be fitted with British magnetos. Almost all the engineering work and the whole of the body work will be completed on the premises. The entire factory will be organized on the lines of quantity production from standard jigs, and it is anticipated that 5000 work-people will be continuously employed. It is planned to produce 2000 complete vehicles the first year.

Hanch Visiting Foreign Factories

PARIS, March 14—C. C. Hanch, official delegate of the National Automobile Chamber of Commerce, left Paris to-day for Lyons and Turin. He attended the International Meeting of Allied Automobile Manufacturers called together by the French makers, and at which the formation of a permanent bureau was decided on. Mr. Hanch will spend 2 days at the Lyons fair and from there will proceed to Turin and Milan, to visit such factories as Fiat, Isotto-Fraschini, Lancia, Spa, Bianchi and Itala. On returning from Italy, he will spend a few days in the Paris district before leaving for England, where he expects to remain about a month, and will then sail for America.

—

Released Officers with Standard Parts

CLEVELAND, March 28—Several officers who left their positions with the Standard Parts Co. to go into government service have returned to civilian life and their pre-war work. Other officers identified with the engineering division of the Motor Transport Co. have also been added to the staff.

Capt. E. R. Finkenstaedt, formerly active in the production of the Liberty truck for the government at Washington, has resumed his duties as assistant to President Christian Girl. Major Lewis P. Kalb, until recently in charge of designing, testing and specification work in the engineering division of the Motor Transport Corps, has joined the engineering staff of the company as assistant director of engineering, and Capt. A. L. Watts, in charge of the specification and record section of the engineering division of the Motor Transport Corps, has also joined the engineering staff. Both Lieut. Rex Gosling, who before entering service was purchasing agent of the Standard Welding division, and Lieut. Ray Jones, who gave up his position as production manager of the Perfection Spring division to enlist in the navy, have returned to their respective plants.

—

V. K. McBride, formerly assistant sales manager of the Federal Motor Truck Co., has been appointed to a similar position with the Premier Motor Corp., Indianapolis.

—

Fred D. Rice, who has recently been released from service in the navy, is now representing the Hess Steel Corp., Baltimore, in western New York and western Pennsylvania.

—

Frank Dawson, who has been identified with the truck industry for the past 14 years, has resigned as designing engineer and production manager of the Master Truck Co., Chicago, to become general manager in charge of production for the Gary Motor Truck Co., Gary, Ind.

—

Herman A. Holz, metallurgical engineer and manufacturer of metallurgical and magnetic testing apparatus, has moved his office from 1 Madison Avenue to 17 Madison Avenue, New York City, where he is occupying the third floor.

Men of the Industry

Changes in Personnel and Position

British Trade Expert Will Try to Recapture Colonial Trade

LONDON, ENGLAND, March 17—The Association of British Motor & Allied Manufacturers, Ltd., has appointed Major R. E. Goddard as its overseas commissioner. He will make a tour of investigation of the markets of Australasia, India and the East and will include Ceylon, the Dutch East Indies, Australia, New Zealand, Japan, China, Malaya, Burma and India, in the order named. The whole tour will occupy about a year. It is possible that operations will be extended to other territories if this first year's tour is as satisfactory as anticipated. In this matter the association is acting in conjunction with the Overseas Trade Department of the British government. The government is assisting in every way, partly as regards finance and partly as regards official introductions and shipping arrangements.

Though Major Goddard has good credentials for his task, it is not clear how he is to compass so wide and distant a field of trade territory in a year. This is especially true because he is faced with the task of trying to dislodge American hold of the Australian and New Zealand markets, which were lost through lack of competent control and progressive ideals.

—

Ben Drewes, general superintendent of the foundry department of the Avery Co.'s motor works at Milwaukee, resigned April 1 to accept the position of foundry superintendent of the Kissel Motor Car Co., Hartford, Wis. He is succeeded by G. H. Joner, who has been assistant superintendent. Mr. Drewes went to the Avery motor works from the Kissel company about a year ago.

—

F. H. Berger, Detroit, former chief engineer of the Oakland Motor Car Co. and of the Abbott Co., is reported to be designing a new car. He has opened an office in the Hodges building.

—

C. R. Bulley has been appointed sales metallurgist to the Hess Steel Corp., Baltimore. During the war he was in charge of the design, building and operation of the heat-treating department of the Symington-Anderson Co., Ordnance, Rochester, manufacturers of 75 mm. field shells for the government. Prior to this he had several years' experience in the metallurgical department of the Halcomb, Midvale and Carpenter steel companies.

—

Edward S. Babcox has been appointed sales manager of the Rubber Products Co., Barberton, O.

Ford Mechanical Engineer Rumored Out

DETROIT, March 31—It is rumored here to-day that Charles Mongana, Jr., chief mechanical engineer of the Ford Motor Co., has resigned and is out. This cannot be confirmed at the Ford plant. It is also repeatedly heard on all sides that F. L. Klinginsmith, vice-president of the company, will retire immediately upon his return from his vacation.

—

Jack Neely, formerly with the sales department of the Roamer distributing agency at Kansas City, has been made assistant sales manager of the Barley Motor Car Co., Kalamazoo, makers of Roamer cars.

—

Edward T. Walling, associated with the Spranger Wire Wheel Co. for five years as assistant general manager, has resigned.

—

C. L. Thurston, export manager, has been placed in charge of the export offices of the Briscoe Motor Corp., Jackson, Mich., which have been opened at 1834 Broadway, New York City.

—

H. B. Niblette has been appointed supervisor of the tire sales division of the Thermoid Rubber Co., Trenton.

—

Allan S. Place, formerly with the Chevrolet Motor Co., Flint, has become superintendent of the Duplex Truck Co., Lansing.

—

W. D. Langdon, purchaser of metals for the Willys-Overland Co., Toledo, has been made assistant general purchasing agent of the company.

—

H. A. Reed, vice-president of Reed, Tilley & Co., Inc., exporters of automotive apparatus, has just returned from a business trip through Cuba.

—

Robert Evans, formerly service manager of the Page-Detroit Motor Car Co., is the new service director of the Landman-Griffith Co., Toledo.

—

John Gilson, Sr., Port Washington, Wis., founder of the Gilson Mfg. Co., manufacturer of gasoline engines, garden tractors, etc., died March 24 at the age of 69 years.

—

John Millen, of 366 Wood Avenue, Westmount, president of John Millen & Son, Ltd., 323 St. James Street, Montreal, Canada, died on Tuesday, March 25, in his 76th year.

—

Warner Gear Secretary-Treasurer Dies

CHICAGO, March 31—John Edgar Johnson, age 45, secretary-treasurer of the Warner Gear Co., Muncie, Ind., died suddenly Sunday morning after one week's illness. Johnson was born in Ashtabula, O., but was a resident of Muncie since the age of seven. He was also associated with the Morrison-Johnson Insurance Co. and a director of the Muncie Savings & Loan Co.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Additional Buildings for Stephens

FREEPORT, ILL., March 31—Approximately $125,000 is being expended by the Stephens Motor Car Co. on additional buildings, new machinery and equipment. Both of the main units are now in operation. Until March 1 only the Chicago Street plant, employing 227 men, was active, the old Freeport carriage plant, known as Plant No. 2, having been idle since the opening of the war, when lack of materials forced a temporary suspension. The latter unit will employ 300 men. The schedule calls for an output this year of 5000 cars. The No. 1 plant has been specializing in bodies for commercial trucks, and its business for 1918 aggregated $1,000,000.

Continental Motors Handled by Beckley Ralston

CHICAGO, March 29—Retail sales of single engines and spare parts for Continental motors for replacement in cars and trucks will be handled in this territory by the Beckley Ralston Co., accessory dealers and jobbers. The company expects to establish several repair depots in the city.

Duplex Truck Co.'s Production Increased 25 Per cent

LANSING, March 29—The Duplex Truck Co. has increased its production 25 per cent in the last three months, having completed its return from war to peace work without difficulty. The company now has 70 active distributing agencies throughout the country.

Olympian Increases 100 Per Cent in Production

PONTIAC, MICH., March 31—The Olympian Motor Car Co. has increased production 100 per cent in the last 30 days. The company is now running 10 and 12 cars daily. The last of the depth-bombs, which it was making for the navy, was completed Saturday.

American Bosch Co. Holds Sales Convention

NEW YORK, March 31—The American Bosch Magneto Co. closed its first sales convention last Thursday. The morning of the first day was taken up with an automobile trip around Springfield. Inspection of the works was held in the afternoon and business sessions in the evening. Wednesday and Thursday were given over to a discussion of trade matters and a review of new products. On Wednesday evening 100 executives and department heads sat down to a banquet at the Nayassett Club.

Giant Trucks in New Hands

CLEVELAND, March 31—The motor truck division of the Chicago Pneumatic Tool Co., making Giant trucks, was purchased Saturday by C. A. Finnegan, of Buffalo, N. Y., owner of the Buffalo *Commercial*, and A. Webber, who is interested with Mr. Finnegan in various enterprises. The business will be carried on with all branches and employees as before. H. B. Young will be associated with the new company in an executive capacity and will be in Chicago.

Bohnet & Co. to Enter Body Field

LANSING, MICH., March 28—John Bohnet & Co. have increased their capitalization from $10,000 to $75,000 and will enter the commercial body field. The company will be in production within 60 days. The present factory building, which has 60,000 sq. ft. of floor space, will be altered to accommodate the new department. W. G. Suprenant, Philadelphia, has been placed in charge of the body work.

Walker-Weiss Now Flint Axle

FLINT, MICH., March 31—The Flint Motor Axle Co. is the new name taken by the Walker-Weiss Axle Co. The capital stock and the policy of the company will remain unchanged, and with the exception of W. T. Walker, the same men are in control of its affairs. Mr. Walker disposed of his interest last April, and the remaining members of the concern took over his stock. The company has been making axles for the Chevrolet Motor Co. of New York, the Dort Motor Car Co. of this city, as well as for other outside concerns.

New Ford a Couple of Years Off

DETROIT, March 26—In a letter signed by Edsel B. Ford, sent to all dealers throughout the country, the Ford Motor Co. says that rumors about the new Ford are greatly exaggerated.

"In the first place," the letter states, "a large majority of the rumors afloat are distorted. A new car may be manufactured, but when we are not in a position to say, except that we know a new car could not possibly be designed, tested out, manufactured and marketed in quantity under two or three years."

Superb to Manufacture Trailers

MONTICELLO, IND., March 31—In addition to manufacturing parts and accessories the Superb Mfg. Co. will bring out a line of light and heavy trailers within the next 60 days. In order to have sufficient production facilities it is adding 20,000 sq. ft. of floor space to its present plant.

Traffic Truck in New Quarters

ST. LOUIS, March 31—The Traffic Motor Truck Corp. is moving from its original factory at 3810 Laclede Avenue to 8000 North Broadway, where it will have more than 100,000 ft. of factory space.

No Plans for Future of Inter-State

DETROIT, March 26—The General Motors Corp. has not stated to what use it will put the plant of the Inter-State Automobile Co., Muncie, Ind., purchased last week. The sale included the plant and 40 acres of ground adjoining, on which additions will be built. The Inter-State stopped the building of passenger cars after America entered the war, and concentrated its energies on production of trucks for the army. This contract has just been completed.

Wallace Barnes Opens Branches

BRISTOL, CONN., April 1—The Wallace Barnes Co. has opened branch sales offices in New York City at 50 East Forty-second Street with Lisle K. Lasher in charge, and another in Detroit, 618 Book Building, with Brown Joyce in charge.

New Cars Not to Be Driven from Factory

DETROIT, March 27—Detroit automobile manufacturers are discouraging their distributers who come to the city with the intention of driving away their cars. The manufacturers declare an automobile leaving the factory new is not a new car when it reaches its destination of 500 to 1000 miles away.

Lancaster Steel Products Bought by General Motors

LANCASTER, PA., March 29—The Lancaster Steel Products Co. has been sold to the General Motors Co. and will be operated as a subsidiary, it is announced. H. B. Cochran of this city will remain at the head of the local concern.

Clinton Planning New Truck

DETROIT, March 28—The Clinton Motor Truck Co. is bringing out a new 1-ton truck. The new model was already on the market before the war, but owing to war work and scarcity of material manufacture was suspended. The Clinton Truck Co. will locate its main plant in Cleveland.

Parsons Mfg. Co. to Move

DETROIT, March 28—The Parsons Mfg. Co., now on Stanley Avenue, will shortly be located at Bellevue Street, where enlarged facilities will be available. The company will occupy 30,000 sq. ft. of floor space in its new quarters, and expects to be in full operation by April 15. The Parsons company makes concealed hinges for passenger car bodies, also coach locks for sedans, limousines and other closed cars.

Daylight Saving Conserves Coal

WASHINGTON, March 29—The United States Fuel Administration stated to-day that 1,250,000 tons of coal were saved during the 7 months last year when the daylight saving law was in effect.

Peerless Shows Smaller Profit This Year

CLEVELAND, March 29—Net profits of the Peerless Truck & Motor Corp. and subsidiary companies for 1918 were $773,895, after all charges, interest, depreciation and $71,596 reserved for Federal taxes were taken off. Although depreciation, costs, interest and taxes were less in 1918 than 1917, net profits were $175,608 less and net sales $7,039,373 less for 1918 nad 1917.

The consolidated income account of the Peerless Motors Corporation and subsidiary companies for the year ended Dec. 31, 1918, compares as follows:

	1918	1917
Net sales	$11,890,079	$18,924,452
Cost of sales, plant	10,831,089	17,329,985
Depreciation of plant	214,808	291,849
Net inc. from sales	$844 182	$1,302,618
Other income	230,808	405,013
Total income	$1,074,990	$1,707,631
Deduct int. on notes	229,113	300,000
Interest on bonds	......	......
Premium on bonds	......	......
Organization expenses	......	......
Depreciation in investments	386	34,963
Fed. and income taxes	71,596	306,799
Balance	$773,895	$1,065,870
Net loss on munitions	......	......
Reserve for contingencies	......	116,367
Net profits for year	$773,895	$949,503

The consolidated balance sheet of the Peerless Motors Corporation, as of Dec. 31, 1918, compares as follows:

Assets

	1918	1917
Plant, land, etc	$2,957,027	$3,886,314
Patents, etc	2,862,035	3,710,520
Cash	1,790,890	2,869,569
Liberty bonds	1,600,731	......
Marketable securities	163,144	192,980
Inventories	2,465,448	5,318,743
Government claims	945,353	......
General vehicle investments	50,429	63,413

Contingent reserves	249,425	719,916
Surplus	4,588,972	4,371 918
Total	$14,592,147	$18,323,909

Despite the fact that net sales of the Peerless Truck & Motor Corp. show a decrease the corporation is in good financial condition. As of Dec. 31, 1918, current assets were $8,711,452 and current liabilities $1,380,039, making net working capital $7,331,413. Deducting from this the $3,453,800 bonds now outstanding there remains $3,877,613.

The signing of the armistice found Peerless with orders on hand covering substantially all of its truck material in process. These orders are about completed.

Crow-Elkhart Back on Its Feet

ELKHART, IND., March 31—The financial difficulties of the Crow-Elkhart Motor Co., brought on by war conditions, have been taken care of, and the company will soon resume normal production. Settlement of litigation following a petition for a receiver will enable the company to increase its output. H. T. Shafer & Co., Chicago, will have an interest in the concern from the fact that it will underwrite a bond issue of $600,000.

Both the Indiana company and Arizona corporation, forming the Crow-Elkhart Motor Co., will be dissolved, and the business will be conducted by the Crow-Elkhart Motor Corp., with an authorized capitalization of $10,000,000. H. T. Ligtig, as a representative of H. T. Shafer & Co., will be auditor and treasurer. It is announced that the former stockholders will receive an equal amount of stock in the new corporation, while the creditors who had accepted a settlement on a 25 per cent basis will receive also an amount equal to 75 per cent in the stock of the new corporation. The company now has orders for all the cars that can be produced within the next six months.

$801,607 Net Earnings of Hale & Kilburn

PHILADELPHIA, March 29—During the past year Hale & Kilburn Corp. has increased its net sales $240,970 over 1917, and its net earnings $216,212. Its balance sheet as of Dec. 31 last shows cash amounting to $164,216; a surplus of $498,404, and its total assets and liabilities, $7,517,637. Net sales to the amount of $4,476,552 and net earnings amounting to $801,607 are reported in the financial statement of the company, which follows:

	1918.	1917.
Total net sales	$4,476,552	$4,235,582
Net earnings	784,024	542,328
Miscellaneous revenue	17,583	43,067
Total net earnings	$801,607	$585,395
Interest charges, taxes, etc.	403,764	323,238
Surplus	$397,843	$262,157

Dividends Declared

General Motors Corp., Pontiac; regular quarterly dividend, 3 per cent on common, 1½ per cent on preferred and debenture stocks; all payable May 1 to stockholders of record April 15.

Standard Parts Co., Cleveland, 1¾ per cent, quarterly, preferred, payable April 1 to stockholders of record March 20.

Maibohm Surplus Amounts to $32,811

RACINE, March 29—A regular annual dividend of 6 per cent was declared at the annual meeting of the directors of the Maibohm Motors Co. The financial statement of the company for 1918 shows a surplus of $47,370, of which $14,559 was deducted to pay for the loss due to the fire on Dec. 3, leaving a net surplus of $32,811. Operations were continued in spite of the damage done to the plant. The company was not engaged on any war contracts, but, although working only on its regular products, production was somewhat curtailed because of government restrictions.

The following officers were elected for the new year: President, H. C. Maibohm; vice-president, T. W. Cushing; secretary and treasurer, I. O. Bormann; works manager, W. C. Maibohm, and director, Albert Mohr.

The balance sheet for the year ended Dec. 31, 1918, shows:

Assets

Cash and cash items		$157,272
Inventories		50,960
Deferred to operation		205,123
Machinery and equipment		94,477
Trademarks and good will		50,000

American Veneer Co. Soon Ready for Production

HAYWARD, WIS., March 31—A concern manufacturing veneers, veneer panels and other select hardwood products is being established here by the American Veneer Co., incorporated last year with a capital stock of $150,000. Work will start at once on a factory, 180 x 250 ft., to be ready about June 15, and to employ from 100 to 150 men.

Marwin Truck Co. Buys Leased Plant

KENOSHA, WIS., March 31—The Marwin Motor Truck Co. has acquired the former plant of the Skidd Mfg. Co., which it has been occupying since last fall under lease, and plans to erect several additions. The purchase price was $22,500, and more than an equal amount will be invested in new buildings and equipment during the year. The present output of the company is two machines a day.

Arrow-Grip Enlarges

GLENS FALLS, N. Y., March 31—The Arrow-Grip Mfg. Co. has increased its capital stock from $100,000 to $500,000, and will commence the erection of a new factory building soon. It has also opened an export office at 16 West Sixty-first Street, New York City, and continues to operate its warehouse in Chicago.

War Department Will Sell Surplus Trucks and Cars

WASHINGTON, April 1—A possible surplus of Army trucks and passenger cars is now considered likely, and in event that there are more vehicles than can be used by the Army these will be disposed of by the Director of Sales according to a plan which is designed to protect both the War Department and the automobile industry.

After the inventories, which are now being taken by the War Department, are completed, if it is found that there is a surplus of motor vehicles, the different branches of the Government will first be consulted to learn whether the surplus can be used to fill their requirements.

Various manufacturers of automobiles and trucks will be next approached to ascertain whether they will take over the vehicles of their own make to market them with their own machines to secure a fair market price for the Government and at the same time prevent disturbances of market conditions.

The net surplus remaining after the various branches of the Government and the manufacturers have been consulted will be disposed of to the public either through auction or by sealed bids. Full publicity will be given this sale throughout the country in order that the Government may realize the best results. In the meantime the public should understand that no motor trucks or passenger cars are being sold. It is anticipated that between the various Government departments and the manufacturers, whatever surplus is available will be taken up by them.

Standard Grading of Singapore Rubber

WASHINGTON, March 26—The Rubber Association of the Singapore Chamber of Commerce will establish a standard for Singapore rubber. A Standard Qualities Committee examines all samples of rubber offered for sale by members of the association and grades them.

Two standard qualities are recognized: Latex crêpe, which must be well prepared dry rubber of even color and free from all stains, spots and traces of oxidation; and F. A. Q. ribbed smoked sheet, which must be clean, tough rubber, free from mold, dampness or under or oversmoked sheets. The rules provide that all rubber sold as standard quality must be certified as such by the committee. The awards of the committee remain in force for one month from date of examination of sample. It is believed that this step will prove an important one and will result in "Singapore Standard" becoming of high rank in the markets of the world.

Pratt & Whitney to Make Hoke Gages

HARTFORD, CONN., April 2—The Pratt & Whitney Co. has secured the manufacturing rights for Hoke Precision Gages, which are now being made at the Bureau of Standards in Washington, as inspection and reference sets for Army and Navy use. The first sets ready for the market will consist of five blocks of 1-in., .5-in., .3-in., .2-in., .1-in., giving any tenth up to 2 in. The addition of ⅛-in., ¼-in. and ⅜-in. sizes will provide any eighth or tenth up to 2¼ in. in a set of eight blocks; and the addition of 1/16-in. and .05-in. blocks, making ten in all, will give any sixteenth or any .05-in. interval.

South May Have Tractor Plant

BIRMINGHAM, March 28—This city is being discussed as a likely location for the manufacture of the Mobile tractor, produced by the Mobile Tractor Co., which has its headquarters in Mobile. Officials of the company are desirous of putting up their own plant and plan to manufacture other automotive products along with the tractor. The northern and western demands are supplied through the Fort Wayne, Ind., plant, where the machine goes under the name Automotive tractor.

Freight Cars Released for Automobiles

NEW YORK, April 2—Regional railroad directors in the West and South have issued imperative orders that freight cars for the transportation of automobiles and which have been used for general purposes during the war must now be returned as speedily as possible into automobile manufacturing territory. In consequence 539 empty automobile cars passed east through Kansas City within a period of 48 hours last week. An official will be stationed in Detroit to have full control of the distribution of automobile cars in the Michigan-Toledo zone.

Elcock Returns to Atlanta Office of Cement Assn.

ATLANTA, April 2—Walter B. Elcock has returned as district engineer in charge of the Atlanta office of the Portland Cement Association, which position he left in March, 1917, to serve as Major of Infantry and Adjutant of the 157th Depot Brigade at Camp Gordon.

Government to Give Credit Ratings on Foreign Firms

NEW YORK, April 2—The Government is arranging to give American manufacturers credit ratings on foreign firms. Certain records and information obtained by the Bureau of War Trade Intelligence will be used as the nucleus to build up the service, which eventually will become a distinct bureau of the Government. For the present, the Washington office of the American Manufacturers' Export Association is prepared to answer inquiries regarding the financial responsibility of foreign firms.

Porter New Chief Engineer for Curtiss

NEW YORK, April 1—F. R. Porter has been appointed chief motor engineer of the Curtiss Engineering Corp., Garden City, L. I., where the experimental work of the Curtiss company is carried on. He has also been appointed chief engineer of the Curtiss Aeroplane & Motor Corp., Buffalo. His headquarters will be at Garden City. For the past year Mr. Porter was chief engineer at McCook Field for the Government, and in that capacity had to handle all new inventions in connection with engines and accessories.

Toby American Commerce Chamber Secretary

NEW YORK, April 2—George P. Toby has been appointed executive secretary of the American Chamber of Commerce in London. He will sail from New York about May 12.

To Build Texas Helium Plant

WASHINGTON, April 1—A helium plant is being constructed by the Government at North Fort Worth, Tex., to provide helium gas for airships. The plant will cost $900,000. Helium is a gas recently found to be particularly adapted to the filling of balloons. It is said to have 92 per cent of the lifting power of hydrogen and is not inflammable. The products of certain natural gas wells in Clay County, Tex., have been found best suited for the extraction of helium, and pipe lines will be arranged to Fort Worth.

Duplex Governor Chicago Office Moves

CHICAGO, April 2—The office of the Duplex Engine Governor Co. has been moved from 220 S. State Street to 28 East Jackson Boulevard.

Soss in Charge of Detroit Branch

BROOKLYN, N. Y., April 2—Samuel Soss has been placed in charge of the Detroit branch of the Soss Mfg. Co.

Decrease in February Oil Exports

WASHINGTON, April 2—The following is the complete tabulation showing the detailed decrease in oil exports, described briefly in the last issue of AUTOMOTIVE INDUSTRIES, for February and eight months previous:

	February, 1919		February, 1918		Eight Months Ended February, 1919		Eight Months Ended February, 1918	
	Gal.	Value	Gal.	Value	Gal.	Value	Gal.	Value
Mineral oils	165,689,425	$25,448.791	221.579.890	$24.031 982	1,755.072.757	$236,411,462	1,774,312,127	$183 933.493
Crude mineral oil	7,707,112	415,911	19.734.996	1,005.760	124.806.406	7.848,846	119,053.749	5,568,194

Calendar

ENGINEERING SHOWS

March 29-April 5 — Passenger Cars. April 8-12—Trucks, Brooklyn. Brooklyn Motor Vehicle Dealers' Assn. I C. Kirkman, Manager.

March 31-April 5—Cumberland, Md., Automobile Dealers Assn., Armory.

March 31-Apr. 5—New Orleans, La. Henry B. Marks, Manager.

April 1-5—Denver, Col.—Denver Automobile Trades Assn. Stadium.

April 3 — Macon, Ga. Motor Truck Demonstration, Macon Automobile Chamber of Commerce.

April 5-12 — Bridgeton, N. J. Fourth Annual, Automobile Dealers' Assn.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

April 8-12—Deadwood, S. D. Seventh Annual Cars and Tractors, Deadwood Business Club.

April 16-19 — Waynesburg, Pa. Automobile Dealers' Assn. of Greene Co., Armory. Frank L. Hoover, Mgr.

May 10-17—Bristol, Va.-Tenn. Cars, Trucks, Tractors, Airplanes and Accessories. Bristol Chamber of Commerce. C. W. Roberts, Manager.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

*Oct. 15—Paris. Grand Palais, International Automobile Mfrs. Congress.

Nov. 7-15 — London — Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December—Brussels. International Automobile Mfrs. Congress.

January—New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

TRACTOR SHOWS

April 15—Walla Walla, Wash. Sectional Tractor Demonstrations.

May 5—Sacramento, Cal. Sectional Tractor Demonstrations, Demonstration Field.

June — Denver, Col. Sectional Tractor Demonstrations.

July—Wichita, Kan., Automotive Committee of National Implement Assn.

Aug.—Aberdeen, S. D. Sectional Tractor Demonstrations.

RACES

†May 17—Uniontown, Pa., probably 112½ miles.

†May 31—Indianapolis, Indianapolis Motor Speedway Assn., 500 miles.

*July 5—Cincinnati, O., Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 22-23—Elgin, Ill. Speedway.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Oct. 1—Cincinnati, O. Speedway race.

†Sanctioned.
*Tentative dates.

CONVENTIONS

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

May 1-June 1 — Atlantic City, N. J.—Pan-American Aeronautic Convention and Exhibition — Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

Foreign Trade Opportunities

WASHINGTON, March 31—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has received requests for automobiles or parts agencies from individuals and companies in foreign countries. These are listed below. For further information address the Bureau of Foreign and Domestic Commerce and specify the Foreign Trade opportunity number.

Algeria—Agricultural machinery, petroleum for lighting and motors; automobiles. Correspondence should be in French. No. 28844.

Australia—Motor car and motorcycle accessories, motor car body and top materials and trimmings. Quotations should be given f.o.b. New York. The goods ordered will be handled and paid for by a firm in New York City. No. 28852.

Italy—Automobiles of 12 to 15 and 15 to 20 hp. Correspondence may be in Italian or French. Payment will be made on receipt of goods through bank. No. 28854.

Italy—An agency for automobiles and motorcycles. Correspondence may be in English. No. 28834.

Italy—An agency for agricultural apparatus. Correspondence may be in English. No. 28789.

A British Indian company, with buying headquarters in New York City, wishes to purchase direct from manufacturers automobiles and accessories. Payment will be made against documents in New York. No. 28794.

France—An agency for southern France of automobiles and trucks. No. 28795.

Switzerland—Agencies for cheap and medium priced automobiles. Correspondence should be in French or Italian. No. 28816.

Italy—An agency for motorcycles. Correspondence should be in French or Italian. No. 28823.

Mead-Davis for Distribution, Sales and Advertising

CHICAGO, March 29—The Mead-Davis Co. has been formed with temporary offices at 814 Hearst Building. Its activities will include factory products distribution, sales and advertising. F. L. Mead will be in charge of the sales department and B. E. Davis, head of the advertising department. Mr. Mead resigned his position as general sales manager of the Dearborn Truck Co., where he has been for three years, on Feb. 1. He has also been connected with the General Motors Truck Co., Buick Automobile Co. and Oakland Motors Co. Mr. Davis has been advertising manager for the Dearborn Truck Co. for the past two years. The new company plans to act as director of advertising and sales for manufacturers.

Parts Coming From Louisville

LOUISVILLE, March 31—Announcement was made here to-day by the Louisville Industrial Foundation that the Louisville Pattern Works, specializing in patterns for automobile parts, will begin operations within 30 days. The concern has been incorporated for $15,000, the incorporators being John F. Reeder, A. J. Roth and P. W. Roth of Muncie, Ind., where they have been engaged in pattern and foundry work for motor cars. Only skilled labor will be employed. Machinery and equipment have been ordered and will be installed as soon as the plant's location is selected. The concern is considering several sites. It will make patterns for engines, cylinders, crank cases, transmission cases and other automobile parts.

General Motors to Build 1000 Homes

FLINT, MICH., March 28—Work is about to start on construction of 1000 homes for Buick and Chevrolet employees, which will be completed by Dec. 1. The General Motors takes this action to relieve the house shortage here, which is becoming acute. The new homes will be built on the outskirts of this city, in Flint township. The company proposes to construct sewers, water mains, pavements, sidewalks and to provide recreation centers. The homes will be sold on an easy payment plan.

Overland Mechanics O.K. Wage Scale

TOLEDO, O., March 31—Machinist employees of the Overland plant met Saturday and approved the Willys-Overland new wage scale agreement. The agreement will affect the Overland plants at Toledo, Elyria, O., and Elmira, N. Y. A sliding scale will be asked, with a minimum wage increase from 55 cents to 70 cents an hour for machinists, and other scales have been written for helpers and similar workers.

Onondaga Steel Adds to Directorate

SYRACUSE, N. Y., March 29—Morton D. Whitford, treasurer of the Semet-Solvay Co. and a director of the Syracuse Trust Co., and Charles H. Canfield, general auditor of the company, have been added to the directorate of the Onondaga Steel Co., Inc. The company is planning to move its offices and remaining furnace and melting equipment to its newly acquired site at Eastwood this spring. Plans have been made for the immediate construction of a temporary office building, and an addition to the main building, 40 x 40 ft., to house the blacksmith shop and the small hammer shop.

Tractor Service Book

We have received from the Gurney Ball Bearing Co., Jamestown, N. Y., a copy of a recently issued Tractor Service Book. It contains instructions for the care and operation of tractors, particularly in relation to bearings, lubrication, engine starting and magneto and other electrical equipment. There are also an article on the draft of tillage implements, an article on field operation and adjustment of light farm tractors, the tractor standards adopted by the S. A. E., miscellaneous data and a number of blank sheets on which data concerning plowing operations can be entered.

International Air Navigation Regulations

Paris Commission Adopts Preliminary Code — Will Be Basis for Final International Rules — Recognizes Rights of Individual Countries

By Allen Sinsheimer

WASHINGTON, April 7—The first comprehensive attempt to formulate an international code controlling aërial navigation has been completed by an inter-ministerial commission at Paris, appointed for this purpose. The first copy of these regulations has just been received in this country and is printed herewith.

Following a brief explanation of the past history of the attempts to formulate navigation regulations, the code comprises fourteen articles, with a number of annexes and programs.

Primarily, the code is intended to regulate navigation throughout the world, although for the time being and until the peace treaty is signed only the Allies and the United States are recognized.

Neutral countries will be allowed to join after peace terms are completed, and at that time the attitude toward Germany and other enemy countries will be decided. The right of each individual nation to formulate individual aërial regulations is recognized in so far as these regulations do not conflict with the international code.

The work of the commission was quite complete, and the general scheme includes provisions covering practically all of the more important problems of civil aviation. In order to secure permission to fly over the territory of any other country, an aviator must be registered in one of the nations recognized by the code, must possess a flying license, and the pilot of the machine must be a citizen of one of the recognized countries.

The airship must be provided with a route-book, corresponding to a ship's log, in which the nature of the airship, register number, name, nationality and residence of the owner and pilot, crew, passengers, complete details of the trips, memorandum of transported merchandise and route incidents must be recorded.

Any of the recognized countries may forbid private individuals to fly over certain zones of its territory. The carrying of cameras, war appliances or any dangerous explosives is forbidden except when specially authorized.

Military planes are not allowed to fly over foreign territory.

All the recognized countries are to agree to provide assistance to any airship when it is needed, and especially to build landing fields. Tariff, hygiene and landing-field regulations are to be determined by the individual countries.

Technical conferences are to be held at which representatives of at least two-thirds of the recognized countries will be present and at which additional provisions and modifications of these provi-

sions will be suggested for the final draft of the international code, which will be valid in every contracting country and which cannot be renounced until 3 years after notice is given.

The airships of each country will be lettered to denote their nationality and type of ship, and these letters must be displayed prominently.

Licenses will be granted after sufficient trials before competent aeronautics associations or in the presence of public authorities. In this particular provision there is opportunity for misuse of the regulations, inasmuch as it can become possible for an aeronautic association, by this authority, completely to control aeronautics in its particular country.

Furthermore, the navigation license must include complete and intimate data relative to each airship, and any rules which will allow a private aeronautics association to possess such information in its files also allows for further abuse.

Certificates of competency are to be provided each pilot and engineer of an airship by the country to which he belongs.

Detailed regulations regarding the use and placing of lights, driving, signals and use of ballast are given.

Motor-driven airships must give right of way to all other ships, including free balloons and dirigibles, according to the regulations, which apparently means that airplanes must allow right of way to balloons and dirigibles. A distance of 200 meters must be maintained between airships whenever possible; when they are closer than this, special regulations are provided for their operation.

Pilots' tests include flights for 1 hour at an altitude of at least 2000 meters, descent in a volplane with the engine shut off, flying around posts, landing with the engine completely stopped when the airplane touches the ground or water, endurance tests and written or verbal technical examinations. Pilots must have theoretical knowledge regarding air resistance, the functions of the various mechanisms, fitting up of planes, aërial navigation rules, complete engine construction, and must be versed in climatic conditions and map-reading.

Following is the report, including the code of the Inter-Ministerial Commission of Civil Aeronautics at Paris:

Regulations for Air Navigation

Inter-Ministerial Commission of Civil Aeronautics

THE end of the war is opening new vistas to civil aeronautics. A large number of machines and pilots given back to pacific activity are ready to develop air locomotion in all its forms, in Belgium, France, Great Britain, Italy and the United States. Aeroplanes or even dirigibles will certainly be precious help for touring, trade, public services, etc.

Great Britain, fearing to lose her privileges as an island, did not seem at first to welcome the invention, but she has become now much interested in the development of air navigation. France, which was the seat of the first international conference, which in 1910 attempted to solve the difficult judicial problem, must on her behalf and that of other nations resume the work which she so successfully started 8 years ago. Such a task has been assigned to her by decision of the Inter-Allied Parliament held in London last November. In 1910 Great Britain's hesitation had caused the conference to be postponed with no other result than an unsigned project of international convention; but to-day Great Britain's opposition has ceased. The 1910 text, too carefully detailed, can be given a shorter form. Moreover, at that time lack of experience prevented certain regulations from being settled; but to-day the necessary modifications can be made.

In 1910 four powers which are now the enemies of France were present at the conference, along with Denmark, Netherlands, Sweden, Switzerland. There is no question of treating the first four like the five others and the neutrals like Belgium, Great Britain, Italy, Portugal, Roumania and Serbia; the reciprocal freedom of navigation can only be granted with full confidence to the States which alone, from war to victory, have drawn their bonds closer. The European allied nations represented at the 1910 conference, and the United States of America alone, will be invited to exchange their views from which, on the morrow of victory, the first great conventional law of the air will spring. Later on neutrals can join. Then peace negotiations will decide in what degree it may be extended to the various enemies.

It is, therefore, in this spirit that the Inter-Ministerial Commission of Civil Aeronautics, which had not waited for the armistice to anticipate and examine the question, drew up the following project of convention, to be taken as a basis for an exchange of views, in Paris, between the European Allies and American associates.

Project of International Convention Regarding Air Navigation (1)

Article I

Airships owned by citizens of one of the contracting States alone, answering the following conditions, are authorized to fly over the territories of the contracting States:

It is necessary:

1—To be duly registered in one of the contracting States, according to Regulation, Annex A.

2—To possess a flying license, according to Regulation, Annex B.

3—To be driven by nationals of one of the contracting States and be provided with technical certificates and licenses, according to prescriptions of Regulations, Annex C.

The original, or an authentic copy, of each of these documents must always be kept on board and presented at any requisition.

Article II

The airship must have a routebook along with a list of the transported persons, goods and objects, drawn up according to the prescriptions of Regulations, Annex D.

Article III

Each State is allowed to forbid private individuals, no matter what their nationality, and under the penalties referred to in its regulations, to fly over certain zones of its territory; previous notice is given to the other contracting parties.

Article IV

It is forbidden to carry, without special authorization, camera, war appliances or ammunitions, as well as any other dangerous explosives.

(1) The project was unanimously adopted in the meeting of Nov. 13, 1918.

Article V

Except if especially authorized, the military airships of a contracting State are not allowed to fly over the territory of the other contracting States.

Article VI

In case of war, the stipulations of the present convention do not affect the liberty of action of the contracting States, either as belligerents or as neutrals toward belligerents.

Article VII

The navigation must be effected according to the Regulaions, Annex E.

Article VIII

The contracting States undertake to assure all measures with a view of giving airships the necessary help when landing, especially in case of breakdown.

Article IX

The present Convention does not affect the special regulations of the contracting States as long as they stand outside its clauses.

Special agreements settle the conditions relative to customs, stations, hygiene, etc.

Article X

The present Convention applies to all colonies, possessions or protectorates.

Article XI

Third parties will be authorized to adhere to the present Convention on condition the contracting States unanimously grant their consent.

Article XII

The present Convention will be put into force at the same time as the exchange of ratifications, which will take place within 6 months at the latest.

These ratifications will be deposited at the archives of the French Foreign Office.

Article XIII

Technical conferences which will be held at the request of at least the two-thirds of the contracting States will proceed to the examination of the modifications to be made in the regulations added to the present Convention.

Article XIV

The present Convention cannot be denounced before the expiration of a 3-years' delay, dating from its signature.

The denunciation only concerns the State which notifies it and 1 year after.

Annex A

Conditions of Registering

The name, surname, nationality and residence of the owner and constructor will be entered in a register.

The registering, inscribed in Roman types, will include:

I—The capital letters (one or several) characteristic of the owner's nationality, indicated as follows: BELGIUM, *B;* UNITED STATES, *US;* FRANCE, *F;* GREAT BRITAIN, *GB;* ITALY, *I;* PORTUGAL, *P;* RUMANIA, *R;* SERBIA, *SB*.

II—The small letters, characteristic of the nature of the airship: a, for aeroplanes; b, for free balloons; d, for dirigibles.

III—The figures and letters of the record number of the airship in the register.

Everything according to the following model: *"USa101G"*

The letters and figures representing the registering indication of the airship must be at least 45 centimeters high. Their width must be two-thirds of their height and their thickness the sixth of their height. They must be printed in black on a white background and placed:

For *a dirigible or balloon:* On the top part of the balloon, under the car, and on both vertical sides of the car.

For *an aeroplane:* Above the upper wing, under the lower wing and on both sides of the helm or on each of the outer parts of the helms.

The States must send to one another the list of their registering through the medium of the French Government.

Annex B

Navigation License

The navigation license will only be granted after sufficient trials effected in the presence of a public authority or competent aeronautics association belonging to one of the contracting States.

This navigation license will include the following indications: Name or firm and residence of the constructor; place and year of manufacture; number or any other identity indication given to the machine by the constructor; characteristics of the airship.

The latter must be the following:

For free balloons:

1—Dimensions of the envelope (diameter, circumference, volume).
2—Diameter of the orifice of the appendage.
3—Nature of the envelope.
4—Disposition of the driving and inflating orifices.
5—Weight of the envelope, net and car.

For dirigibles:

1—Regarding the envelope: Its model and chief dimensions.
2—Regarding the car: Number, dimensions, places.
3—Regarding motors: Number, model, diameter of cylinders, length of pistons, normal power and consumption.
4—Regarding tanks: Number, specification, volume.
5—Regarding propellers: Nature, number, places, diameters.
6—Regarding helms of directions: Disposition, nature, number and places.
7—Regarding empennage: Disposition, number, places.
8—Necessary crew for the driving of the balloon.

For aeroplanes:

1—Model of the machine.
2—Sustenation surfaces, number, dimensions.
3—Motors.
4—Tanks.
5—Propellers.
6—Helms.
7—Empennage.
8—Landing disposition.
9—Fitting.
(3–9) Same as for dirigibles.
10—Necessary weight (fuel, accessories and crew being deducted); that is, available weight for passengers and goods.
11—Speed, horizontal at 1000 meters altitude.
12—Time of ascent (empty and with full load) at 1000, 2000, 3000 meters, etc.
13—Ceiling (empty, full load).
14—Necessary crew to drive the airship.

Any modification made in the machine must be declared to the competent administration. The visits made by public authorities, with a view to examining the navigation conditions of airships, must be mentioned in the certificate, along with repairs and modifications.

Annex C

Certificate of Competency

Each of the members, pilot, engineer, or any other specialist of the driving crew of an airship must be provided with a special certificate of competency according to the enclosed model, delivered after theoretical and practical examinations by the competent authorities of the State he belongs to.

This certificate bears the names, surnames, nationality, birth date and place, photograph and signature of the owner, who must be at least 18 years old.

The present program of the examinations is as follows:
(See *Regulation of the Aviator Pilot's Certificate.*)

Annex D

Routebook

The routebook, according to the enclosed model, must contain the following indications:

Nature of the airship, registering number, name, surname, nationality and residence of the owner.

Moreover, for each journey: Name, nationality and residence of the pilot, crew and passengers; the place, date, time of departure and route incidents (landing, accidents, etc.)

The list or memorandum of the transported goods must be added to the book if necessary.

Annex E

AIR TRAFFIC REGULATIONS

Regulation Regarding Lights

Article I—The regulations regarding lights must be observed, no matter the weather, from sunrise to sunset. In the meantime, an airship must not show any light liable to be mistaken for a regular light.

The use of flashlight is forbidden except for landing.

Article II—Motor airships must carry the following lights, the radius of visibility of which is determined in relation to the vertical plan P of longitudinal symmetry of the airship, when the latter is in a horizontally rectilinear position of flight:

a—In the forepart, a white light placed in the plan P, visible in a dihedral with vertical faces, each forming a 110-deg. angle with P, according to the following:

b—In the back part, a white light placed in the plan P, visible in a dihedral with vertical faces, each forming a 70-deg. angle with P, according to the sketch.

c—On the right, a green light visible in a dihedral with vertical faces, respectively, forming 0-deg. and 110-deg. angles with P, according to the sketch.

d—On the left, a red light, visible in a dihedral symmetrical with the preceding one.

e—The faces of these four dihedrals must be provided with vertical screens so that the light cannot be seen in the obscure field of the dihedral.

f—The white light in front must be visible at a distance of at least 4 kilometers, the white light behind and the green and red lights at a distance of at least 2 kilometers, in a dark night, with no mist.

g—The lights must not be screened in any part of the illuminated field. To this effect, each light must be duplicated so that the couple of lights yield the regular dihedral of visibility above and under the airship.

However, regarding dirigibles, the lights need not be visible in the upper sheet of the cone of revolution, the generatrixes of which are inclined by 60 on the vertical.

Article III—Free balloons must have a ready white light, of at least 2 kilometers range; this light must be pulled up at the approach of another airship.

Route and Drive Regulations

Article IV—Motor airships must always keep away from free balloons and dirigibles when the latter carry signals similar to those of free balloons.

Article V—A motor airship must always keep away from any other airship at a distance of at least 200 meters, and drive according to regulations referred to in Articles VI and VII, as soon as it is aware that the distance is getter shorter.

When airships are less than 200 meters in depth away from one another, they must drive as if they were at the same altitude, according to the following regulations:

Article VI—a—In the case of two airships going in the same direction, the one which is behind, when the quickest, must drive so as to keep away from the other. It must not get beyond the other by diving but by flying over, on condition that it can keep away at a distance of at least 200 kilometers.

If it wants to get beyond without flying over, it must pass by on the left.

b—When two airships are going crossing directions, the one which sees the other on its right must drive so as to keep away, avoiding to cross in front of the other. As to the latter, if it thinks necessary to move, it must do so, so as to increase the space between both airships.

c—When two airships are going in opposite directions, they must both keep to the left.

Article VII—The airship which is going a free way and wants to turn around on the left must not do so unless it is sure that it is not followed by another airship at a distance less than 200 meters. In case it cannot get sure of it, it must turn on the left within at least a 500-meter radius.

Article VIII—When a dirigible voluntarily stops, it must pull down, five meters under the car, a black ball, of a diameter at least one meter. In that case it remains submitted to the same regulations as moving airships.

If it cannot control its movements, it must show another black ball, two meters lower than the first one, and is then like a free balloon.

In both cases, at night, it lights its white lights only, and is similar to free balloons.

Article IX—Airships must use, under the circumstances mentioned further on, phonic signals emitting three kinds of calls, according to schemes A, B, C.

Scheme A—Short sounds of 3 sec. at intervals of 3 sec. These calls must be heard in all kinds of weather: fog, mist, snow or heavy rains.

Scheme B—Alternatively short sounds of 3 sec. and long sounds of 9 sec. at intervals of 3 sec. These calls must be emitted by airships on the point of landing.

Scheme C—Long sounds of 9 sec. at intervals of 3 sec. These calls must be emitted, if possible, by airships in distress.

Distress Signals

Article X—Besides phonic signals, according to Scheme C, dirigibles and free balloons must observe the following prescriptions, as much as possible, in case of distress above land as above sea:

a—In the day time, dirigibles must place a triangular red flag under the car, and show the two black balls referred to in Article VIII.

In the night time, they must show and wave a white light, and put out their side lights.

b—A free balloon must hoist a triangular red flag under the car in the day time and show a white light at night.

Use of Ballast

Article XI—It is forbidden to use other ballast than fine sand or water.

Regulation of the Aviator Pilot's Certificate (Public Transport)

Practical Tests

Tests of Height and Volplane—Fly without landing for one hour at least and keep up at an altitude of at least 2000 meters above the starting point.

The descent must end in a volplane, motor shut off. This volplane must begin 500 meters at least above the landing ground. The landing must be effected at a distance of 200 meters from a point fixed beforehand by the commissaries controlling the test, without restarting the motor.

Handling Test—Fly without landing around two posts (or buoys) situated at a 500-meter distance from one another, effecting an interrupted series of figures of eight, each loop of which must alternately include one of the two posts (or buoys). This flight must be effected at an altitude of 200 meters above the ground, without touching the soil or water, on a distance of at least 5 kilometers long, the distance counted for each figure of eight being that between the two posts (or buoys).

Landing must be effected according to the following indications:

1—Shut off the motor altogether at the latest when the aeroplane touches the ground or water.

2—Definitely stop the aeroplane at a 50-meter distance from a point designated by the candidate before the test.

Test of Endurance:

1—A triangular journey of 200 kilometers, the distance being counted according to the length of each side of the triangle, which must not be less than 20 kilometers. This journey must be effected on the same aeroplane within 24 hours, including two compulsory landings fixed by the commissaries. Landing must be effected on the grounds of departure at least one hour after sunset and one hour before sunrise.

2—A journey without stopping, of at least 50 kilometers, in a straight direction, effected with the same machine, and on the same day, between sunrise and sunset.

This test includes a distance of at least 100 kilometers at an altitude over 1500 meters.

After having completed the satisfactory practical tests,

the candidate must undergo, after convocation, two examinations, one on aeroplanes and driving, the other on motors, according to the program given herewith.

Observations

The delivery of the certificate is optional. The candidate will be on board in each practical test.

Practical tests must be effected within six months from the first to the last test.

They can take place in any order and be started again once each.

The departures, stoppages and landings will be verified by two competent controlling commissaries, who will send to the authorities the reports drawn up in the form required. These reports must indicate the various incidents, especially regarding landing.

The candidate must furnish, at the beginning of each test, unquestionable identity papers, which must be presented to the commissaries.

Registering barometers must be sealed by the commissaries, who will tell the candidate that he must carry out the test so that the line 0 of the diagram, before and after landing, be clear enough and especially sufficiently prolonged after the arrival, and that the diagram be absolutely legible. The commissaries will refuse graduated barometers above 1000 meters.

The diagram of each test must be taken off by one of the commissaries, who will make sure that the graduation of the sheet corresponds to the altitude indicated by the plate fixed on the barometer case. The diagram, signed by both commissaries, will be added to their report.

The pilots provided with the military certificate of aviator pilot will also be granted the pilot's certificate for public transports.

As to private people, the pilot's certificates delivered by the Aero Club, along with the military certificate, will amount to a driving license.

Program of the Knowledge Required by the Candidate for Aviator Pilot's Certificate

I—Aeroplanes

Summary theoretical knowledge regarding the resistance of air applied to aeroplanes, helms and propellers.

Function of the various organs and the handling thereof.

Fitting up of aeroplanes, propellers, landing gear, helms and handling thereof.

Air traffic regulations.

II—Motors

Generalities on sparking engines and rotation at four speeds.

Study of the various functions of the motor; distribution, carburetion, lighting, escape.

Characteristics of aviation motors.

Ideals on regulating, function of the steering-wheel, equilibrage.

Generalities on the constitution, construction, regulating and putting engine in a proper condition.

Causes of the bad working of motors.

Ideas on spirits and oils.

Detailed description of the aviation motor used.

Regulating, driving, greasing, upkeep, taking to pieces and putting together of the chief organs with the means on board.

Finding out the causes of breakdowns.

III

Practical knowledge of the special conditions of air journeys; care to be taken in cold weather, at high altitudes, rain, fog.

Reading of the map, direction, etc.

"The Consulting Engineer"

By R. A. C.

THE writer notes with pleasure the excellent editorial entitled "The Consulting Engineer," appearing in the March 6 issue of AUTOMOTIVE INDUSTRIES and wishes to express his appreciation and at the same time compliment the editor for the efficient and able manner in which the subject was handled and presented.

The writer could cite many instances of where great financial losses were caused through the unwillingness of not only the plant engineer but the business management as well, to call in a consulting engineer.

It seems to be the opinion of most manufacturers that consulting engineers are over-technical, fussy and impractical, and are only useful after something has gone wrong, thus interfering with the production, operation or sale of the commodity manufactured. The writer has attended the last rites of a number of concerns that put off calling in a consulting engineer until it became evident that what was needed was a referee in bankruptcy instead.

The most economical time to call in a consulting engineer is in the beginning, before the new design is made. If called in at that time, a good broad visioned, well informed consulting engineer becomes a dividend paying investment in that he not only instructs the plant engineer and the business management as to the best method of procedure but, most important, he advises them as to what not to do.

To be successful in the consulting engineering profession, it is necessary for an engineer to be very broad visioned and intensely practical, and he must have commercial ability so as to be able to quickly determine the commercial value of new ideas or suggestions offered and at the same time be able to point out the practical limitations of theory in design.

The more capable and efficient the plant engineer is, the more willing he is to have a consulting engineer called in, as he soon discovers that the value of his services to his employer are materially increased by the assistance given him by the consulting engineer and finally regards him as a real friend to whom he can go for assistance when difficult problems present themselves, without feeling that his own value has been lowered in the estimation of his employer.

Aircraft Yearbook

A YEARBOOK for the year 1919 has just been issued by the Manufacturers' Aircraft Association, Inc., New York City. It is virtually a record of what the members of this association accomplished during the past year. The book has been compiled by a committee of the Association, Fay L. Faurote acting as editor. According to the preface, the Annual is intended also to constitute, in some measure, a history of aviation, both industrial and scientific, and a repository of aeronautical information.

After an introductory chapter on the future of aviation, there follows a short article on the history of the Manufacturers' Association. Then follow articles on the different companies forming the membership of the association, giving their histories, their personnel and a description of the product they are turning out. It is stated that the facts for this record were obtained through the co-operation of the individual companies.

The remainder of the book contains a list of Government organizations having to do with aircraft development, a list of the world's aces, a history of the early period of aviation, and a chronology of important events in connection with heavier-than-air flying machines; also articles on "Aerial Mail To-day and To-morrow," "The Weather Bureau and Aviation," "Balloons," "Important Events in Balloon History," "Mapping of Aerial Routes," "Landing Fields" and "How Can Men Fly?", a list of air service stations, designation of aeroplanes, a list of books on aeronautics, and a list of aeronautical magazines.

Worm Gear Efficiency

Description of a Test Rigging for Determining the Efficiency of Worm and Wheel Rear Axle Drives—Some of the Results Obtained in the Tests

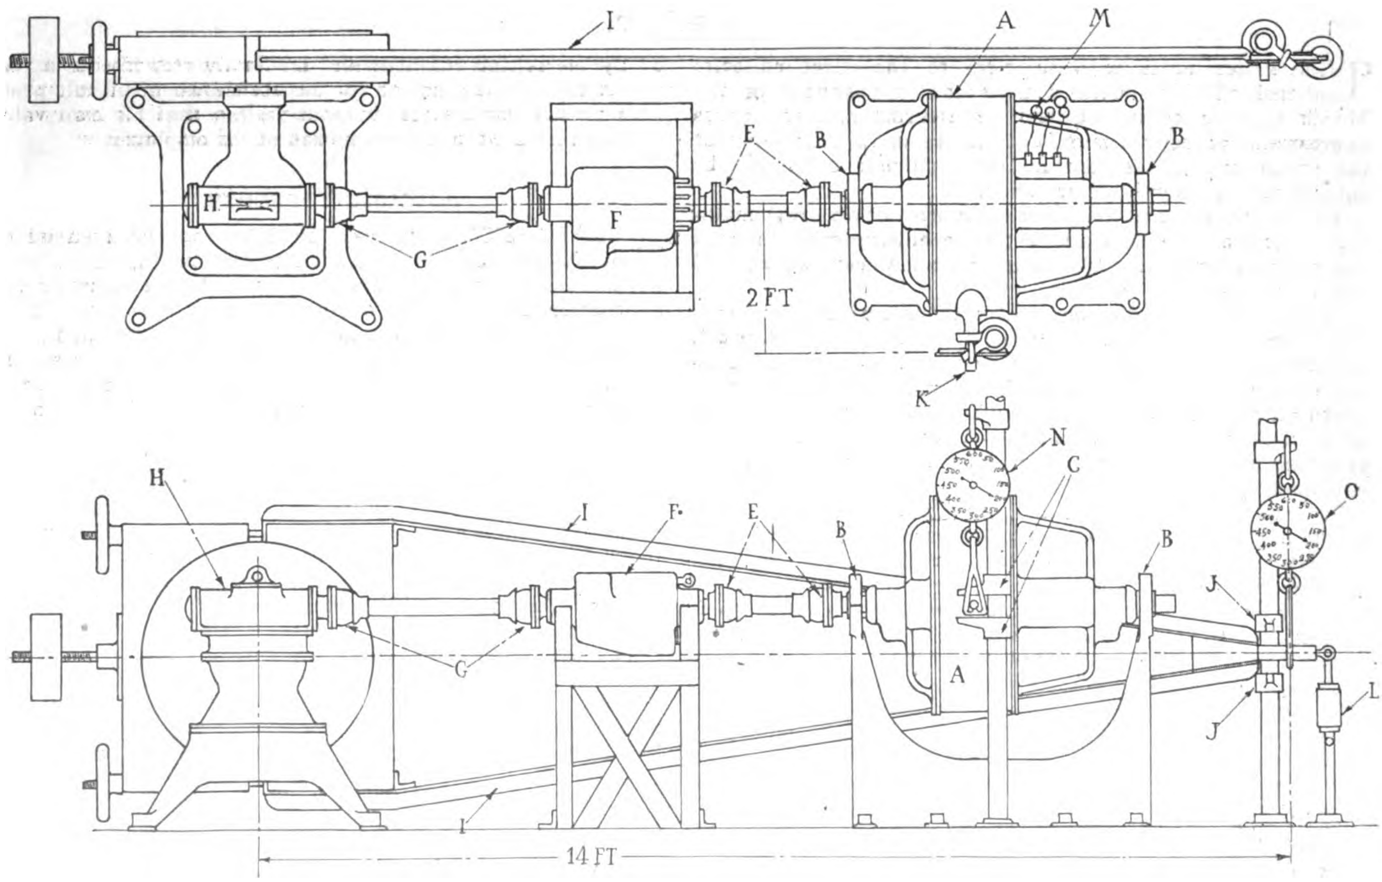
By C. H. Calkins

MUCH confusion exists regarding the actual mechanical efficiency of worm gears. The zealous gear salesman and the academic treatise tell us that their efficiency is 99 per cent, or better, and the shop man, who is not familiar with modern worm gears, denies that their efficiency is better than 60 per cent.

It should, in the beginning, be realized that more advance in the theory and practice of worm gear manufacture has been made in the past 8 or 10 years than perhaps in the previous 50 years. Until recently worm gears with leads of from 3 to 6 in., such as are now common on automobile rear axles, were rarely seen. Grinding the teeth of a worm was unheard of, and little was known of correct tooth shapes and angles or their relation to efficiency and reversibility. Still less was known of the relation of various steels and bronzes to efficiency and durability. Even at the present time few brass foundries are able to produce a gear bronze which is properly cast and chilled to enable it to meet the high requirements of the modern worm wheel. Every foundry thinks it is easy to do this, but the writer has found by bitter experience that only those foundries which have specialized on this work and which have had long experience are able to produce desirable results.

It was with a view to clearing up some of this uncertainty regarding worm gear efficiency and to demonstrate to themselves what a modern high-grade worm gear could do that the Baush Machine Tool Company, of Springfield, Mass., worm gear specialists, and a truck manufacturer jointly undertook to obtain some accurate, authentic efficiency data. The truck company was not only interested in obtaining worm gear data, but wanted to know the total power loss from engine to rear wheel; consequently tests were made covering the truck gear box or transmission losses, together with the rear axle worm gears. Worm gears alone were also tested.

The Baush Machine Tool Company had previously built a small efficiency machine suitable for testing gears up to 5 or 6 hp., so this experience was brought to bear on the design of a larger machine, which was finally completed in the summer of 1917, as shown below. The tests described below were made at the Baush Company's plant by representatives of the truck company and the Baush company, and were made solely with the



Plan and elevation of the Baush company's worm wheel testing stand

idea of obtaining information, and the results have never been used in an advertising way.

Referring to the drawing, A represents a 230-volt, 32-hp. motor with a speed variation of from 300 to 1200 r.p.m. The fields are mounted on ball bearings indicated at B. This leaves the fields free to oscillate a short distance limited by the stops C. The armature shaft is extended by means of two universal joints E to truck transmission F. This transmission and the universal joint are regular standard equipment as used on the truck company's 3-ton truck. The transmission has 4 speeds and is ball bearing throughout, the construction being of the very highest grade. The armature shaft is continued by means of two more universal joints G to a standard worm gear housing H. The worm wheel shaft, which in a truck would correspond to the rear axle drive shaft, is extended on one side only, and carries the drum of a prony brake. This shaft is mounted on ball bearings. The prony brake is of cast iron, 8 in. wide by 36 in. in diameter, and is hollow to admit the introduction of water for cooling purposes. It carries two heavy wooden brake shoes, which are adjustable by means of hand wheels. These brake shoes are extended into a 14-ft. lever I, the oscillation of which is controlled by stops J. Both the prony brake arm and the 2-ft. armature arm X are very accurately counterbalanced by means of adjustable weights, and the longer arm is held from vibration by a dash pot L, the piston of which is included in the balancing adjustment. The motor leads are extended by means of rigid terminals into mercury cups M, so that any error which might be due to the weight of the leads is obviated. The spring balances shown at N and O are the standard product of John Chattilon & Sons, and register up to 600 lb. The whole machine is rigidly mounted so as to reduce vibration to a minimum. The temperature of the oil bath, in which the worm gears ran, was taken by means of a calibrated thermometer which dips directly in the oil.

The results below are the average of a great number of tests, the idea in this paper being to set before the reader only net results. Before each test the brake and motor field balance were verified before witnesses, as in fact were all readings.

Several makes of worm gears were tested, but in this paper we will consider only those made by the Baush company. Also three bronze mixtures were tried, and it was found that mixtures had considerable influence on durability, and, consequently, efficiency. Whitmore's No. 45 oil was used in the transmission throughout all the tests and 600 W. Steam oil was used in the worm gear housing.

The ratio tested was 3:27, which gives a reduction of 9 to 1. The centers were 7.721 in. The normal angle of the worm tooth was 55 deg., the lead angle, 26 deg. 27 min. 8 sec. The circular pitch of the wheel was 1.468 in. The worm pitch diameter was 2.819 in. The worm was made of a low-carbon carbonizing steel, the analysis being approximately as follows:

Carbon	0.16 to 0.23
Manganese	1.00 to 1.2
Sulphur	0.045 to 0.06
Phosphorus	0.045 to 0.06

The worm teeth were carbonized, hardened, ground and polished.

The worm wheel was made of a bronze of the following mixture:

Copper	89 per cent
Tin	11 per cent

The casting was poured in a graphite mold so that the periphery to a distance of perhaps ½ in. was chilled. The Brinell test was 107 points.

Both worm and wheel were the regular product of the Baush company, selected at random from regular production.

Referring again to the drawing, it will be noted that the distance from the center of the armature to the end of the motor field arm is 2 ft., while the distance from the center of the prony brake to the end of the arm is 14 ft. In some of the tests the brake arm was 9 ft. in length, but in order to get the desired torque and still be within the capacity of the motor, it was necessary to lengthen it. The final results are not affected thereby.

The formulæ used were as follows:

$$\text{Efficiency} = \frac{\text{Brake pull} \times \text{length of brake arm } l \text{ (9 or 14 ft.)}}{\text{Motor pull} \times 2\text{ ft.} \times \text{total reduction}}$$

$$\text{Horsepower input} = \frac{\text{Torque on motor fields} \times 2\text{ ft. radius} \times \text{R.P.M. of motor}}{5252}$$

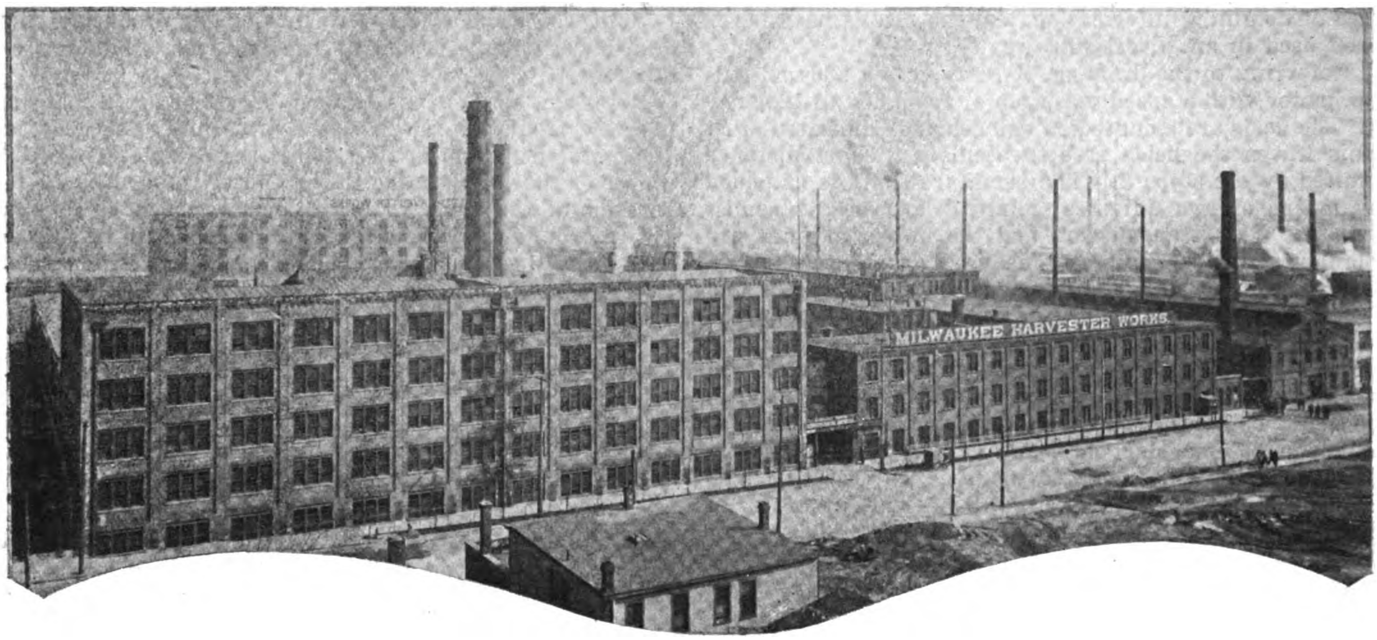
It will be noted that in using this machine the indicated efficiency is lower on account of losses in transmission, ball bearings, universal joints, worm bearings and oil splash. However, it is believed that these losses are very small.

SUMMARY OF TESTS

Test	R.P.M. of Motor	Motor Torque at 2 Ft. Radius in Lb.	Brake Torque in Lb.	Oil Bath Temp.	H.P. Input	Efficiency, per Cent	Remarks
1	800	104	187 lbs. at 9 ft. radius	186	31.68	89.9	Direct drive through transmission.
2	800	103.5	265.3 at 9 ft. radius	189	31.53	86.34	In third speed through transmission. Total reduction, 13.36.
3	800	103.4	296.2 at 14 ft. radius	185	31.5	86.8	In second speed of transmission. Total reduction, 23.1.
4	800	103.9	528.7 at 14 ft. radius	184	31.65	86.2	In transmission low speed. Total reduction, 41.3.
5	800	52	95 at 9 ft. radius	185	15.84	91.3	Direct drive. Transmission removed entirely.

It is realized that these efficiency values are not excessively high. They are, however, actual and are duplicated under actual working commercial conditions with all the gear products of the Baush company and trucks of the truck company. It is realized, too, that the subject might be treated in a more academic way and the tests might be made more scientifically and much more exhaustively. Indeed, the tests were actually made at speeds varying from the lowest to the highest truck speeds, but the results showed so little variation that they are not considered here. These speeds corresponded to an engine variation of from 280 to 950 r.p.m. It is undoubtedly true that if worm speeds—or, to speak more accurately, rubbing velocities—were greatly increased or decreased above these speeds, there would be a falling off in efficiency. Also, when the load per square inch on the teeth exceeds a certain value there is a power loss. The converse of this is also true. The efficiency of a worm gear depends in a very large measure on the fact that a film of oil always exists between the teeth, separating them and rendering metal contact impossible. The fact of this separation has been proven electrically.

It may be asked why, if the teeth touch only oil and not metal, they ever wear out. They do not wear very much. An automobile worm gear properly installed and cared for need never be replaced. By care is meant that there must always be plenty of oil and it must be changed occasionally, as dirt or chip particles set up at once a destructive wear and the oil may become a very fair abrasive. Also, the supporting bearings on the worm and wheel should be of such size that correct alignment is always maintained.



Turning Out 100 Tractors Per Day

Production System Employed at the Milwaukee Plant of the International Harvester Co.—Details of Machining and Assembling Methods

By P. M. Heldt

THE International Harvester Co., one of the oldest firms in the farm tractor field, is at present manufacturing four different tractor models, of which one, the Titan 10-20, is made completely in the Milwaukee works. Only four parts used on this tractor are purchased from outside concerns, namely, the mechanical oiler, the magneto, the chains and the spark plugs, every other part being made on the spot. The plant covers a site of 37 acres and employs in the neighborhood of 5000 men. Not all of the ground is covered by buildings, but every bit of it is used for one purpose or another, as the yards and spaces between buildings are stocked with raw material, parts in process of manufacture or completed machines. At the present time the plant runs on a schedule of 100 tractors a day, but this is constantly exceeded and the actual daily production is generally from 106 to 108 machines. Not all of the plant is devoted to tractor work, however, as farm engines and cream separators are also being made, but tractor production absorbs from 75 to 80 per cent of the entire capacity. The International Harvester Co. has been manufacturing tractors for 10 years, and the Titan 10-20 model has been turned out without important changes for about three years, so the concern has had time to fully develop its production methods.

One of the most important departments in a plant of this kind is the iron foundry with its subsidiary departments, represented by the core room, pattern storage vault and chipping room. The foundry of the Milwaukee plant of the International Harvester Co. is 148 ft. wide by 779 ft. long. Its location with respect to the other departments of the plant is shown by the accompanying general plan. In this department of the works, including the core room and shipping department, about 1100 men are employed. An idea of the capacity of the foundry may be gained from the fact that on March 5 last 360 tons of iron were poured, and during the month of January 7777 tons.

The company takes particular pride in its new core room, which has been in full use only about eight months. The basement under this room serves for sand storage. It is about 25 ft. high, and the sand is brought into it by means of 3 belt conveyors under the ceiling. The sand is shoved off the belt by means of deflectors or boards extending at an angle across it. Back of the sand storage room there is a passage with a number of openings in the wall, through which sand of the different grades can be withdrawn even when the room is practically full. The openings are closed by slightly inclined planks, which slip into grooves in the door frame. These prevent the sand from sliding out through the openings, and can be readily removed one at a time.

In making the core mixture, all of the materials used are dumped into a hopper, whence they are elevated by means of a bucket elevator, from which the mixture drops into another hopper, which feeds it into a revolving screen. This screen is of ½-in. mesh, and all the material that does not pass through this screen is separated out. This material is not thrown away, however, but is ground, and is then fed into the hopper again. Directly below the screen there is a mixer with agitator arms. While the dry materials entering the mixture, including the sand and rosin, are conveyed to the mixer by the elevator, oil is fed into it directly. The mixer delivers the core mixture to an elevator below it, which carries it into the core room upstairs. There are two of these power mixers.

Ordinarily core sand is used only once, but on account of war conditions and the restrictions on means of transport, the International Harvester Company breaks up all its old cores, grinds the material up in a machine with manganese steel rollers, mires it with fresh oil, sand and rosin and uses it over.

The furnaces for heating the core ovens are located in the basement, and the heat is carried up to the ovens through a large flue. A pyrometer of the indicating type, so arranged that it can be connected with any of the thermo-couples in the 32 furnaces, is located on the wall and can be made to instantly show the temperature of any of the ovens. The core-

racks are made of angle steel and tubing. They are so designed that an electric industrial truck can be driven under them and then raise the rack by means of a power lift about 8 in. off the floor. When the core maker has completed a core, he places it on a rack behind him, and as soon as the rack is full along comes an electric truck and takes it away. About one-third of the workers in the core room are women, who do all of the lighter work. The core makers work on benches, and above these benches there is a runway along which the sand is moved by means of wheelbarrows. Over the bench of each core maker there are two hoppers, for two grades of sand. Only metal core boxes are used, and at the present time core making machinery is being installed. An underground passage connects the core room with the foundry.

Unloading Pig Iron

All pig iron is unloaded from the cars into large outside bins, and scrap steel and iron are also loaded into bins in the yard. This material is handled by means of an electric traveling crane with electromagnet. The crane runs the whole length of the yard and has a capacity of 10 tons. The capacity of the magnet is 3000 lb. of pig iron or 1600 lb. of scrap iron. This crane deposits the pig iron and scrap iron on the charging platform for the cupolas outside of the building. On this charging platform the pig iron and scrap iron are loaded into dumping cars, which are dumped into the cupolas by means of air hoists. For unloading sand and coke from railroad cars, so called clam buckets are used in connection with the crane. Every bit of pig and scrap iron that goes into the cupolas is weighed. A track runs the whole length of the charging platform, with two scales on wheels upon it. The track is sunk below the level of the platform, to such a depth that the scale platform is level with the loading platform. The dumping cars are loaded outside the building, are pushed on to scales, and then are moved on toward the cupolas.

There are 6 cupolas in all, in 3 sets of two, but not more than four are ever in use at one time. This gives opportunity for making the necessary repairs, such as relining with fire brick. The usual charge consists of one half pig iron and one half scrap iron, but in one of the cupolas a special mixture with a higher percentage of pig iron is melted. Every time a change is made in the charge of the cupola, a test bar is taken and given to the chemist to analyze.

The foundry, as may be imagined from the dimensions given in the foregoing, is an immense structure, and has a craneway running its entire length, upon which there are three electrically operated cranes. In addition to this, there are eight wall cranes. All of the small work is done on a balcony, which is half the total width of the foundry.

In addition to the overhead traveling crane and the wall cranes, there is installed in the foundry a narrow gage railway on which heavy material can be moved with the least effort. Each group of men in the foundry is provided with an air hoist for lifting molds, patterns, and castings, and for use in pouring. The bigger molds are poured directly from the car ladles from the cranes, while hand ladles are used in pouring the smaller ones. In the medium heavy work each man is provided with an air hoist, so it is not necessary for him to wait for the crane to come around. All heavy molding is done by means of molding machines, in connection with which pneumatic tamping is used.

Up to the present all the chipping, tumbling and grinding has been done at one end of the foundry, in a mill room partly separated from it, but another mill room is now being installed at the opposite end, so the castings will not have to be transported the whole length of the foundry.

Repair Shop for Foundry Equipment

At the north end of the foundry there is a general repair shop for foundry equipment. All castings leaving the foundry are weighed on a scale at the point where they leave the tumbling room. They are also counted. Adjacent to the foundry repair shop there is a storage room for obsolete patterns. The Milwaukee plant of the International Harvester Co. began in 1906 to make farm engines. Many of the designs which have been produced in the plant since that time

Multiple spindle drills working on gear case

have become obsolete, but all patterns are kept, and the plant is in position to furnish repair parts for any machine ever turned out by it. The patterns are stored on racks which are lettered, and each shelf carries a number. A record is kept of all patterns and where they are stored, by means of which it is an easy matter to locate a pattern whenever it is required.

At the north end of the foundry there is a store room for current patterns. In the foundry only metal patterns are used, but all master wood patterns, from which the metal patterns were made, are preserved. The main foundry has a sawtooth roof, and is well lighted. For night illumination there are clusters of nitrogen lamps in the balcony, and single 800-watt nitrogen lamps in the main foundry.

The tumbling and chipping room is located at the south end of the main foundry. It is equipped with disk grinders which take off all the burs from the castings as they come from the molds. Every casting leaving the foundry is inspected, and all of the heavier castings are tumbled on the main floor.

Forge Shop

A department of almost equal importance as the foundry is the forge shop, which measures 101½ ft. in width by 474 ft. in length. All of the large ring gears employed in the Titan tractor are made from forged blanks which are forged in an upsetting machine or bulldozer. All material under 5 in. in diameter is sheared off cold. At one end of the forge shop the wheels are made. The rim material, cut to the right length and punched with the requisite number of holes, is delivered to the plant from outside. The first operation on the blanks is to roll them into circular form. Next the ends are riveted together and then the rims are assembled with the hubs and spokes, which is done in a jig. In joining the ends of the rims together, a couple of bolts are first put in and then the rivets are put in place, and headed by means of air riveters. In the forge shop a great many operations are being carried on, such as the forging of the front axles, gear blanks, crankshafts, connecting-rods, etc., but the equipment of drop hammers, steam hammers, bulldozers, etc., is the same as found in any large forge shop. Adjacent to the forge shop is the heat treating department in which both forgings and castings receive heat treatment. The piston castings, for instance, are annealed in order to relieve cooling strains. All forgings, such as the crankshaft, connecting-rods, etc., are submitted to a heat-treatment to refine their molecular structure, and thus to improve their physical properties.

Machine Shop

The machine shop comprises one single-story structure, 100 ft. wide by 392 ft. long, and at the end of same a six-story building in which most of the lighter work is done. On the upper floor of this six-story structure all of the automatic screw machines are installed. It is interesting to note that the company makes all of its taper pins and similar parts. It was noted that a color scheme of marking is used to distinguish steels of different carbon contents. The automatics are set in the usual way at an angle, so that the bar stock projecting from the head stock of one machine passes by the adjacent one. One of the most interesting machines in this department is an automatic for threading the ends of studs. These studs are used in considerable number for holding the engine cylinders, cylinder heads, etc. The studs, threaded on one end, are fed automatically through a hopper. A chuck clamps the threaded end and then a self-opening die cuts the thread on the other end. Then the die opens and a new stud entering the chuck pushes out the finished one. The first two operations on the studs, that of threading one end, and that of cutting off the stock to the right length, are performed in an ordinary automatic. An idea of the capacity of the special machine for threading the last end of the stud may be gained from the statement that six ½ in. studs with ¾ in. length of thread can be finished per minute.

In all of the automatic screw machines, a constant stream of oil is played on the work, and a great deal of oil naturally adheres to the shavings. About 90 per cent of this oil is recovered in a centrifugal oil separator. The shavings are shovelled into a basket in this separator, which is spun at great speed for two to three minutes, and when the shavings are removed from the machine, they feel absolutely dry. About 8 bbl. of oil is thus recovered each day. Sawdust is used on the factory floor below the automatics to soak up any oil that may leak from the machines.

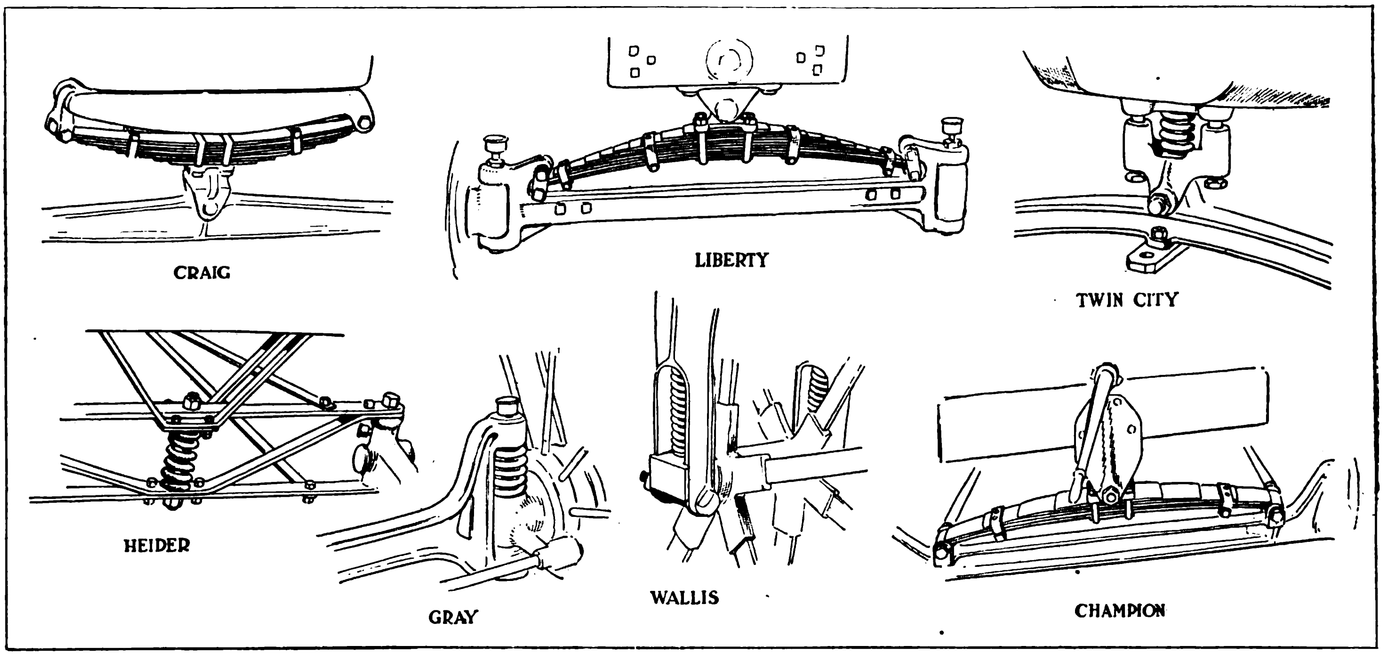
Boring cylinders in vertical boring mill at International Harvester plant

Spring Suspension of Tractors

Both Plate Springs and Coil Springs Used—Spring Suspension of Front End Fairly Common, of Rear End Rare—Sketches of Different Designs

By P. M. Heldt



The above sketches were made by an AUTOMOTIVE INDUSTRIES *artist at the recent Kansas City tractor show and include nearly all the front suspensions seen*

THERE are just two causes of wear and deterioration in tractors, the same as in other types of vehicles—friction and shock. Much has been done to minimize friction. Ball and roller bearings are being used more and more in tractor design, and lubrication means are also receiving close attention. But little has as yet been done to protect the mechanism against shock. It is true that when a tractor travels over soft ground it is really cushioned by the soil and does not require spring suspension to protect it. Whatever vibration may be caused by lack of balance of the engine would not be alleviated by springs but, on the contrary, would be rather aggravated thereby, because with spring suspension the mass on which these vibrating forces act would be cut down and the amplitude of vibration would be increased in proportion. The remedy for this sort of vibration has to be sought in careful balancing of the engine.

Tractors, however, often are required to travel over hard ground and sometimes even over stony roads. This causes a very severe vibration of every part, if no spring suspension is provided. The vibration is a good deal stronger than in a horse-drawn truck, for instance, as the truck usually has wheels of somewhat larger diameter and the wooden wheel absorbs most of the high-frequency, low-amplitude vibration.

Vibration is detrimental in that it tends to loosen joints and to crystallize the material of the parts chiefly affected by it. The force of the shocks produced when a moving vehicle strikes an ordinary road obstacle is greatly reduced by spring suspension. When a moving body strikes a heavy rigid body the force of the impact depends on the inertia of the moving body and on its speed. In the case of a spring suspended vehicle the obstacle is struck directly only by the non-suspended part, and it is chiefly the mass of this part which determines the force of the blow. The spring suspended part will not be deflected from its course as much or as abruptly as the non-suspended part and, while it contributes to the shock, it does so in a much lesser degree than if it were rigidly mounted on the axles.

Spring suspension of the front end of the conventional tractor with rear drive does not involve any structural difficulties. Moreover, spring suspension of the front end is more necessary than spring suspension of the rear end, because all or nearly all of the more delicate mechanism, such as oiler, magneto, governor, etc., is located nearer to the front than to the rear axle.

On creeper type tractors the forward end is practically always spring suspended. Owing to the low pressure per square foot of ground contact with the creeper type, the latter undoubtedly has more need for spring suspension. The suspension sometimes takes the form of a cross spring by which the engine supporting frame is carried on the truck. In other cases coiled springs are used.

There are three different methods of suspending the front of a wheel type tractor. In a few instances, half-elliptic side springs are used, as in passenger cars and trucks. However, it is generally considered that this construction does not offer sufficient flexibility for farm tractors. The centrally pivoted axle is so common in farm tractors that it may almost be considered standard. If the springs could be made as flexible as automobile springs, the side springs might do, but such is not the case. There being springs only at the forward end, this already reduces the magnitude of the ground warp to which the tractor will readily accommodate itself by about one-half.

The older type of spring suspension used on wheeled trac-

tors is that employing coiled springs. As far as the qualities of suspension are concerned, there is certainly very little difference between the coiled spring and the flat leaf spring. With the former there is no equivalent to the interleaf friction of the latter but at the low speeds at which tractors operate the rebound is not a factor of importance, so this does not matter. The objectionable feature of the coiled spring is that it has to be paralleled with a sliding pin or sliding pins through which the drive can be transmitted from one to the other of the parts separated by the spring.

To prevent undue wear of these pins and their guides they must be well lubricated, and inasmuch as these parts are directly exposed to the dust raised by the front wheels this is practically impossible. The closer the sliding joint is to the wheel the worse the conditions. If the sliding pin and guide could be surrounded by a leather boot filled with grease, it might be possible to get tolerably good wear out of such constructions, but leather boots are not in favor with tractor designers, and with some types of spring suspension they would be practically impossible.

Of course, wherever there is a spring suspension there must be sliding motion. But while in the case of guides parallel to coiled springs the motion is equal to the spring play, with leaf springs pivoted or shackled to the frame or axle, the motion on the surface of the shackle bolt will be only about one-twenty-fifth of the spring play. It is obvious that the smaller the range of motion the less will be the amount of wear on the pins or bolts. Moreover, a shackle pin or spring bolt is naturally much better protected against dust and dirt than a pin sliding in a guide with a range of motion of ½ in. or more. Therefore, it would seem preferable to use plate springs owing to the better wearing qualities of the connection.

As regards the range of spring action, this can be made comparatively small, owing to the low speed. The stiffer the spring the higher its natural rate of vibration and the better it is adapted to absorb shocks following one another at short intervals. Of course, it is not to be understood that the stiffest spring is the best, as this would logically lead to the conclusion that no spring at all would be best of all. The point is that as compared with motor trucks, and especially passenger cars, the vibrations of the running gear, which the springs must prevent from being transmitted to the frame, are essentially of short period. A compression of 1 in. under the dead load upon it and clearance for a slightly greater additional deflection under shock would meet the requirements. The obstacles causing these vibrations, in the case of a motor truck or passenger car, are absorbed by the rubber tires.

At the Kansas City tractor show there were nearly a dozen makes of tractors with spring suspension in front. A large variety of designs were represented, including half-elliptic side springs, half-elliptic cross springs, inverted half-elliptic cross springs, coiled springs on the steering knuckle and coiled springs at the center of the axle. Sketches of some of these suspensions are shown herewith.

Rear spring suspension in tractors is very rare. The chief reason for this is that the transmission of power from a spring-suspended frame to the rear wheels or rear axle involves difficulties. In the few cases where the rear end is spring-suspended it is supported on the axle through the intermediary of coiled springs, the axle moving up and down in a guide slot in the frame itself or in a bracket secured to it. It is figured that the slight range of spring play, although it does change the center distance between bull gear and pinion, does not change it enough to appreciably affect the mesh of the teeth. The driving thrust is transmitted to the frame directly and the torque reaction comes on the bearings of the bull pinion shafts.

Water Injection in Oil Engines

VARIOUS effects of the injection of water into the cylinders of internal-combustion engines are discussed by A. F. Van Amstel in the columns of *Engineering*. He says the misleading statement has been published that the use of water injection for obtaining increased power has been proved to be attended with injurious results to the engine because the sulphur present in the oil combines with the water and forms sulphuric acid, which rapidly eats away cylinder walls, pistons and piston rings.

The fact is, however, that the worst fuel does not contain more than a maximum of 2 per cent of sulphur and at the same time contains at least 6 per cent of hydrogen. This hydrogen combines with oxygen of the air and forms water, a part of which latter combines with the sulphur and more oxygen, forming sulphuric acid, according to the equation:

$$2S + 3O_2 + 2H_2O = 2H_2SO_4.$$

So 4 parts of hydrogen form sulphuric acid by combining with 64 parts of sulphur and 128 parts of oxygen, the atomic weights of the said elements being (rounded off) 1.32 and 16 respectively. Whereas the fuel does not contain more sulphur than one-third of the weight of hydrogen contained in it, it is clear that it is impossible that injection of water can cause the formation of more sulphuric acid than is formed if no water at all is injected. In using oil containing sulphur it is advisable to avoid the use of copper or copper alloys, not only in the engine proper but also in the fuel pump and all parts coming in contact with the fuel or the burnt gases.

The injection of water into internal-combustion engines is very useful, if it is arranged in a judicious way, because it greatly improves the combustion process by its catalytic action and in proportion as combustion pressure is produced earlier during the working stroke, the mean pressure, of course, is higher, so more power is obtained from the same quantity of fuel. The water vapor prevents the combustion from proceeding slowly and tardily, and obviates the possibility of formation of soot and other products of incomplete combustion. This catalytic acceleration of combustion processes by water vapor is very remarkable.

Dixon observed that a completely dry mixture of carbon monoxide and oxygen cannot be ignited, neither by a red-hot spiral nor by induction sparks. After adding water vapor, however, the mixture becomes explodable. A carbon monoxide flame goes out in dry air. Dry nitro-cellulose detonates with a velocity of 3750 m. per sec., whereas wet nitro-cellulose burns with a speed of 6000 m. per sec.

The Motorcycle Outlook in Great Britain

THAT there will soon be a great shortage in motorcycles in Great Britain is the opinion of Duncan Watson, managing director of the Harley-Davidson Motor Co., Ltd., of London, at present in this country. Says Mr. Watson:

"Of course, there is an absolute embargo on the importation of American motorcycles, automobiles and motor trucks into the British Isles at the present time. It seems to be the consensus of opinion, however, that within a few weeks this embargo will be partially lifted so that the British importers can bring in a limited number of American motor products. I believe that gradually the embargo will be further lifted by a process of rationing. It is not to discourage American competition that the present embargo is in effect. I want to emphasize this point because the impression seems to have gained ground that the embargo exists solely for the protection of the British manufacturers.

"As a matter of fact, most of us feel that the embargo is being used to hold up the rates of exchange more than for any other purpose. That is to say, that if the embargo was lifted completely there would be a tremendous in-rush of American-made products, which would create an overwhelming trade balance which would be detrimental to the rate of exchange, as you can readily see.

"The British post-war demand for motorcycles will not be satisfied until one million and a half motorcycles are put into the British Empire, one million of which will probably be absorbed in the British Isles alone."

Italy's War Vehicles Traveled to France by Own Motor Power

Cars and Trucks Took Road Over Alps Through Mont Cenis Pass—Airplanes Made Flight at Height of About 12,000 Feet

By W. F. Bradley

PARIS, March 19—The finest example that could be obtained of the value of roads to military operations is furnished by the passes over the Alps between France and Italy. There are three railroad lines connecting France with Italy, and the most important French line goes over the Alps by the Mont Cenis pass.

Very early in the war Italy became an important factor in furnishing motor vehicles to the allied armies, and the only practicable railroad route by which these could be delivered was via the Mont Cenis pass. It was not long before the insufficiency of this route was manifest and arrangements were made to make deliveries of automobile material by road whenever possible. There is a very fine road over the Mont Cenis pass. Italian automobiles for the French army, being practically all built at Turin, were delivered by road over Mont Cenis pass. Fiat was the first to start this service. From Turin to the French frontier station, on the eastern slope of the Alps, the distance is not more than 80 miles, but practically twenty of these constitute steady climbing, and the altitude attained is 7500 ft. Nearly every day a convoy of trucks or touring cars, which had previously been accepted by the French military commission, left Turin in charge of civilian drivers, climbed over the Alpine pass and were delivered at one of the French forts at Modane, about 6 miles inside French territory. From this point the civilian drivers returned to Italy by train and the following day came out with another and similar convoy.

All the roads over the Alps are snowed over from December to March or April. The authorities soon realized that they could not afford to lose these roads throughout the winter; consequently arrangements were made for gangs of soldiers to work on Mont Cenis pass in order to keep this road open for about two months of the closed period. At the beginning of the winter of 1918 all arrangements had been made for French territorial troops and 3,000 German or Austrian prisoners to keep this road free of snow throughout the whole of the year, so that had the war continued there would, for the first time in the history of the world, have been a stream of traffic across Mont Cenis throughout the winter.

After the disaster to the Italian army at Caporetto in November, 1917, the stream of traffic across the Alps changed in direction, for it became necessary for the British and the French to send temporary reinforcement into Italy. The two railroad lines were worked to the limit of their capacity; trains ran through from France to Italy at intervals of about 20 minutes, unloaded, and returned immediately, the authorities refusing to allow them to wait for a return load, so great was the need of sending men and supplies into Italy.

Italy supplied not a few airplanes to the French and American armies in France. At first these were shipped by rail, but it was soon realized that this method was slow and unsatisfactory. After a few experimental flights had been made over the Alps it was decided to send all planes from Italy to France on their own power. Most of these planes were built at Turin and Milan. Starting from this point they had to rise to a height of about 12,000 ft. in order to clear the top of the Alps safely. The necessary height was obtained while the planes were over the valleys, and the crossing was never attempted unless the safe height had been reached. As a precaution, the Italian authorities constructed a big landing ground on the top of Mont Cenis, 7000 ft. above sea level. A huge white cross was marked out in the ground and served as a guide to the pilots. In case of any accident which made it impossible for the pilot to continue his flight over the Alps into France he could always plane down to this Alpine landing ground.

Liberty Line of Wisconsin Engines

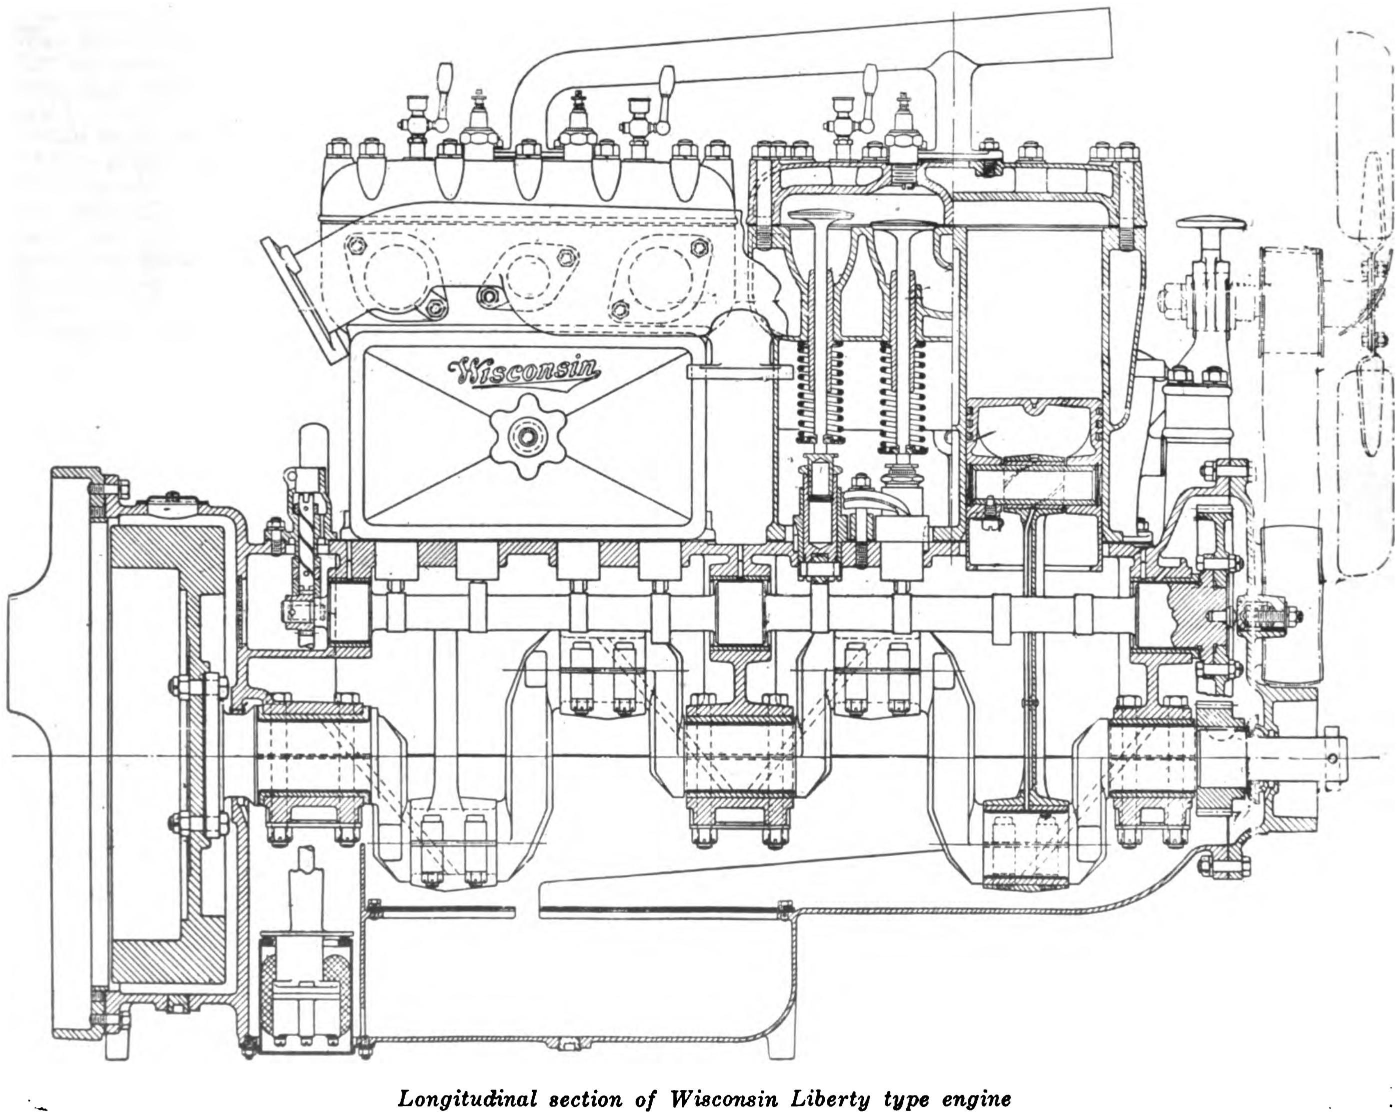
Principal Features Include Unit Power Plant Design, Aluminum Crankcases, Pressure Lubrication and "All-Steel" Three Point Support

A NEW line of four-cylinder engines, to be marketed under the trade name "Liberty," has been developed by the Wisconsin Motor Mfg. Co., Milwaukee. The line includes seven different types, viz., Type RAU, 4¾ x 6 in.; RBU, 5 x 6 in.; TAU, 4 x 6 in.; UAU, 4¼ x 6 in.; VAU, 4½ x 6 in.; EAU, 3¾ x 5 in.; BAU, 4 x 5 in. Of these different models the first two have their cylinders cast in pairs, with detachable cylinder heads, while the last five have their cylinders cast in blocks with solid heads.

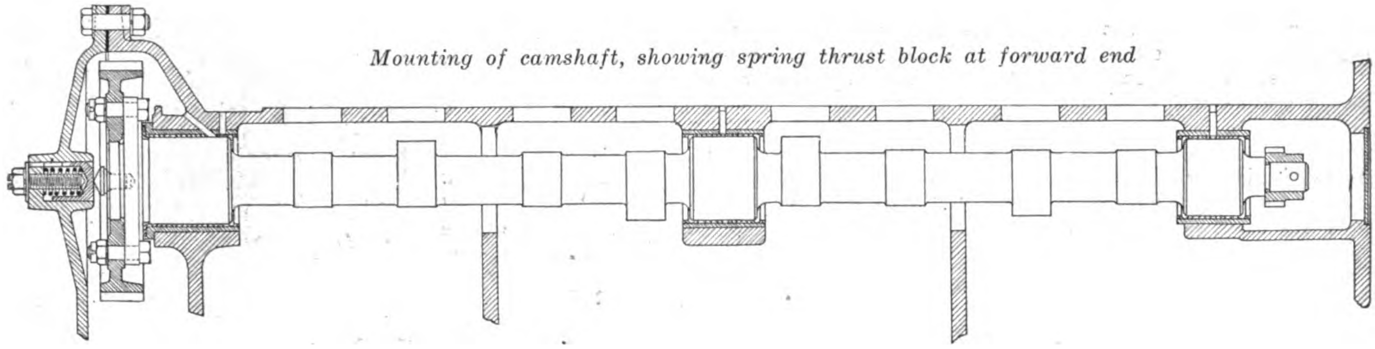
Taking up the two larger models first, they have L-head cylinders, which are bolted to the aluminum crankcase. These engines are specially designed to handle the lower grades of fuel which are now offered on the market. The crankshafts are made of chrome nickel steel, 2¼ in. in diameter on the crankpin, and 2¼, 2 5/16 and 2⅜ in. diameter on the front, center and rear main bearings respectively.

The crankcase is made of aluminum, with massive webs supporting the bearings. At the forward end there is a large, combined breather and oil filler, and an indicating oil gage is located on the same side of the case at the rear. As indicated by the "U" in the type designation of the engine, these two models are of the unit power plant type, and the flywheel is enclosed in a bell housing which is cast integral with the crankcase. The three point system of suspension is used, and special emphasis is laid on the fact that the engine has an "all steel" suspension. At the front it is supported on a trunnion bearing formed on the timing gear housing cover, while at the rear there is a cast steel or malleable supporting beam which is bolted to the bell housing. It is pointed out that dependence upon aluminum for support is undesirable, not only on account of the wear in the holes for anchor bolts, but also on account of breakage of the aluminum arms due to vibration. In case one of the steel arms should be broken in an accident, it can be very cheaply replaced.

The camshaft is formed with very large diameter bearings, and can be withdrawn from the forward end of the engine. To a flange forged integral with the camshaft at the forward end is secured the camshaft driving gear. A spring pressed



Longitudinal section of Wisconsin Liberty type engine



Mounting of camshaft, showing spring thrust block at forward end

plunger of hardened steel presses against a button head screw in the forward end of the camshaft, and presses it against the thrust flange of the forward bearing.

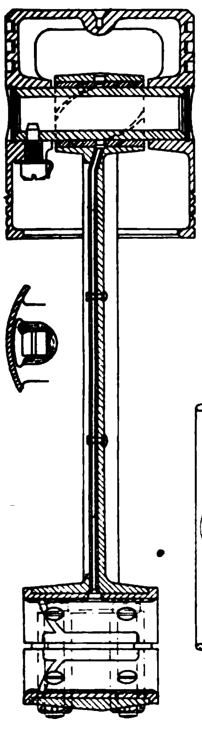
Valve tappets are of the roller type, of extra large diameter. The tappets, rollers and roller pins are hardened, to insure long life to these vital parts. The guides are of cast iron and are held in position by crabs and studs. This entire mechanism is inclosed by an oil type cover plate, which keeps out the dust. Openings are provided into the crankcase so that the oil vapors from the latter rise to lubricate the tappets and valve stems. The timing gears are cut with helical teeth, of wide face. The pinions of the timing gear are made of drop forgings, heat treated, while the large gear on the camshaft is made of cast iron. All main and connecting-rod bearings, as well as the camshaft, pump, drive shaft and other gear bearings, are of babbitt-lined bronze. Main and connecting-rod bearings are fitted with one-piece laminated shims.

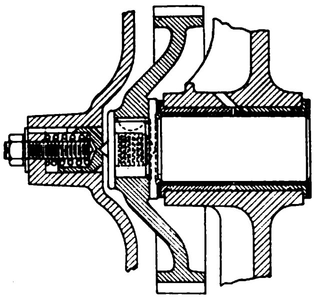
The oiling system is of the pressure type, an oil header being cast in the crankcase, which leads to the main bearings. The crankshafts are drilled, so that the oil is also forced to the connecting-rod bearings, and through tubes on the rods to the piston pins. The oil pump is bolted to the upper half of the crankcase and extends down into the oil reservoir. A large screen surrounds the oil pump and can be removed for cleaning without disturbing the pump or the oil pan. A relief valve is provided on the pump, so that a constant pressure is maintained.

Combined inlet and exhaust manifolds are used, and are made of cast iron. They are so designed that the heat of the exhaust will vaporize the low grade of fuel which must now be used. To insure economical use of fuel, the inlet passage is kept down in diameter.

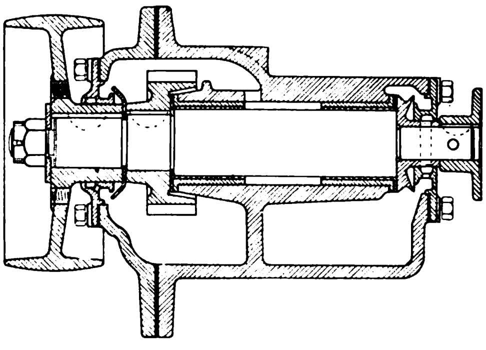
A substantial fan drive is provided, a 2-in. belt being used, which transmits plenty of power for the larger fans necessary for truck and tractor service. Provision is made for mounting electric generators and starting motors, the crankcase being designed with S. A. E. standard flanges. The locations of these accessories, as well as those of the carbureter and magneto, are so chosen as to leave all mechanism very accessible. An inspection of the drawings herewith will illustrate this, and will also bring out the fact that mounting of the steering gear on either the right or left side of the engine was provided for in the location of the various accessories. A drive is also provided for the various commercial governors, and manifolds can be furnished to accommodate same.

The second set of sizes, which are 4 x 6 in., 4¼ x 6 in., and 4¼ x 6 in. cylinders, follow very closely the RAU and RBU models just described except that they have block-cast cylinders and that the valve tappets are of the mushroom instead of the roller follower type. All of the dimensions are,

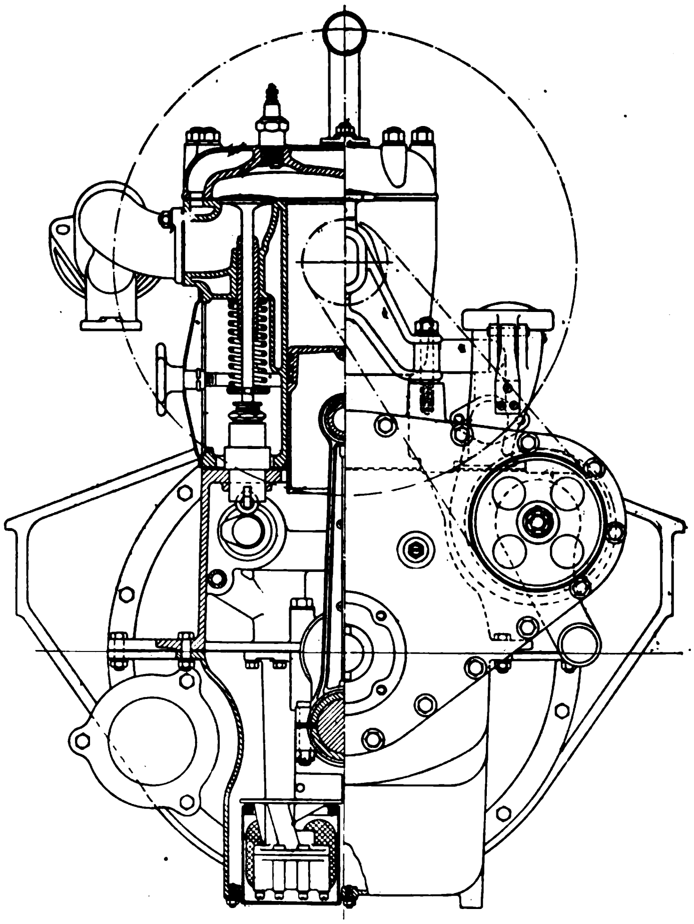




Spring thrust block on idler gear



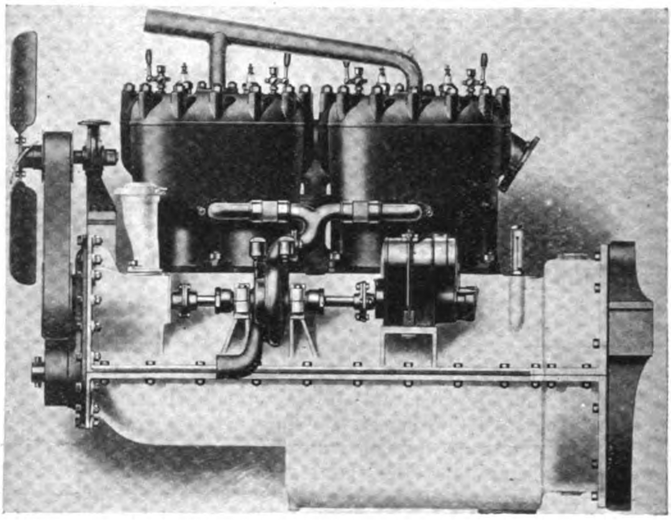
Left—Piston and connecting-rod. Right—Accessories driveshaft mounting



Cross section through cylinder

of course, reduced in proportion, the crankshaft, for instance, being 2 in. in diameter. It, however, is also made of chrome nickel steel, and the same material as in the larger models is used throughout.

In a general way the two smaller models, of 3¾ x 5 in. and 4 x 5 in. cylinder dimensions, also follow the above specifications. The principal exceptions are that the cylinders are cast in blocks, with integral heads, and that mushroom tappets are used. No relief valve is fitted to the oil pump on these smaller models, as the pump is smaller and does not require a pressure relief.



Wisconsin engine

AS an evidence of the necessity which exists for immediate action, the latest published returns show, say the British Industrial "Safety First" Association, that, in 1914, 969 persons were killed and 147,045 were injured by accidents in workshops and factories alone, a large proportion of which would undoubtedly have been prevented had those who became casualties been educated in matters pertaining to their own safety. Millions of dollars paid in compensation, and huge sums of money lost to workers as wages, might have been saved and utilized to better advantage.

Oil-Shale Deposits in the United States

MUCH attention is now being paid to the oil-shale deposits in the United States, and the possibility of exploiting them to take the place of the liquid oil supply in due course, as it is estimated that the latter source of supply will be exhausted in about twenty years' time. Oil-shale deposits are found in several parts of the United States, but those in Colorado and Utah are the most extensive and have so far received the greatest attention. The following facts regarding the nature of oil-shale are taken from an article in *The Engineering and Mining Journal.*

Oil-shale has no oily appearance indicating that it contains free oil, but upon being subjected to heat its organic materials are broken up, and among other things, oil and gas are yielded. The yield varies from 6 to 90 gallons of crude oil per ton of shale. The crude oil distilled may give 7 per cent to 12 per cent gasoline, 28 per cent to 49 per cent kerosene and 39 per cent to 62 per cent residuum. Shale analysis indicates ½ per cent to 3 per cent moisture, 20 per cent to 52 per cent volatile matter and 45 per cent to 80 per cent ash. The asphalt varies from ½ per cent to 4 per cent and paraffin from 2 per cent to 9 per cent.

The by-products of oil-shale are extremely valuable and include gasoline, kerosene, lubricants, enamels, varnishes, paints, rubber substitutes, manufacturing products for glass, pottery and ornamental tiles, dyestuffs, ammonium sulphate, flotation oils and producer gas. The Colorado shale area covers more than 2500 square miles and the Utah area over 3000 square miles. The strata vary from a few inches to 80 feet thick. The yield is from 31½ to 80½ gallons per ton.

In Scotland over 3,000,000 tons of shale are profitably treated annually, but it is only the ammonium sulphate produced as a by-product which makes the business pay. On the other hand, the prospects of the American oil-shale industry should be good, as in Colorado and Utah the shale beds are relatively thick, suitably located high up for gravity transportation, and give a yield of 40 to 50 gallons per ton.

M. & E. Multiple Dry Disc Clutch

MERCHANT & EVANS CO. of Philadelphia, who for many years have been manufacturing the Hele Shaw multiple disc clutch, have recently brought out a new type of dry disc clutch. This is made in two forms, with a single driven disc and with multiple driven discs respectively. The clutch spring does not compress the discs directly, but acts on them through the intermediary of a toggle mechanism. It is claimed for the clutch that it contains very few working parts, is very simple and tool proof, and that it can be very easily disassembled. No adjusting means are provided, and owing to the peculiar construction of the disc compressing levers, a low-pressure spring can be used, thus making the clutch soft-acting. This clutch is recommended for both passenger car and truck use and, although first-class materials and workmanship are embodied in its manufacture, the makers state that it can be sold at a price within the reach of all motor vehicle manufacturers.

The same toggle mechanism that is used with the multiple disc clutch is also used with the single disc clutch. This latter type is made in two designs, one self-contained, the other of what is described as the flywheel type. This single plate clutch is intended for use in connection with engines up to 30 hp. The self-contained type of clutch is adapted for use where the engine and transmission are mounted separately, while the single-plate type is best adapted to unit power plant construction. The shifting collar of all these clutches is fitted with an annular ball bearing.

The Velie Biltwell Tractor

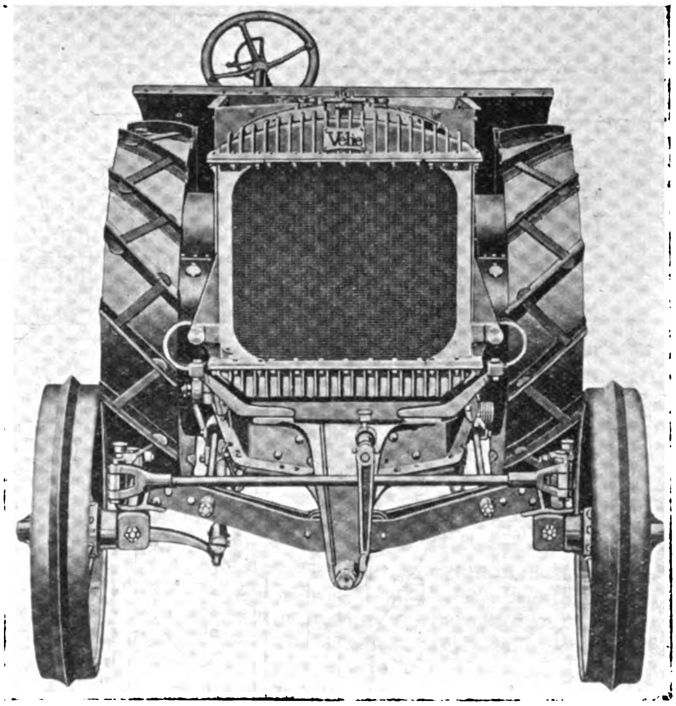
A 3-Plow Machine with Kerosene Burning Engine, 3-Speed Sliding Gear Transmission and Inclosed Bull Gear Drive—Flexible Running Gear with Spring Suspension of Frame in Front

By P. M. Heldt

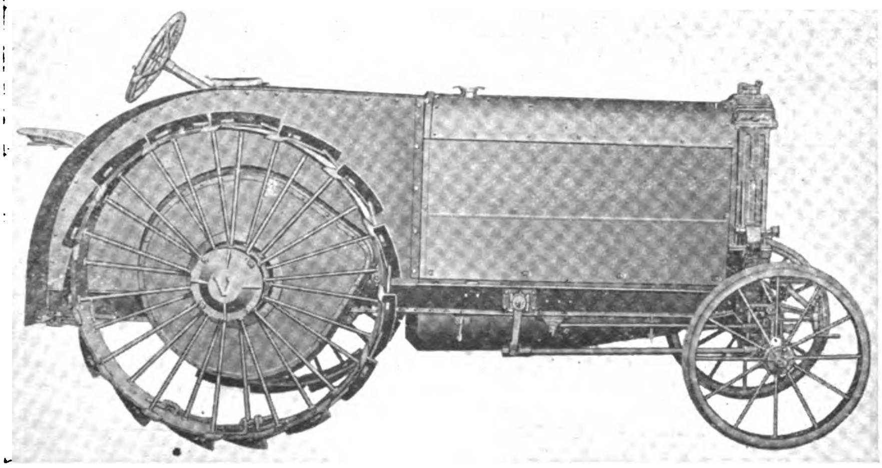
FOR several years past the Velie Motors Corporation of Moline, Ill., has been doing development work on farm tractors, and had it not been for the war, the concern probably would have marketed its first product in this line nearly a year ago. However, in view of the difficulties in the labor and materials fields, and the restrictions placed on the tractor industry by the Government, the Velie corporation decided to suspend manufacturing operations until the end of the war, meanwhile continuing its field tests with a considerable number of machines.

The tractor was exhibited at Kansas City, and is now to be put in production. It must be classed as in line with the most modern trends in tractor design, smooth lines and complete inclosure of all working parts being its outstanding features.

The engine is a four-cylinder type of 4⅛ in. bore by 5½ in. stroke, and the tractor has a 24 hp. rating. The four cylinders and the top half of the crankcase are made in a single casting, while the cylinder head is separate. The engine is specially designed for tractor work, and is of materially heavier construction than the Velie truck engine. It has a crankshaft of 2½ in. diameter, which is supported in three main bearings. The connecting-rod bearings measure 2¼ by 3 in. and the lengths of the main bearings (front to rear) are as follows: 3 7/16 in., 4½ in., 5 11/16 in. The cylinders are of the L-head type, and the valves are completely inclosed. In order to provide for access to the connecting-rod bearings, two large hand holes are provided in the upper half of the crankcase on the side opposite the valves. The valves have a clear diameter of 1 11/16 in. and a lift of ⅜ in. They are operated by means of cams with mushroom type cam followers. Bushed valve guides are used. The camshaft is supported in three bearings, which are quite liberal in size, as may be judged from the following dimensions: Front, 2½ by 2½ in.; center, 2⅜ by 2 3/16 in.; rear, 2 3/16 by 2½ in. Non-Gran bronze bushings are used for the camshaft bearings, while the crankshaft and connecting-rod bearings are of the bronze back, babbitt-lined type. The bronze used for these bearings is of the "Ring true" brand, and a special tin babbitt is used. Non-Gran bronze is also the material for the piston pin bushings. The pistons are of conventional design, with three ¼-in. rings at the upper end, and three oil grooves at the lower end or skirt. The piston pins are hollow, hardened and ground, and are held in position by pin screws. H-section drop forged connecting-rods are used, and the caps are held in place by nickel steel heat-treated bolts. As may be seen from the sectional views of the engine herewith, all of the main bearings are completely supported from the upper half of the crankcase. The camshaft is driven from the crankshaft through a pair of helical gears, and there is an additional gear for the drive shaft. A 23-in. flywheel, weighing 163 lb., is bolted to an integral flange on the crankshaft. Including the carbureter and magneto, the engine weighs 885 lb.



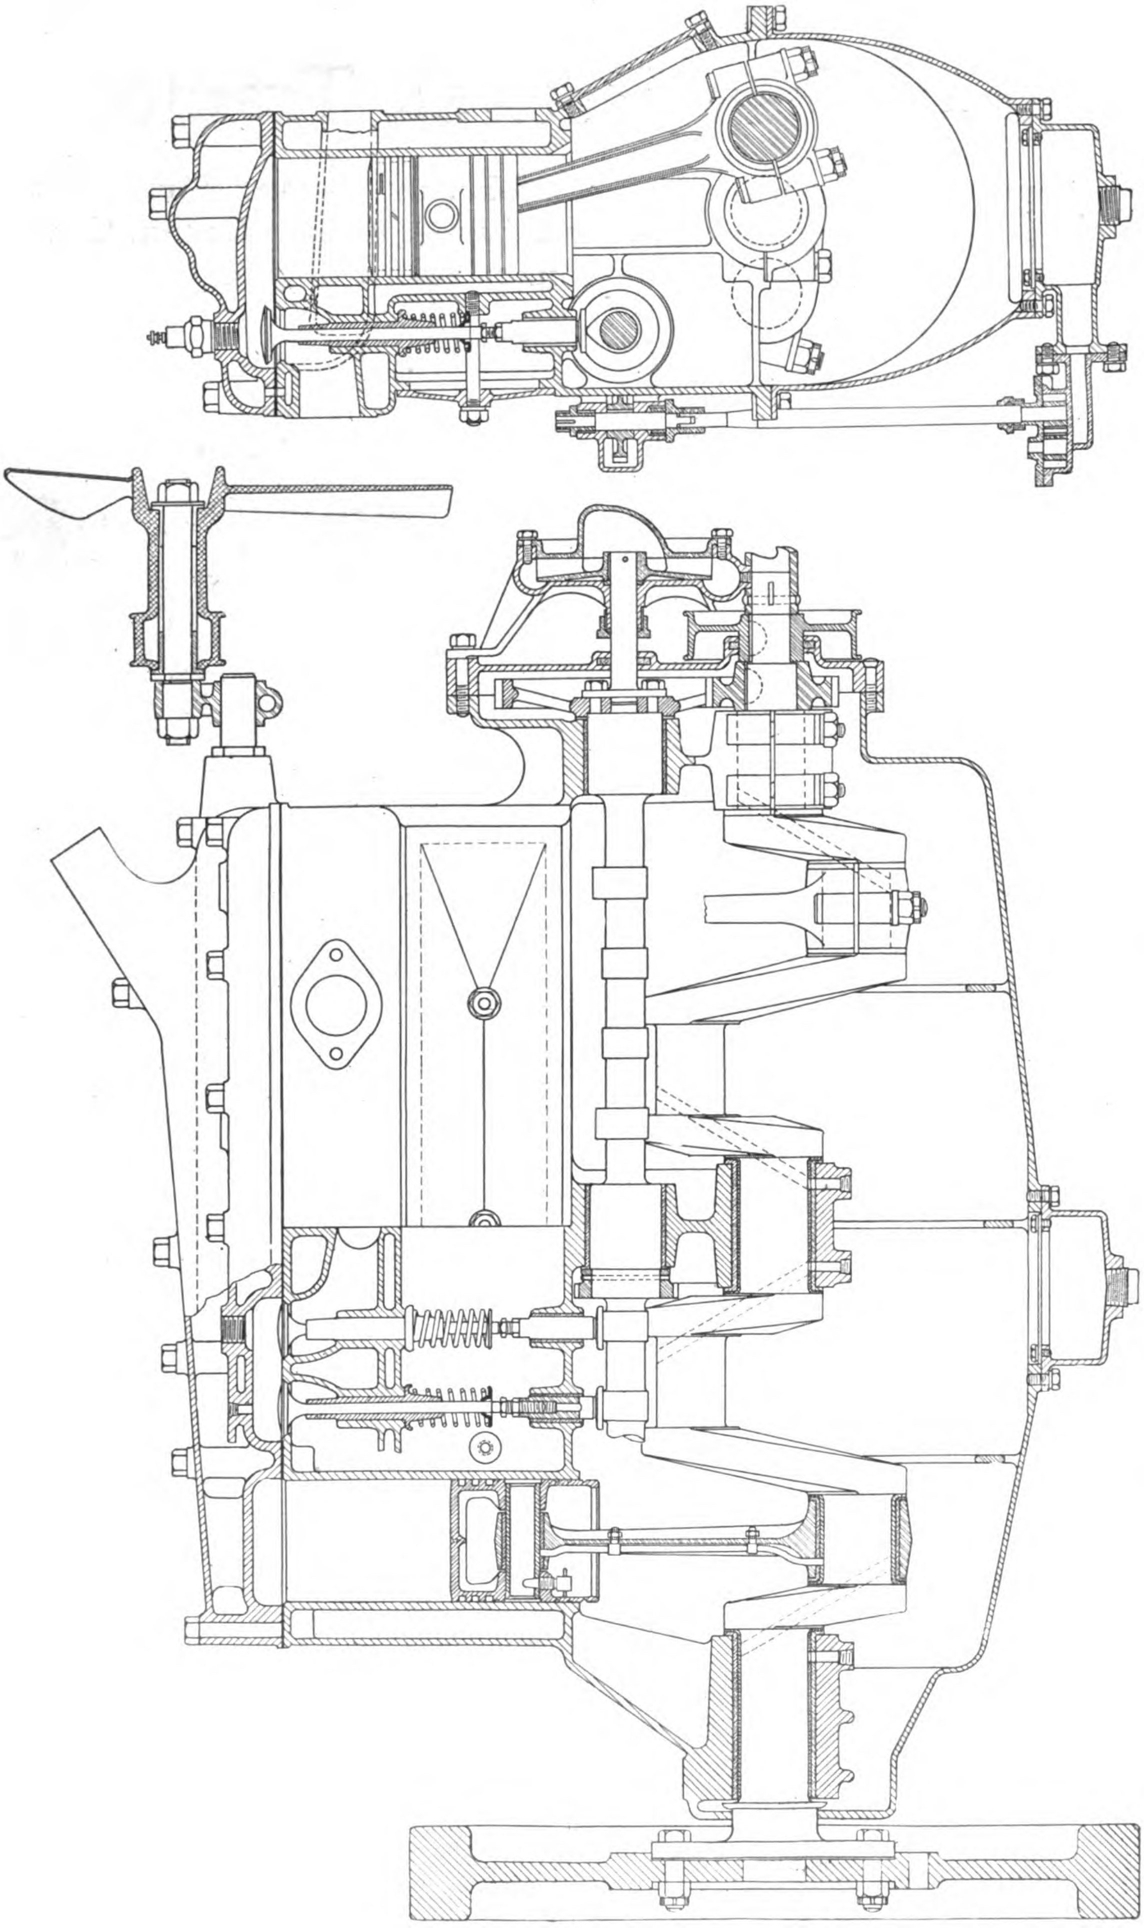
Front view, showing axle mounting, spring suspension of radiator, etc.



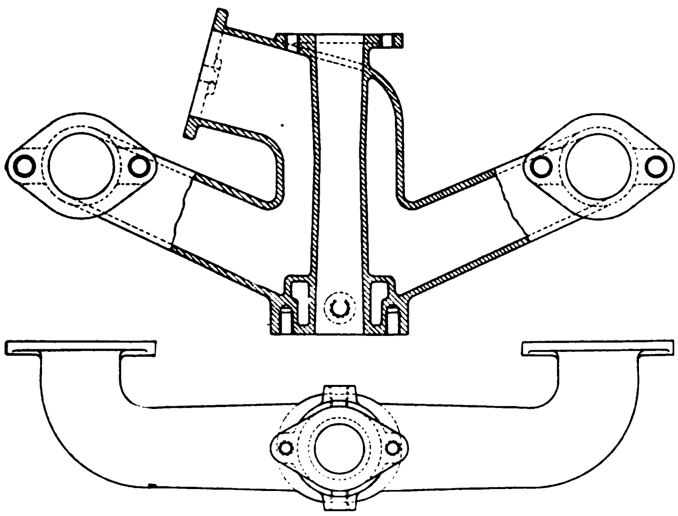
Side view of Velie tractor

Kerosene is the fuel regularly used, and a supply of 22 gal. can be carried in the main fuel tank. There are also tanks for 2½ gal. of water and for 2½ gal. of gasoline. Water is drawn into the cylinders automatically whenever the engine runs under appreciable load. All tanks are of cylindrical form, and made of 16 gage terne plate, with welded seams. The gas-

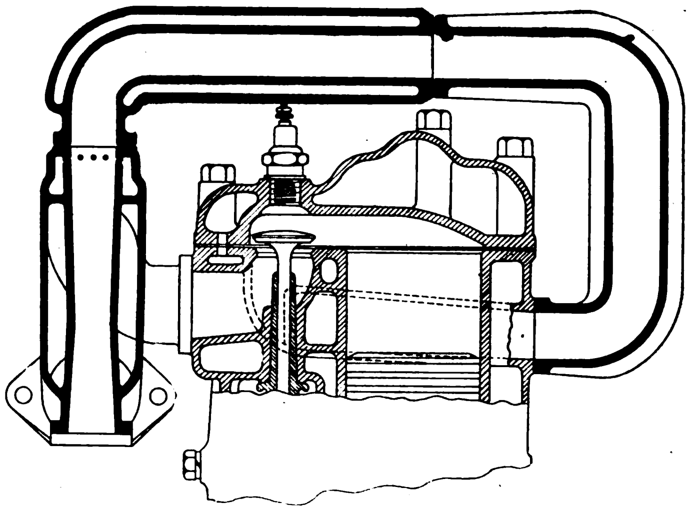
Four-Cylinder Engine of the Velie Tractor



This engine has $4\frac{1}{8}$ x $5\frac{1}{2}$ cylinders, burns kerosene, is pressure-lubricated and is of heavy construction throughout



Combined exhaust manifold and inlet pipe



Inlet passage, partly water jacketed and partly air cooled

oline and water tanks are located under the hood, while the kerosene tank is located in back of the dash, crosswise.

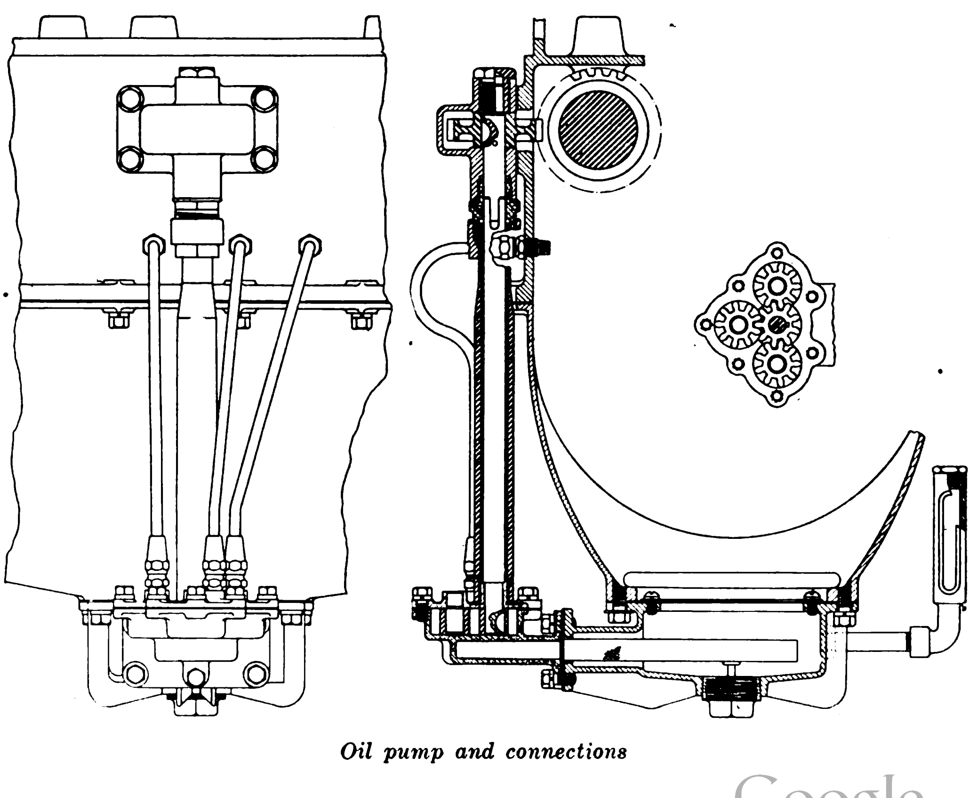
Two Kingston carbureters are fitted, one for starting on gasoline and one for operating on kerosene after the engine has warmed up. There is a three-way valve at the junction of the carbureters with the inlet pipe, so that either one of the carbureters can be shut off completely, or part of the mixture can be drawn from each. The water tank is located directly above the engine, and water passes through a T fitting, clearly seen in the photograph of the engine to the right of the inlet pipe, which fitting also contains a throttling or suction control valve. By means of this suction control valve, the feed of water can be regulated. The water feed is ordinarily so adjusted that from 2½ to 3 gal. of water are used to 20 gal. of fuel. Directly above the three-way valve in the inlet pipe is located the throttle valve for controlling the amount of charge entering the cylinders, and above this valve is an insert in the inlet pipe containing the throttle valve which is controlled by the mechanical governor. Then follows an offset section which brings the inlet pipe somewhat closer to the engine. The upper vertical portion of the inlet pipe is in the form of a venturi tube, and is completely surrounded by the exhaust pipe, except for a short length at the top, which is surrounded by a steam chamber. It is into this steam chamber that the water from the water control valve is fed. From the steam chamber there are a number of jets or outlets into the inlet pipe. An equalizing tube extends from that portion of the inlet pipe surrounded by the steam chamber to the offset portion of the inlet pipe referred to in the foregoing.

The combination inlet and exhaust manifold extends to a height even with the tops of the engine cylinders, and thence a water jacketed inlet pipe extends across the top of the engine to the opposite side. The inlet pipe then drops to the middle of the cylinder block, where it bolts over the end of the inlet passage which extends through the cylinder block between the second and third cylinders. While that portion of the inlet pipe located on top of the engine is water jacketed, that section extending down to the connection to the cylinder block is provided with cooling ribs. A Bennett air cleaner is fitted to the air inlet to the kerosene carbureter. There is a supplementary air valve at the connection of the inlet pipe to the cylinder block.

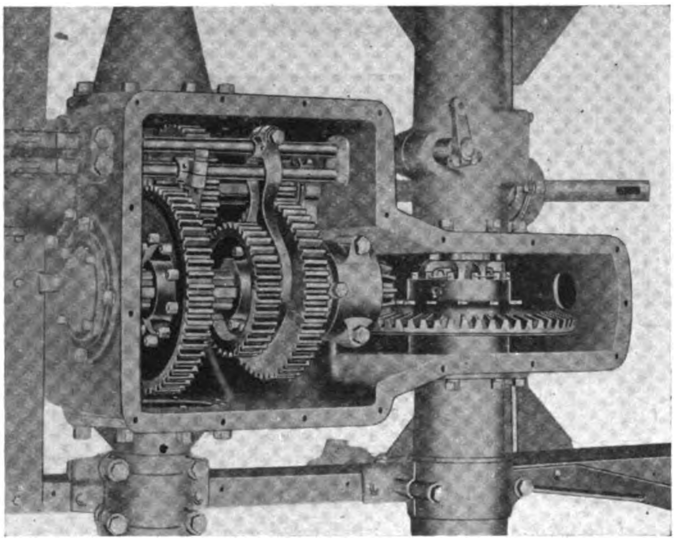
Ignition is by a Kingston high tension magneto, with impulse starter, which is mounted on a bracket cast integral with the bottom half of the crankcase, on the carbureter side.

Design of Cooling System

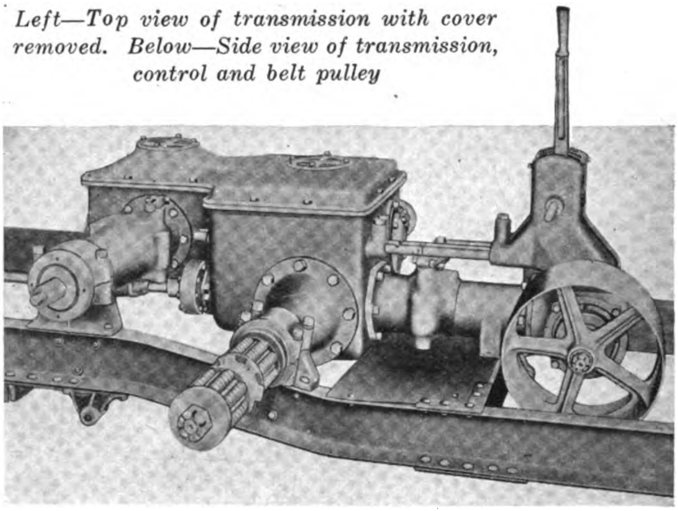
Special attention appears to have been given to the design of the cooling system. It will be noticed from the sectional views of the engine that the jackets extend all the way down the cylinders, and the cooling water is also carried all around the spark plug bosses and the valve seats. A tubular type of radiator, with Bremer core, is used. It has a cast shell and radiating fins are cast on both the top and bottom tanks. In order to protect the radiator against severe shocks, which are inevitable with a machine of this type, it is supported on two scroll springs. Back of the radiator is mounted a four bladed fan, containing a Hyatt roller bearing, and driven by a 2-in. belt. Means are provided for adjusting the tension of this belt. The total water capacity of the cooling system is 7½ gal. The water is circulated by means of a centrifugal pump having a patented flexible mounting. The pump is really mounted on the driving shaft, and has a one



Oil pump and connections



Left—Top view of transmission with cover removed. Below—Side view of transmission, control and belt pulley



point support on the gear case cover, so that it can automatically adjust itself to the position of the driving shaft. Water enters the cylinder jackets at the bottom and leaves at the top. The water jackets are cast with baffle plates which insure circulation to every part.

Force Feed Lubrication

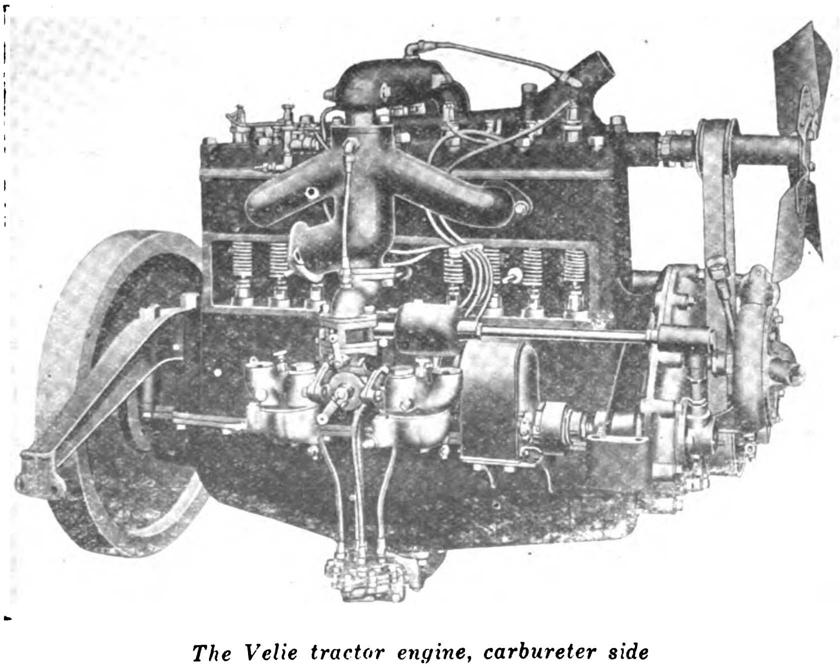
Lubrication is by the force feed system. An oil pump of the gear type is used, and is located at the lowest point of the engine, but outside the crankcase, where it is readily accessible. This pump is driven by a helical gear from the camshaft, through a vertical shaft with tongue and groove joint, just below the gears. The pump is located at the side of the oil sump and delivers oil through outside pipes under 40 lb. pressure to each of the main engine bearings. It is forced through drill holes in the crankshaft to the crank pin bearings, and through tubes leading up the connecting rods to the piston pin bearings. Thus, the lubrication of all the power carrying parts is effected by force feed and the pressure of feed at normal engine speeds is about 40 lb. to the square inch. There is a branch from each main bearing leading to the corresponding camshaft bearing, so that camshaft lubrication is also by force feed. It is recommended that when the tractor is in constant use, the oil should be renewed every forty hours.

A Borg & Beck 12 in. plate clutch is used, and is mounted on the flywheel, being enclosed in a separate revolving drum. The transmission is of the company's own design, and affords three forward speeds in addition to a reverse. It is similar in layout to a motor truck transmission. The two shafts are mounted one above the other, the lower being the primary shaft. All gears are made from forgings of 3½ per cent nickel steel, and are cut with 6-8 pitch teeth, the face widths being 1½ and 1⅝ in. Timken roller bearings are used throughout the transmission. On the ring gear end of the jackshaft a Timken bearing is used, and on the other end a Hyatt. There are two hand holes in the top of the transmission case. All moving parts of the transmission are run in oil. An extension of the primary shaft backwards, provided with a jaw clutch, carries at the rear end a bevel gear meshing with another bevel gear on the belt pulley shaft. This set of bevel gears gives a reduction of speed in the ratio of 22/17.

Belt Pulley at Rear

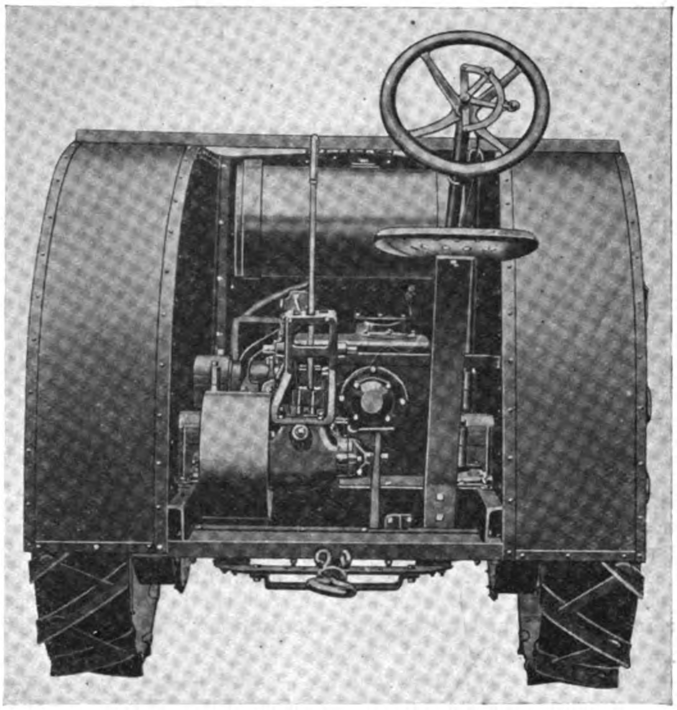
The belt pulley, which is located at the rear on the left-hand side, is 13 in. in diameter with 7 in. face. With the gearing specified, a belt speed of 3067 ft. per min. is obtained, at normal engine speed. The radial load on the pulley shaft is taken on a Hyatt bearing and the thrust load on a Timken. There is a safety bolt at each end of the belt pulley shaft. Control of the change gears is effected selectively by means of a lever working on an H-quadrant. The jackshaft of differential gear housing is built in one with transmission housing. The final drive is by bull gears of the spur type, which run in a bath of oil. The joint in the housing is only 3 in. from the axle, and 1½ gal. of oil is poured into each housing. This supply is said to be sufficient for a year.

The frame of the Velie tractor is built up of 5-in. steel channels weighing 9 lb. per ft. These frame members are bent so that they come below the rear axle. Everything on the frame is riveted and 7-in. gussets are used so as to insure the greatest possible rigidity. The rear axle is made of 2½-in. round stock, heat-treated and ground. Hyatt roller bearings are fitted in the rear wheels, there being two bearings at each end of the axle, each bearing 4 in. long. There is no single solid axle extending from wheel to wheel, but instead two short axles are used, each pressed into a cast axle horn which is bolted to the transmission. These horns are clamped between the axle brackets and their caps. The frame comes to a point at the front, and has a pivot support below the front axle, the center of the support being only 10½ in. from the ground.



The Velie tractor engine, carbureter side

The front axle is made of strip steel, and is riveted to cast steel axle ends. Drop forged steering knuckles are used, and are fitted with Timken roller bearings on the axle stub. The knuckles are of the Lemoine type, and steering is effected by means of a hand wheel and a worm and nut steering mechanism. The steering lock is such that the tractor can be turned around in an 18 ft. diameter circle, figured to the center of the machine. Two and one half turns of the steering hand wheel are required to bring the front wheels from hard over one way to hard over the other way. A reduction of 12:1 is obtained by means of the screw and nut mechanism. The steering hand wheel is provided with a wood rim and the steering mechanism is really a standard truck steering gear. Center control is used, and the spark and throttle levers are mounted on the steering wheel.



Rear view of tractor

Built-Up Wheels

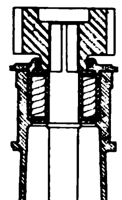
Both sets of wheels are of the built up type. The front wheels are 32 in. in diameter by 5½ in. width of tire, the tires being of the flanged type, and the spokes of round section. The rear wheels, which are 52 in. in diameter by 10 in. width of face, also have round spokes and flanged tires, the flanges being 1¼ in. wide. At the rear of the tractor there is a frame extension which carries a wood platform on which the driver can rest his feet.

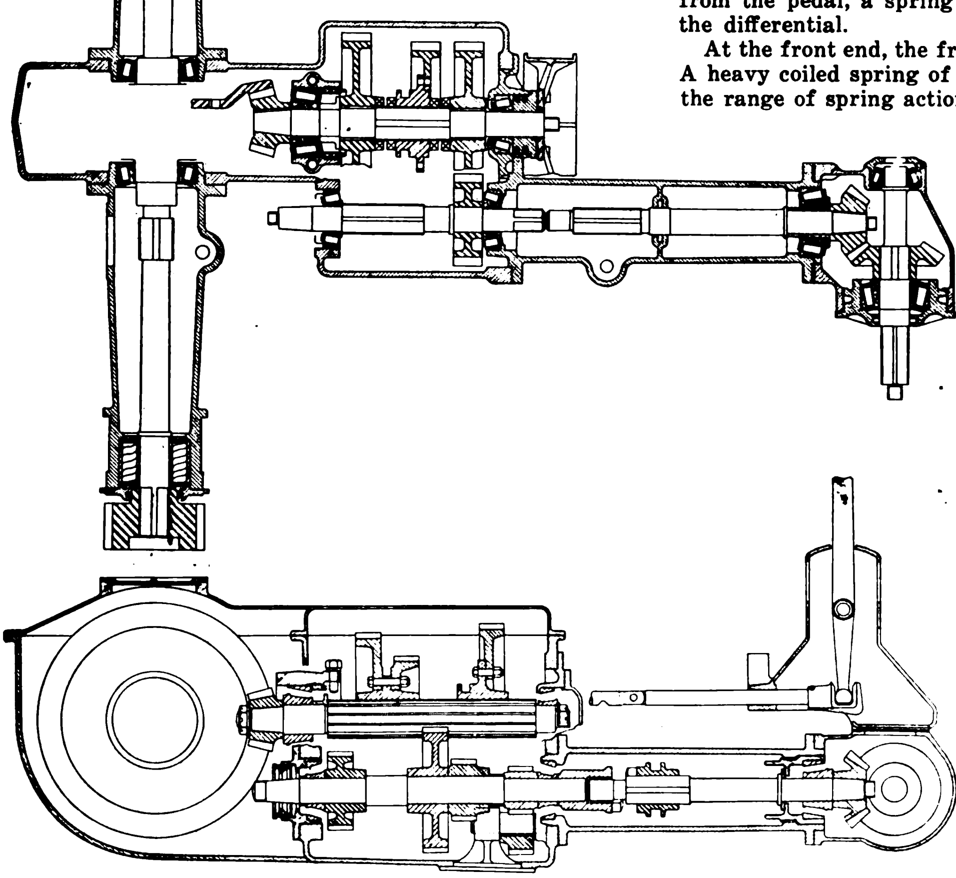
The drawbar attaches to a cross member of the frame. A bracket is riveted to the center of this crossbar, and from it run brace rods to the side members of the frame at points where the bull pinion bearings are located.

There is a spring cushion in the drawbar, and the latter has 18 in. lateral adjustment on a crossbar riveted to rear extensions of the frame. The hitch is 16½ to 17 in. from the ground, which is a convenient height for hitching such implements as binders, disc harrows, etc.

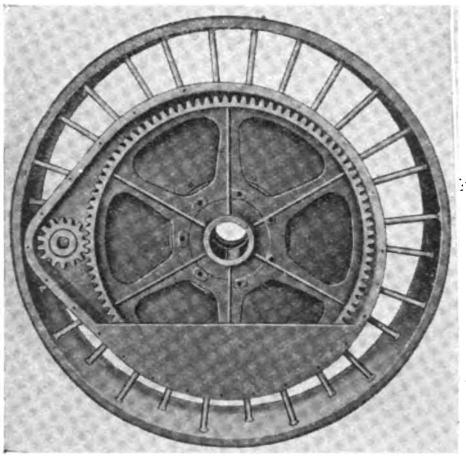
The Velie tractor has a wheelbase of 91 in. Its extreme width is 66 in. and the extreme length 138 in. An implement type of seat is used, and is supported by a spring secured to a cross member of the frame. Mud guards of No. 18 sheet metal, with an angle iron frame, are fitted over the rear wheels. These extend only to the center of the wheel forward, but down to the level of the platform at the rear. A feature of the Velie tractor is a differential lock, which can be engaged by means of a pedal convenient to the driver when in the seat. This lock is in the form of a jaw clutch, which locks one of the differential shafts to the differential housing, thus making the differential gear inoperative. When the operator withdraws his foot from the pedal, a spring withdraws the clutch, thus freeing the differential.

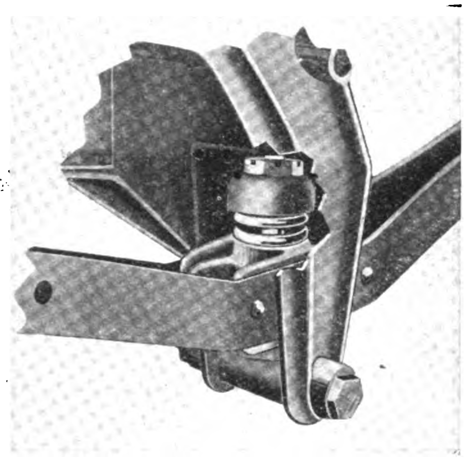
At the front end, the frame is spring supported on the axle. A heavy coiled spring of only a few turns is used and, while the range of spring action is small, it suffices to relieve those short period shocks which are so harmful to tractor mechanism. The front axle is braced to the tractor frame by two radius rods, which extend substantially parallel with the frame side members. The rear end of these brace rods is pivoted to brackets riveted to the frame, while the forward end extends through holes in the front axle, and is surrounded by coiled springs on both sides of the axle which act to relieve severe shocks on the brace rods. A mud pan of No. 16 gage sheet metal is located under the engine, and is designed chiefly to protect the engine from trash. The engine is set 2 in. to one side of the frame center. There is a permanent sheet metal hood over the engine, but the sides of the engine space are covered with heavy duck. Snap fasteners are used to fasten the duck at the bottom to the tractor frame, and a 5/16 in. steel rod is secured to the duck about half way up so as to prevent it from blowing against the engine. These duck curtains roll up and fasten by straps to





Two sectional views of the transmission





Left—Rear wheel, with bull gear and pinion and case for same, showing provision for keeping oil in

Right—Spring support of forward end of frame and pivot mounting of front axle

the hood. The water and gasoline tanks are located under the hood, with their filler openings projected above it, thus making filling of these tanks an easy matter.

All of the control devices are conveniently located at the rear. The gear shift lever also controls the belt clutch, there being an extra slot in the gear quadrant into which the lever is moved when it is desired to do belt work. This makes it absolutely certain that all of the gears are out of mesh when the tractor is used for doing belt work. All control levers are of neat and handy form

The price of the Velie tractor, completely equipped, including a set of Loxon lugs, is $1865.

Hints on Storing Timber to Prevent Decay

MANY serious losses from decay in wooden structures are possibly due to the fact that the timbers used were infected with wood-destroying fungi while in storage. These losses can be greatly reduced by keeping lumber storage yards in a sanitary condition. Some hints as to how to do this, issued by the Forest Products Laboratory of the U. S. Forest Service, Madison, Wis., are given below:

Strong efforts should be made to store the product on well-drained ground, removed from the possible dangers of floods, high tides and standing water.

All rotting débris scattered about yards should be collected and burned, no matter whether it be decayed foundation and tramway timbers or stored lumber which has become infected. In the case of yards already filled in to considerable depths with sawdust and other woody débris the situation can be improved by a heavy surfacing with soil, slag, or similar material. Weeds should be cut away from the piles to allow good ventilation.

More attention should be given to the foundations of lumber piles in order to insure freedom from decay and better ventilation beneath the stacks. Solid foundations should never be used. In humid regions the stock should not be piled less than 18 to 24 in. from the ground. Wood blocking used in direct contact with wet ground should be protected by the application of creosote or other antiseptic oils, or else replaced by concrete, brick or other durable materials. Treated skid timbers would also be highly advantageous.

Foundations should be built so that the piles will slope approximately 1 inch to every foot of length.

In most regions lumber should not be close piled in the open, but should be "stuck" with crossers at least 1 in. thick. Lateral spacing is also very desirable. Roofing or cover boards on piles should not be neglected, and should extend over for several inches in front and back.

Instead of throwing the "stickers" about on the ground to become infected with decay, they should be handled carefully and when not in use piled on sound foundations and kept as dry as possible. If pine, saturated with resin, or the heartwood of such durable species as white oak or red gum, be employed, the danger of possible infection will be greatly decreased.

In storage sheds the necessity for piling higher from the ground is very apparent in many cases. The same remedies apply here as for pile foundations in the open. The sheds should be tightly roofed and the siding should not be run down below the bottom of the foundation sills. Free air circulation should be allowed from all sides beneath the inclosure. Only thoroughly dry stock should be stored in close piles under cover.

Should fungous outbreaks occur in storage sheds not constructed to meet sanitary needs, the infected foundation timbers should all be torn out and replaced with wood soaked in an antiseptic solution or by concrete or brick. In all cases the new foundations should be so constructed as to keep the lumber well off the ground, and the soil and timber immediately adjoining the infected area should be sprayed or painted with an antiseptic solution of a water-soluble salt, like sodium fluorid, mercuric chlorid, zinc chlorid or copper sulphate.

A more detailed discussion of methods of handling lumber to prevent decay is to be found in Department of Agriculture Bulletin No. 510, "Timber Storage Conditions in the Eastern and Southern States with Special Reference to Decay Problems," obtainable from the Superintendent of Documents, Government Printing Office, Washington, D. C.; price 20 cents.

Theory of Action of Lead Cell

CH. FERY read a paper on the theory of the lead cell some time ago before the Société Française de Physique. It is argued that the usual assumption that the material of the negative plate passes through the form $PbSO_4$ during the discharge is a fallacy. This view is supported by a consideration of the change of weight of the negative plate during discharge, and also by the darkening of rolor of the plate, which would not be expected with the formation of white lead sulphate. It is more likely that Pb_2SO_4 is formed. This theory is supported by certain chemical reactions and changes of weight that were noted in experimental plates.

Carburetion Temperature of Oil Mixtures—Correction

N the article on the "Carburetion Temperature of Oil Mixtures" in the issue of AUTOMOTIVE INDUSTRIES for Feb. 27, there occurred a couple of typographical errors which should be corrected. In the second formula on page 491, the numerator ought to read $.01 \times 6.5 \times 760$ instead of $+ 760$ as printed. In the third formula on the same page the denominator should read 14×50, not $14 + 50$. In the last column on page 491, $746 = 460 = 286$ deg. Fahr. should be $746 — 460$.

Lack of Care in Promotion Retards Conference-Plan Development

Matters of Interest to the Worker Must Be Told in His Language—Legal Verbiage Unnecessary and Adds to Difficulties—Campaign of Education Required

By Harry Tipper

THE adoption of conference systems, the representative shop committees, and of joint government of working conditions by management and labor together is attracting a great deal of pubiic attention and is being announced by more individual plants every day. In some cases the systems have not appealed to the worker as thoroughly as they should and in some cases the manufacturers have been disappointed by the results where they have only been working for a few months.

It is evident from investigations which we have made of the matter that three cardinal points have been lost sight of in the preparation of some of these plans. Perhaps this is due to the lack of appreciation on the part of the manufacturers as to the worker's point of view. There is a very deep-seated suspicion on the part of the worker in respect of the motive which is behind all voluntary suggestions by the manufacturer. This suspicion arises out of past history, which has, in too many cases, provided a justification for it, and out of the lack of understanding and the consequent partial viewpoint which the worker has. The important thing is not the reason for the suspicion, however, but the fact of its existence and its strength.

Worker Must Be Educated to Appreciate Plan

In the promotion of all plans looking toward the establishment of the shop committee, or conference system, which will provide the worker with some share in the management of his own affairs, it is necessary to take this suspicion into account and clear it away before the plan can become operative in any real measure. All the arrangements which are made in advance of the submission of the plan to the workers should have in mind this necessity for the education of the worker to the reasons behind the plan and the opportunities presented by the plan.

In some of the details which have come to hand, concerning the action of individual manufacturers who have adopted this system, the carrying out of the plan and the provisions for its promotion among the workers indicate that the legal department of the company has controlled its preliminary operation too largely and the commercial, sales and advertising departments have not been consulted sufficiently in regard to the method of bringing it about. The attitude of the manufacturer who said: "It is true that we have made no attempt to promote this among the workers, feeling that a plan which offered such benefits and opportunities to the worker would, of course, be received with enthusiasm," does not offer any substantial hope that the conference system will work itself out in such a plan without considerable difficulty, before the workers' and employers' representatives come to any common ground of understanding. It is particularly unfortunate that a measure of this kind, which is intended to bring about a more democratic arrangement in the government of the worker's condition and give him a voice in the affairs, should be promoted in such a way that it does not bring with it a realization that its inception is due to a keener understanding of the demands of industrial progress and a more intimate knowledge of the worker's necessities and aspirations.

The terms of the conference plan, in a number of these cases, are characteristic of the methods of legal departments and the language of a lawyer. It is undoubtedly wise that the legal department of a large company should have a good deal to do with the articles constituting the conference plan, but the lawyer is not a close student of human affairs in business as a rule. His method of approach to a question does not lead to that simplicity and clarity which is absolutely necessary in a case of this kind if the value of the method is not to be befogged by the verbiage that surrounds its constitution.

In the manufacturing business the men who have charge of the sales and advertising work are better equipped to arrange an idea so that it will convey the right impression to the people who are to receive it. Their business every day necessitates the use of this knowledge and the cultivation of a considerable amount of it.

Where a conference plan is to be adopted, or where any organization changes are to be made in the expectation that they will offer a basis for the solution of the labor difficulties, the adoption of such a plan is of sufficient importance to justify the employment of the best brains in the concern for each particular part of the work, and no part of the preparatory work can be slighted without increasing the difficulties of operating the plan and materially lengthening the time required to make it successful.

Plan Must Be Adapted to Particular Case

In the case of one plan with which we have been in touch, the general counsel and the executives of the company spent not less than nine months investigating the merits of this or that plan and making their decisions upon the modifications necessary for that particular manufacturer. These provisions were drawn up, then the plan was presented to the workers by means of a notice and a dry booklet merely containing the proposed provisions. The whole presentation of the plan to the workers occupied three weeks and hinged upon the character of the notice and the booklet. Yet it is evident from the character of the booklet and the notice that no man who was accustomed to the work of impressing a body of men with the importance and value of a new idea had anything to do with the handling of these two matters. In fact, the adopting of this system by the workers in this particular organization, in the face of the methods which were employed to promote it, simply indicates the value

of a plan which can succeed in spite of such a presentation.

The mixture of races which obtains in many plants has not been taken into consideration sufficiently in most of the cases where this plan has been presented to the worker. It is sufficiently difficult for the average worker to understand, without an educational process, the benefits which he is to secure from a plan of this kind where he is conversant with the English language, the political habits and the ideals of the American people. It is sufficiently difficult to remove the suspicion which attaches to his mind where this background is provided.

In most plants, however, the problem is complicated by the fact that the labor is largely foreign, frequently including as many as twenty different races, few of whom have any knowledge of democratic institutions, most of whom have been brought up in the tradition of feudal systems, whose knowledge of English is frequently very limited and who have no background of traditional understanding of the American habits of mind and general political arrangement. Yet it is expected that these mixed races will, in the course of two or three weeks, with a single notice, a few brief explanations and a complicated document of provisions, understand what they are to vote about and the benefits which they are about to receive by virtue of such voting. Under these circumstances it is not amazing that in some cases the voters have not approved of the plan. The only amazing thing is that the workers have in most cases approved of the plans and that the rejections have been so few and far between.

Whether the plan has been adopted or not, under these conditions the lack of care and attention in the promotion of the plan, particularly to the mixed races that are to be found in most of the large manufacturing establishments, will, without any question, militate against the progress of the plan, increasing the difficulty of getting it into thorough working order, and lengthen the time which is necessary before it will be of definite value.

The third item which has not been sufficiently considered in the presentation of this plan is the necessity for simplicity in the provisions of the plan and the danger of including in the constitution too many operating definitions and limitations.

Temporary Character of All Operating Plans

It is necessary to emphasize again, as we have emphasized before, the temporary character of all operating plans in the building of human organization. The operating necessities are constantly changing and the value of any committee, or any established body, within an industrial organization grows as the body gets to work and makes it valuable for decision upon or discussion of matters which were not originally thought of. This is true of all legislative organizations and all committees which deal with policy and the methods of putting that policy into operation. Under these circumstances the provisions of the plan as it is presented for adoption should be as simple and elastic as possible. The committee, or conference, should be started at work upon the least important and most immediate of operating necessities, but neither its authority nor its work should be so limited by the original provisions that it cannot be extended in its operations to cover matters for which it proves to be the most effective body as it grows and develops.

There is a second danger involved in complicated provisions, and that is the danger of a constant discussion as to the interpretation of those operating provisions which lead away from the main issues and prevent the organization from proceeding in an orderly way toward the development of the proper harmony in the main requirements.

We have received in the course of the last few months booklets containing the plans established by approximately twenty-five organizations, and in 70 per cent of these cases, where these booklets have been passed out for comment in our own organization, they have elicited requests for further information in order to elucidate several of the provisions and statements of procedure. In four or five of these booklets the things for which the employee can be discharged without redress, the things to which the company reserves its rights and similar matters make up the first few pages of the booklet, while the plan which is intended to confer the various benefits upon the employees is left for the last pages of the booklet and presented without any real explanation.

The method of promoting and presenting the conference plans to the employees of the industrial organization is just as important as the character of the plan itself, and it will advantage the manufacturer greatly to see that those executives in his establishment who are most capable of understanding methods of promotion be called in upon the promoting and presentation, so that the plan is thoroughly understood before its adoption and the proper amount of enthusiasm created in respect to it. The value of the plan will be enhanced very greatly by such measures and the difficulties correspondingly reduced.

The Strength of Commercial Liquid Glues

MOST of the commercial liquid glues are manufactured from the skins, heads and swimming bladders of fish. Others are made by special treatment of the glue extracted from the hides, skins and bones of cattle; some for special uses are prepared from starch, from various natural gums or from casein.

At the Forest Products Laboratory tests were made by B. A. P. inspectors on a number of these liquid glues, who found that they differ very widely in strength. Some of them are so weak as to be entirely unsuitable for woodworking purposes, while others compare favorably in strength with the "hot" glues. The glues tested varied from one which exerted a binding force of less than 50 lb. per sq. in. to one with an adhesive strength 60 times as great, or more than 3000 lb. per sq. in.

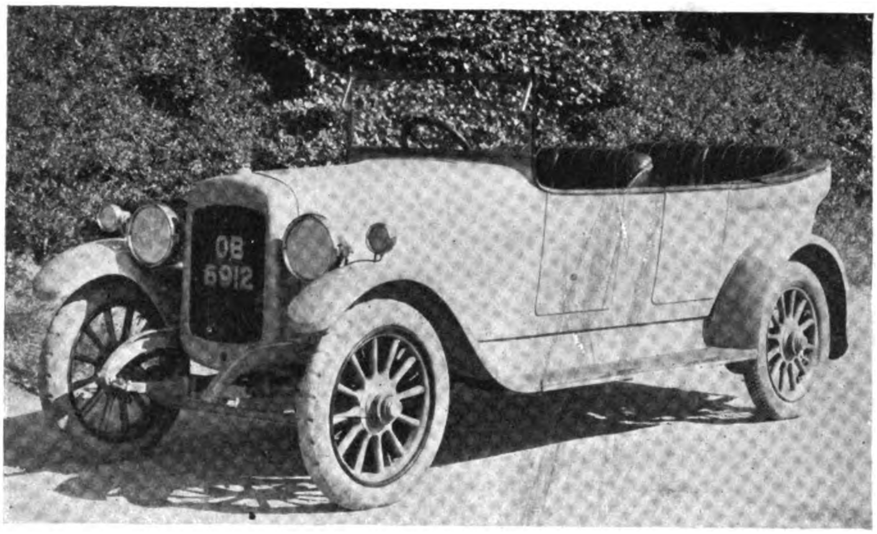
Liquid glues may be tested by gluing together pairs of specially selected hard maple blocks, placing them in a testing machine and measuring the force required to shear them apart. About 300 specimens, representing 26 different glues, have been tested in this way at the laboratory. According to the data thus obtained, a high-grade liquid glue should have an average shearing strength of not less than 1700 or 1800 lb. per sq. in.

In addition to uniform high adhesive strength, it is evident that certain other characteristics are desirable in a liquid glue. When spread upon wood surfaces, it should "set" and dry rapidly. In its container, it should remain fluid and workable at all ordinary temperatures. It should be elastic and shock-resistant. It should not be unusually susceptible to the action of high temperatures, high humidity, molds and bacteria.

The study gave evidence that the strength of liquid glue, like that of "hot" glue, depends largely upon its "body" or thickness, or, strictly speaking, upon its viscosity. Of 11 liquid glues examined, the thickest or most viscous glues showed the greatest adhesive strength.

NO less than ten national aircraft factories were erected or purchased by the British Ministry of Munitions. All of these were completely finished, and engaged in production for some months prior to the armistice. The approximate cost of these establishments was $11,300,000.

A New British Quantity-Production Car



The Austin, Rated at 20 Hp., but Developing 45 Hp. on the Brake — Body Designed with Receptacle for Top—To Be Offered in Open Touring, Coupe and Landaulet Models

Austin open touring car

EUROPEAN manufacturers of automobiles have taken a leaf out of the book of their American confrères and are adopting a number of practices that, while popular here in the past, have been practically unknown abroad. One of these is the production of a single model in the greatest possible numbers consistent with manufacturing facilities and the visible market. Another is the production of complete cars instead of bare chassis. Both these practices are intended to reduce the cost of the machine to the consumer, and the ultimate object is to create a wider market.

One of the first British post-war models to be announced, and which is to be manufactured along these lines, is the Austin "twenty." This had been completed before the signing of the armistice and was shown to members of the delegation of American business paper repre entat ves which visited England and France in November and December of last year. In this connection it may be well to recall that the Austin plant grew enormously during the war and during its later stages employed around 25,000 persons. Consequently, if the resources of this enormous plant are to be devoted to turning out one passenger car model the annual output should be very high. It is somewhat surprising that the price contemplated is in the ne'ghborhood of $2,000 for the standard touring model, which is considerably beyond that asked for American cars with much larger engines.

There are four L-head cylinders cast in block, with detachable head, and the crankshaft is supported in five bear'ngs. The camshaft is driven by a silent chain of ample dimensions. The crankcase has large inspection doors.

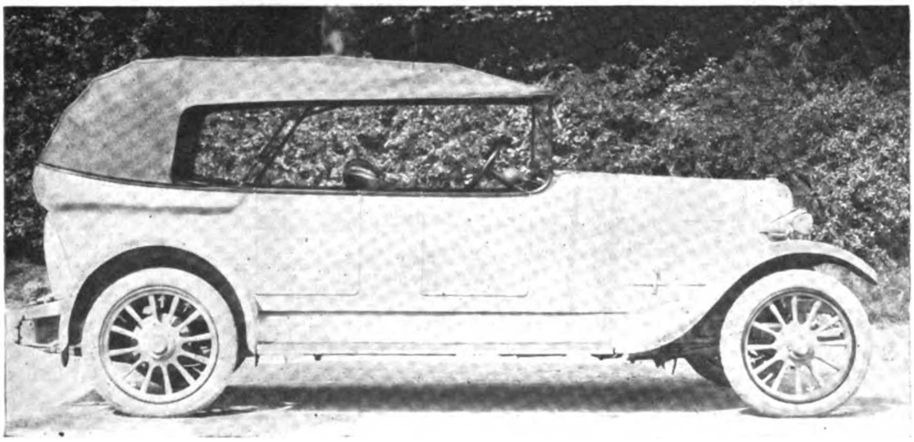
An automatic carbureter is fitted. The inlet p'pe is combined with the exhaust manifold, so that ample heating may be obtained. An extra air valve is fitted and is controlled by a lever on the steering wheel. Ignition is by coil and battery with a high-tension distributer. Lubrication is by means of a gear pump which forces oil through the hollow crankshaft to all bearings. A strainer is placed in the bottom of the crankcase and by this means all oil is strained before being circulated. A strainer is also fitted to the filler. Cooling is effected by the thermo-syphon system. A honeycomb radiator of ample size is provided and assisted by a high-speed fan.

Some idea of the general characteristics of the car can be gleaned from the following specifications:

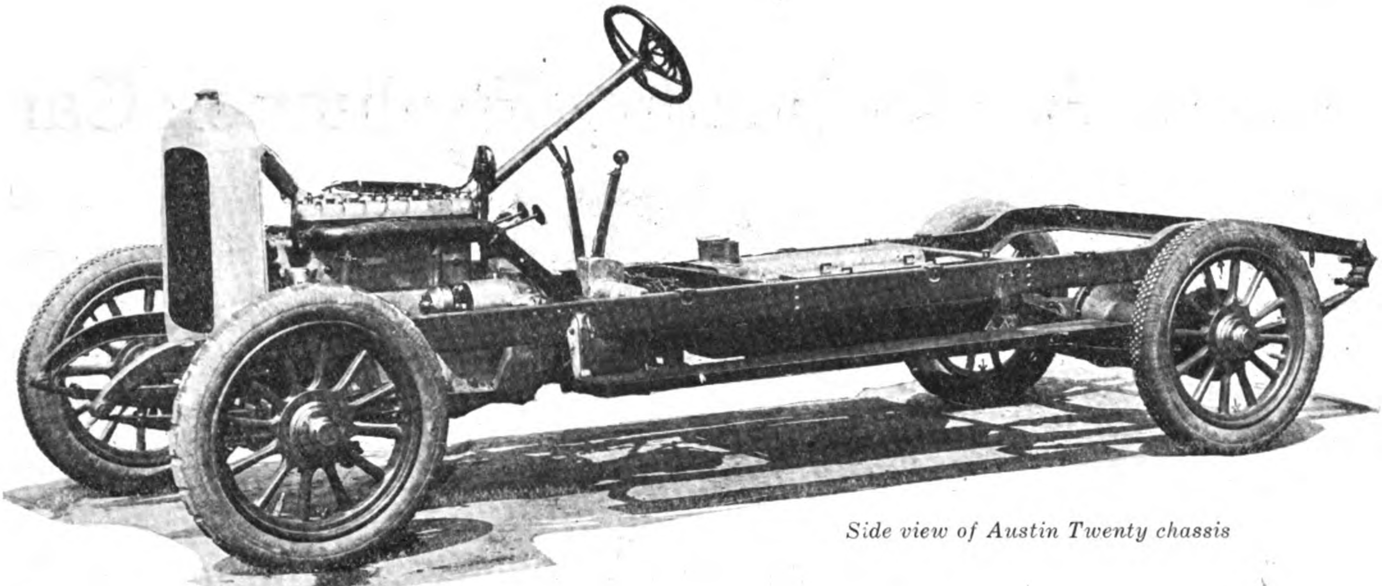
Wheelbase	10 ft., 9 in.
Tread	4 ft., 8 in.
Width overall	5 ft., 2½ in.
Length overall	14 ft., 11 in.
Body space	8 ft., 7½ in.
Distance from rear of dashboard to center of rear axle	7 ft., 11 in.
Tires, standard model	32 x 4¾ in.
Colonial model	36 x 4 in.
Ground clearance, standard model	9 in.
Colonial model	11 in.
Approximate weight of chassis	2000 lb.
Bore and stroke	3¾ x 5 in.
R. A. C. rating	22.4 hp.
B.-hp. of engine at 2000 r.p.m.	45.

Fuel is fed by gravity through an Autovac secondary tank. The main fuel supply is carried in a 15-gal. tank supported on substantial brackets attached to the cross-members in the center of the frame. A fuel lever indicator is supplied, and an outlet pipe fitted at the bottom. Ample filling arrangements and a large strainer are provided in an accessible position under the front seat. A combined electric self-starter and lighting equipment is provided, and there is also a detachable starting handle for use in case of emergency.

A single-plate pattern clutch with asbestos friction facing is fitted. The gearbox gives four speeds forward and



Austin touring car with top up



Side view of Austin Twenty chassis

one reverse, the shafts being carried on ball bearings. The speedometer is gear-driven from the change speedbox. The change speed is operated by a lever through a gate, which, with the brake lever, is fixed in a central position. The engine and gearbox form one unit with three-point suspension on the frame.

The rear axle is of the three-quarter floating type, the axle housing carrying the rear wheels on ball bearings, thus relieving the shafts of the chassis weight. The main driving gears are of the helical bevel type.

The I-section front axle, knuckle and knuckle arms are forged of high-grade steel, carefully tempered so as to resist fatigue. The front wheels run on roller bearings with ball thrust. The steering is of the worm-and-sector type, with a stationary outer column supported from the cowl, and is fitted with a 17-in. wheel, with the throttle, ignition, and extra air levers on a stationary quadrant.

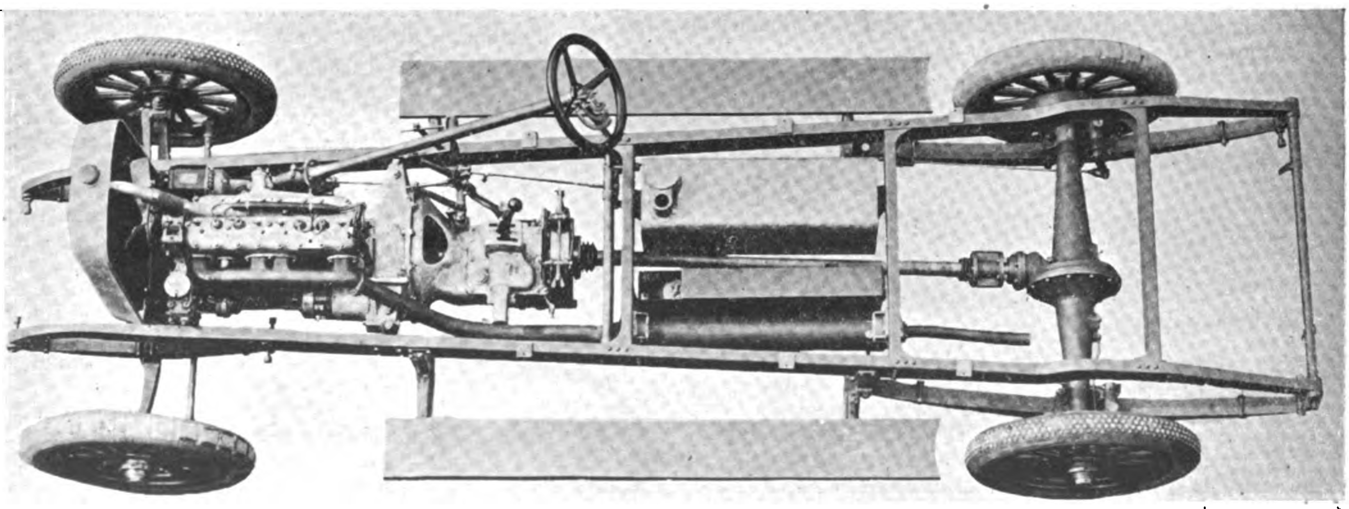
The chassis springs are semi-elliptic, the rear being of the underslung type 60 in. long, while the front are 36 in. long. Special provision is made to prevent rust between the leaves.

Metal-to-metal internal expanding brakes act on drums on the rear wheels and contracting shoes faced with asbestos fabric close upon a drum mounted on the third motion shaft at the rear of the gearbox. The car is fitted with Austin detachable artillery wheels as standard. One spare wheel with studded tire is also provided. Three separate types of body are to be mounted on the chassis—the standard model open touring car with top, a four-seated coupé, and a landaulet.

The standard touring model is an elegant piece of work. The top, when not down, is tucked away into a neat, well-drained receptacle. The front seat is arranged to slide backward or forward and is adjustable to any angle. There is an all-metal framed windshield with both top and bottom halves deflecting. The electric lighting outfit includes two powerful headlamps and side and tail lamps. A specially arranged tire carrier with metal cover is fitted at the rear and can accommodate two spare wheels. All doors are fitted with interior locks and concealed hinges. The general finish is in nickel and the body work is painted in one of three standard colors, gray, dark green or blue, with upholstery to match.

The coupé is a roomy four-seated car with streamline body accommodating two passengers at the rear and two at the front, the rear seats being fitted with arm rests at each side. The top is of black leather and is capable of being raised with automatic raising and lowering gear, while the door windows are in two parts arranged to slide horizontally, the frames thus falling inside the doors when not in use. A window is also provided at the back of the top. The lighting arrangements and general equipment resemble those of the touring car.

Features of the landaulet model include a semi-domed roof with fixed sloping canopy, automatic folding head with cant rail and concealed head joints. All doors are fitted with concealed hinges, large lever locks, and silent dovetails. Easily raised frameless and noiseless windows are fitted to doors and quarters. A specially arranged tire carrier with metal cover is fitted at the rear, and can accommodate two spare wheels. The tool equipment includes a complete set for average running, carried at the rear of the car, in a new type toolbox, and some special tools for use in the garage.



Plan of chassis. Note location of fuel tank (vacuum feed) and storage battery

F-5-L Navy Flying Boat

Details of Flying Controls and Method of Hook-Up—Weight and Percentage of Weight of Every Component

By S. T. Williams
Assistant Chief Engineer, Naval Aircraft Factory, Philadelphia

PART IV

IN the previous three articles describing this boat, the various outstanding features of the hull, wing panels, engine mounting and gasoline systems were outlined. The boat is a twin-engined tractor biplane equipped with Liberty engines. It has a wing span of 103 ft., with wings 8 ft. wide, and a boat hull 45 ft. long and 10 ft. wide. The total flying weight is 7 tons and the cruising radius is 10½ hours as a fighter and 8½ hours as a bomber.

The outstanding features of the flying controls are the laminated-yoke dual elevator and aileron control mounting, and the adjustable rudder bar installation.

The yoke itself is built up of ⅛-in. laminations of ash, glued and riveted together, making a strong and light construction. Each end is extended to form the elevator throw, and the aileron control wheels are mounted on brackets at the top.

These wheels are connected by an endless chain, from the middle of the lower part of which are taken the aileron control wires. The cross tube is integral with the yoke, and the whole swings on bearings at the hull sides.

In addition to lightness of construction, rigidity, and simplicity of wiring, this control affords a maximum amount of room for passing from the front to the rear cockpit, and does not interfere with the legs of the pilots as does a post type control.

Originally, adjustment of the distance between the pilot and the rudder bars was effected by shift-

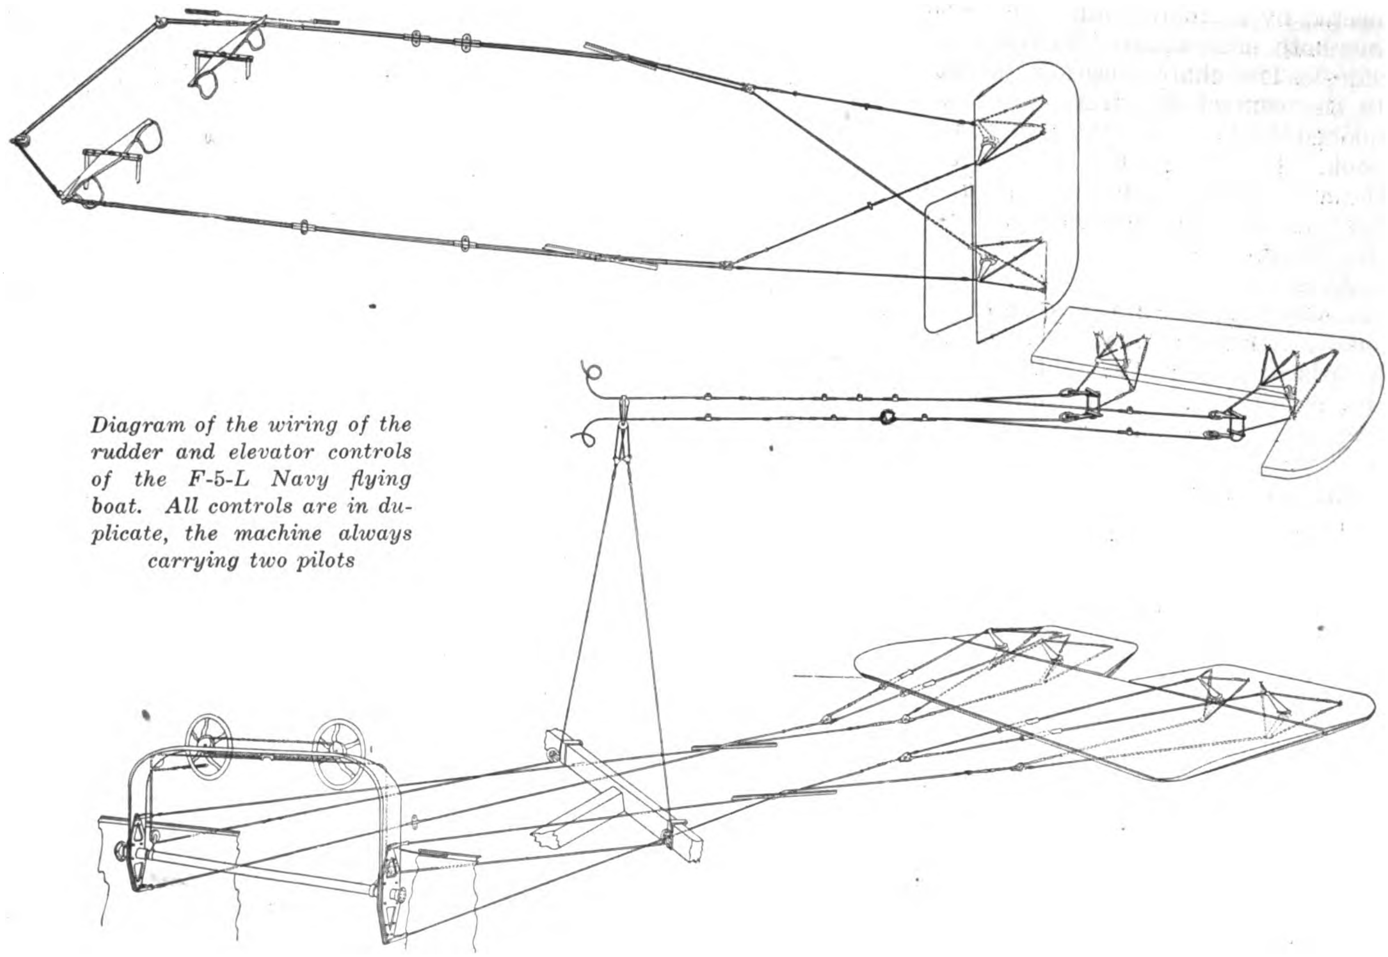


Diagram of the wiring of the rudder and elevator controls of the F-5-L Navy flying boat. All controls are in duplicate, the machine always carrying two pilots

ing the seat. But this also brought the control wheel closer, and the installation was complicated. Adjustment on this plane is effected by shifting the rudder bar bodily fore and aft the required amount.

The rudder bar is carried between two straps that are supported on a tubular framework in front of the pilots. These straps have a series of holes, and the rudder bar may be set to swing on a pin passed through any one of these. A similar adjustment permits the outer end of the bar to be set properly in connection with the rudder cable. As these pins are set in place by a small brass cotter, any desired setting can be made quickly.

Under severe flying conditions, or in the case of tail or nose heaviness, it is sometimes necessary for the pilot to exert a continuous pressure on the controls. On the elevator or rudder controls, this continuous pressure may be applied at will, in any desired amount through rubber cords called "bungies."

The complete bungy is simply two pieces of rubber cable, connected by a small chain, and having both ends secured to the hull sides. The chain passes adjacent to the control it governs, and is hooked to it at will with a snap hook. The pressure is applied to the control by extending the rubber cable before the attachment of the chain.

All control cables are carried on brass ball-bearing sheaves, and the sheave housings are fitted with guards to prevent the cables from coming off. With the exception of the point where the aileron cables pass through the upper wing, all control cables are open to inspection.

Steaming Green Lumber

SATURATED steam as a means of alleviating the tendencies of green lumber to honey-comb in the kiln has for some time been successfully applied in the commercial drying of heavy vehicle stock. Under intelligent control, such treatment has meant the difference between success and failure in many kiln runs. It has frequently afforded the means of overcoming discrepancies in operation or misjudgments as to the ability of stock to withstand rigid drying conditions.

So far, however, the steaming treatment has been confined to straight stock. The contention has always been that bent stock, such as rims, should not be steamed after removal from the form, experience indicating that stock so treated would tend to straighten out to its original shape. The kiln drying of heavy bent rims has been carried on, therefore, without resorting to steaming to remove casehardening and other defects of drying.

Recent experiments conducted under the direction of the Forest Products Laboratory have shown that judicious steaming of heavy bent vehicle stock results in a considerably improved product, and that the operation can be accomplished without serious effect upon the curvature. Careful judgment is necessary, however, as it is a very easy matter to ruin the entire charge by too severe treatment. Contrary to the common impression, this steaming has been done at high temperatures (150 to 180 deg. Fahr.) and for short periods (½ to 3 hours), the temperature and time varying according to the requirements

Copper Alloys

A PAPER on the above subject by Dr. W. Rosenhain was read at the annual general meeting of the Institute of Metals in London on March 25. It describes the method of preparation of a number of copper alloys and gives the results of tensile and hardness tests carried out on them. The alloys were intended to meet very stringent requirements involving extensive cold-working, so that high tensile strength with great ductility was aimed at.

The alloys dealt with fall into two main classes. The first class consists of alloys of copper with aluminum, with manganese, and with both aluminum and manganese. Difficulties were experienced in casting these alloys into slabs, and special methods of casting were adopted. A process sometimes known as "pressure casting," which has been developed and patented by F. Tomlinson, was eventually adapted for use with these alloys and proved very successful. In this method the liquid metal is forced, by means of externally applied air pressure, through a feeder tube dipping into the molten metal nearly to the bottom of the crucible and communicating with the bottom of the mold. Alloys cast by this method were subsequently rolled into strips. The results of tensile tests show that a very high degree of ductility can be obtained, together with considerable tensile strength, by the use of aluminum, or aluminum plus manganese. For example, the alloy containing 7 per cent aluminum without manganese has a tensile strength of just under 80,000 lb. per sq. in., with an elongation of 17.5 per cent in the "as rolled" condition, while after annealing it still has a tensile strength of 55,000 lb. per sq. in. and the remarkable elongation of 71 per cent.

The second class consists of alloys containing no aluminum: these are mainly combinations of manganese and zinc, or nickel and zinc, with copper. They were cast successfully with the aid of borax as a flux and and were subsequently rolled into thin strips of excellent quality. Of this series the strongest alloy is that containing 3 per cent manganese and 10 per cent zinc, which, in the cold rolled condition, has a tensile strength of 94,000 lb. per sq. in., with an elongation of 3 per cent, and in the annealed condition a tensile strength of 46,000 lb. per sq. in., with 35 per cent elongation.

Suggested Touring Sedan

Single or Double Compartment, with Baggage Space and Rear Trunk—Straight-Effect Body Lines

By George J. Mercer

THE inside-drive sedan type is the most popular custom order body, and any builder will confirm the statement that more than half of all the orders for special bodies are of this class of design. For a while the body with the removable pillars, in which the side-window openings are all made into one, had a large following, but that has lessened each year for two seasons, and to-day the orders for this design are negligible.

Close-coupled, compact bodies are the rule now. The car owner is buying for himself rather than for his friends' convenience, and the snug, sensibly proportioned body does have a degree of style and smartness to it that the large buslike looking bodies never can have.

The design illustrated is for four passengers, including the driver, and has a division with a large glass that drops entirely down, so that it can be either a two or a one-compartment interior. For an emergency, an extra seat, close to the partition, and so that the one extra passenger can sit across the car, is quite within reason, as the proportions will permit of this.

This design is specially suitable for touring and vacation trips, as provision is made to carry luggage and wraps. The rail on the roof is only one bar high. It is intended to be used for carrying spare wraps, coats, robes, etc., inclosed in a rubber or tarpaulin bag, and is never intended that anything other than such articles should be put on top. There is room inside the body, forward of the feet, for such satchels and bags as will be needed, in addition to the trunk at the rear, which trunk is back of the tire, and in a measure is inaccessible; but it is the best place for it. As it will not be needed except when long stops are made, it can be lifted off and taken to the room of the hotel. Used in this way, it will have a real value, and will hold those additional necessities needed en route.

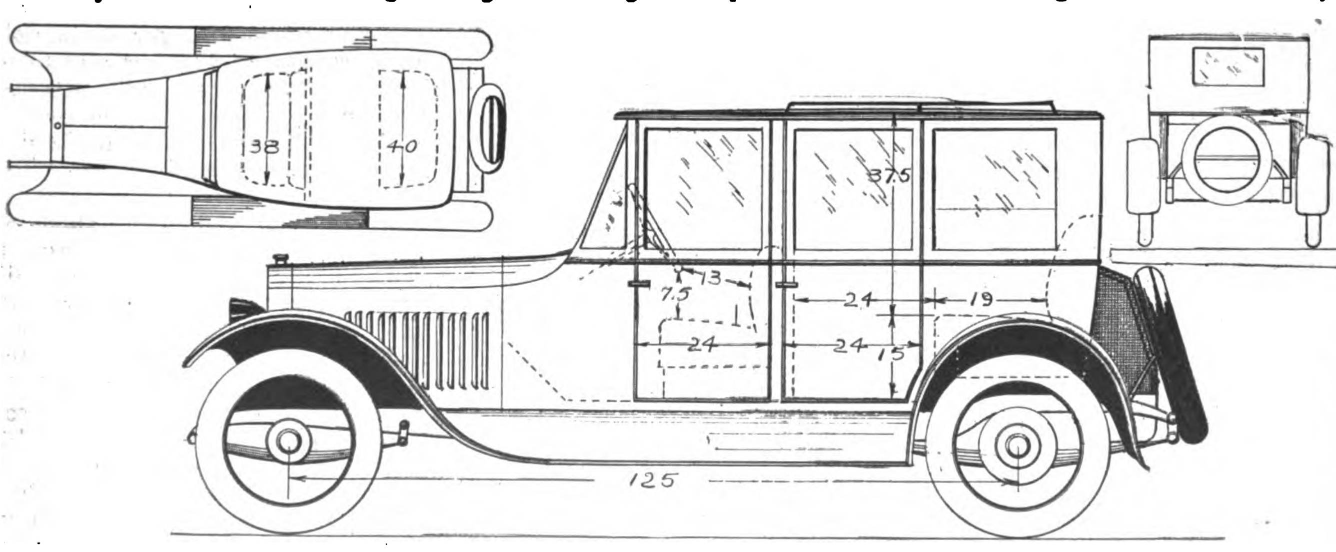
The object aimed at in this design is to get the straight effect throughout, and not only the horizontal but the perpendicular lines of the sides and back. These upright lines can never be actually straight. If so, the body would look too much like a box if there were not some curve or turnunder to relieve the flat look. The body must be narrower at the bottom than at the top to reduce weight and conform to the chassis width.

Another fact not so generally known, except to the trade, is that the surface of a body, when painted and varnished, always looks a trifle flatter than it actually is, and the varnished surface looks better when convex than when flat; hence the flat-sided and flat-backed body really has more turnunder sweep than is supposed.

The intention of the designer is to have the body straight, yet flat-looking, and that is one of the reasons that has helped to bring in the small bodies. A close-coupled narrow body can incorporate the requisite appearance qualities because of its size.

The design illustrated by side, back and top views is intended for a chassis of 125 in. wheel base, with 32 by 4½ tires. The angle of the front windshield post is 22 deg. from perpendicular, and this is made to blend well with the line of the engine hood, both on the top and at the line of the post.

The construction of this body is plain, the only moldings being around the doors, the middle horizontal, and the drip at the top. Both the horizontal moldings extend entirely around the back, thus permitting the joining of the upper and lower panels without welding. The roof is of laminated wood, and covered with cloth in the customary coachmaker's method. Metal roofs are being used quite extensively, but to use metal the roof should be more convex than this design, the reason being that metal requires to be strained in order to lay tight. When flat it will whip, although on this body the slats to protect the roof from damage where used as carrying



Touring Sedan body with four doors. Front windows operated by regulators. Rear side quarters have concealed lift straps

space would be a sufficient binder to keep any metal from giving trouble through moving. These slats are wood, put on with screws after the top surface has been well protected with paint. They simply keep the articles that may be carried on the top from defacing the protecting paint. The rail, three-eighths round, and supported by standards at the corners and in the middle of each space, is only high enough to secure the straps holding the baggage.

The trunk on the rear is of the customary design, but must be made to fit the job, and is intended to be lifted off when taking articles from it. The extra tire is released from its holder when the trunk is removed.

The outside line of the body is illustrated to good effect on the plan view. This effect is pleasing, and the aim is accomplished in having a smooth extended line from the radiator to the end of the body. The radius of the rear corner is less than usual. It is a tendency to have the rear corner of shorter radius than formerly; in fact, there are more square-cornered rears than since the early days of the automobile. Personally, I think that a square rear corner is not suitable for a body as large as this design. The radius may be only 1 in., and it will look well, but a square corner is suitable only for a small two-passenger job. It has a balance on a small body that is not needed on a larger body.

The illustration shows four doors, with windows operated by regulators, except the rear side quarters, which have concealed lift straps and the glass drops to the line indicated. The other windows all drop flush. The triangular one at the front and the back window are stationary.

The front windshield is two-piece, the upper one swinging outward and the lower part being stationary. There is a tendency at present to have the lower part of the glass swing inward to serve as a ventilator, but it stands to reason that this will surely let in the rain, and it can be arranged by having a ventilator on top of the cowl, which can be made watertight. The ventilator on the side of the cowl has been discontinued on account of the hot gases from the engine-hood louvres coming in.

The metal used on this body must be aluminum sheet for custom work, and the entire surface is so covered except the roof.

The essential dimensions for comparative tests with another body already built, to see if they are right for the person interested, are given on the several views. These dimensions are for the average person, and are intended for comfort and luxurious thick trimmings.

A sport type would be 2 or more inches lower, as the fancy of the owner dictated, and could be 2 in. narrower for the same class of customer. Sensible proportions, however, are best adapted to bring out harmonious lines, as this design illustrates.

The doors are hinged to open forward, and exposed coach hinges are used to save thickness in the pillars. Bar handles and locks on each right-side door should be specified. The windows are proof against opening from the outside, where regulators are used. The quarter windows must have a fastener to prevent opening from the outside.

The most popular color scheme has been Rolls-Royce blue and hair-line yellow striping, with silver-finish door handles and lamps. A radiator of silver finish would add beauty and harmony to the car.

Interior trimmings have been quite modest in design and color, and a gray with small black markings will go well with this color scheme.

Liberty Carbureter Gasoline Strainer

ON all the Liberty engines shipped after Nov. 10, 1918, a new form of carbureter gasoline strainer was used. There had been some difficulty experienced through dirt working into the carbureter jets, and disturbing the measured flow necessary for the best results. This occurred because there was no strainer in the gasoline system between the tank and the carbureter, and the gasoline being in contact with the rubber hose, rotted this after a time, causing particles of rubber to be carried along into the carbureter.

To avoid this difficulty a gasoline strainer was designed to filter the gasoline entering the float chamber and to make an easy mechanical break-down for removing the carbureter. This strainer incorporates a bucket screen. The gasoline entering from the top, filters through the screen, while the dirt is caught in the bottom of the bucket, which can easily be removed and emptied at intervals.

As a further protection against rubber particles, a brass hose liner or "olive" was inserted in the rubber hose. This strengthens the hose and acts as a spacer between the supply pipe and the strainer intake. The tapered ends of the olive fit into the beveled ends of the pipe and strainer, preventing the gasoline coming into direct contact with the rubber. The entire layout and method of assembly is shown in the sketch herewith.

To install the strainer assembly, it is only necessary to remove the gasoline connection from the carbureter bowl and screw the strainer in its place. The gas line attaches to the gasoline connection at the top of the strainer by means of the rubber hose containing the brass hose liner. Suitable clamps are supplied with the service set.

High Duty to Bar American Automobiles

DURING the past two years we have heard a great deal about the war after the war, which phrase was generally used to convey the meaning that after the cessation of military operations hostilities would be continued by means of trade boycotts, discriminatory tariffs and other suitable means, the inference being that the line-up of Powers would be the same as in the military struggle. But recent news reports from Paris suggest that in the automobile field at least the phrase may soon come to have an entirely different significance.

As duly recorded in last week's issue of AUTOMOTIVE INDUSTRIES, representatives of the automobile manufacturing industries of all the Allied countries held a convention in Paris recently at which post-war policies were discussed. Following the practice of another famous convention now sitting in Paris, the sessions were held in star chamber, and a properly expurgated official report was issued. It has leaked out, however, that the convention decided on a tariff duty on automobiles of 10 per cent between the different European countries and a duty of 45 per cent in Europe against American automobiles.

At first sight this appears alarming. Fortunately it is not the automobile industries of European countries which make the tariff laws of those countries. The only thing the Paris congress can do is to urge upon its members to recommend to their respective governments that certain steps be taken with respect to the taxation of automobile imports. Inasmuch as the automobile manufacturers are not disinterested and unbiased persons it is rather doubtful whether much heed will be paid to this advice by the legislatures.

It may be that the idea in holding the convention at Paris at this time was to exert some influence on the Peace Congress, as the latter is to consider post-war economic questions among others, but it is greatly to be doubted whether the Peace Congress will stop to consider such detail matters as automobile duties. If it deals with the subject of duties at all it will probably formulate some general rules which are applicable to all lines of merchandise alike.

It appears that the Paris Congress of Automobile Manufacturers is to continue the work of the former Association Internationale des Chambres Syndicales d'Automobile Reconnues. This was a rather loose organization with headquarters in Paris, the secretaryship being identical with that of the French Automobile Manufacturers' Association. The chief function of the association in the past was to assist in the dating of automobile shows so as to obviate interferences. At one time also a decision against participation in races was made. No really active organization ever existed, but on a few occasions representatives of the foreign automobile industries were called to Paris to discuss certain topics of mutual interest. As American manufacturers previous to the war rarely exhibited at European shows and took no part in European automobile races our N. A. C. C. nor its predecessor was ever a member of the International Association.

The action taken by the Paris congress reflects the fear of American competition. At the present time automobile imports are totally prohibited in both England and France, but it is realized that these prohibitions were war measures, and that although they are continued in force pending the reconversion of the home industries from a war to a peace basis they cannot be continued indefinitely. The doors must be opened again before long and the terms of admission to be offered to American machines is a point of great importance. Whatever the effect of the resolution may be on future tariff legislation, it should not be lost upon the great importing markets of South America, Africa and Australia. Manufacturers of the different Allied nations have practically gone on record that they consider themselves to be on a sufficiently even footing to enable all of them to agree to a reciprocity measure, but that the United States must not be admitted to the pact.

Quality in Inclosed Cars

SOME years ago closed bodies were fitted only to high-grade chassis, and the possession of a closed car was regarded as a sign of affluence. More recently, however, the manufacturers of low-priced cars have responded to the demand for closed vehicles suitable for all-year use and have brought out designs which are very attractive in appearance. There is considerable demand for these vehicles, which commend themselves especially to elderly people and to families in which there are persons not in the best of health. That these vehicles make a strong appeal was noticeable at last winter's show, where they were usually surrounded by interested visitors.

Unfortunately, the interior finish and fittings of the coupés and sedans offered are not always what might be anticipated from the attractive lines and the rather high price. These are defects which should be promptly remedied, if it is desired to build up a permanent trade in these models. It should be remembered that the owners of closed cars see much more of the interior than of the exterior of their vehicles, and any unsightliness or cheapness in the interior finish will soon offend them and cause them to become dissatisfied. Take, for instance, the matter of floor mats. These often have a cheap appearance when new and soon wear threadbare. Metalwork sometimes shows rough corners and badly finished surfaces, and the interior paint work is of a character that would not pass inspection in a first-class shop. It may well be that a purchaser who has been captivated by the attractive lines of the vehicle soon becomes disgusted with the shabby interior and develops a grudge against the manufacturer.

During the war many things were excusable, as most of the best mechanics were on Government work and good materials were hard to get, but now that the war is over and the restrictions are removed there should be a general improvement in the quality of construction, and especially in the interior finish and fittings of moderate-priced inclosed cars.

The Cyclonette

A FORM of light motor vehicle that has met with considerable success in Continental Europe but has never been introduced here is the cyclonette, which is in a way a cross between a motorcycle and a light car. It differs from a motorcycle in that one does not ride astride it, but it resembles a motorcycle in having a tubular frame, a light air-cooled engine, suspension wire wheels, etc. The machine would seem to fill a demand similar to our motorcycle with side car, over which it would appear to have certain advantages.

In the cyclonette the engine is mounted on the front fork, with which it turns in steering, and it drives directly to the single front wheel. Evidently the conditions are unusually favorable to effective air cooling. There are seats for two between the two rear wheels, which are located rather low, giving the vehicle a high degree of stability. There is no side draft as in a side car, and the driver is certainly seated more comfortably.

The weak point of the cyclonette appears to be that the proportion of the total weight that is supported by the driving wheel is rather small especially in climbing steep grades, so that it might be difficult to get traction if the road surface was at all slippery. For use in fairly level districts and possibly for taxicab service in cities a vehicle of the cyclonette type may have a future.

Air Code Should Be Criticised

THE formulation of a preliminary international air code at Paris should be given the attention of all who are interested in the future of aviation. The primary code is purposely intended for criticism and revision. It is given to the world so that it can be carefully considered and constructively criticised in order that an intelligent, comprehensive and complete international code can be finally arranged.

Consequently, it is to the professional pilot, individual airplane owner, aeronautical engineer, airplane engine builder, plane maker, manufacturer of dirigibles and producer of balloons that the interministerial commission addresses itself. And it is to the interest of each of these to examine the report carefully and offer suggestions. There is no question but what the experience of operators and engineers can be used to revise these rules advantageously.

There are, without doubt, errors in the preliminary draft. For example, there is the authority granted by the present code to aeronautic associations to examine pilots and issue licenses which can very easily lead to a monopoly and complete control of aviation in any country in which such associations exist.

AUTOMOTIVE INDUSTRIES will be pleased to receive any suggestions for the revision of the new regulations as published in this week's issue, and will forward them to the Inter-Ministerial Commission of Civil Aeronautics.

Government Insisting on Quick Settlement

Contractor Must File Claims by June 30 or Submit Them to Slow Court of Claims

DETROIT, April 8—Manufacturers must present their war claims before June 30. Settlement of the $1,500,000,000 war claims in the Detroit district continues to progress slowly, so slowly in fact that the local claim adjustment boards have issued a warning designed to stir manufacturers tardy in filing their claims into renewed activity.

On and after June 30 local boards will receive no more claims. Contractors with informal contracts must file before that date or their claims automatically became invalid. Contractors with formal claims will be denied the assistance of the claims board after that date and must seek redress in the Court of Claims at Washington.

Inasmuch as the Court of Claims is a slow-working organization, only last week approving a claim for $1,800 filed in 1876, and still having many civil war claims pending, the disadvantage of being obliged to go before this court for settlement is too plainly apparent for the tardy contractor to fail to perceive and the government claim officials here hope the warning will cause him to double his accounting force if necessary to get his documents ready for immediate filing with the respective boards.

Ordnance and quartermaster claim boards thought the bulk of their adjustment work would be settled by April 1. April 1 is here and passed, however, and figures at ordnance headquarters show that on April 1 only 13 per cent of the total 270 claims have been passed and approved by Washington. Approximately 25 per cent have been passed by the local board from 58 per cent of the total which have been filed.

Although the ordnance, quartermaster and aircraft claims boards have several hundred experts at work aiding the manufacturers in preparing reports, inventories and other data required by the government before settlement is made, the work continues to be slow, owing to inability of the contractors themselves to produce the necessary information. Poor accounting and cost system work in the plants is the cause, and in numerous instances the government experts have been obliged to take the books of firms and audit them completely from the day the first purchase was made for contract work until the last job was completed.

The Aircraft Claims Board is making better progress than either the quartermaster or ordnance divisions. This is due to less rigid requirements and the fact that the companies with which this department is dealing are larger and better organized than the others. This board has passed and received settlement on approximately 55 per cent of its total claims, to date having paid out in the neighborhood of $90,000,000. Seven hundred claims remain to be filed and passed upon, however, among them being those of the Packard, Lincoln, Ford, Fisher Body, Cadillac, Buick, Willys-Overland and C. R. Wilson Body Co.

The majority of the sub-contractors' claims have been adjusted by this board, and it is now devoting its entire effort in getting the main contracts in line for adjustment.

Unsettled Steel Price Halts Buying

Makers Waiting for Agreement Between Railroads and Steel Committee and Doing Little

DETROIT, April 7—Until the railroad administration and the steel committee agree on the price the railroads must pay for steel, the automotive industry will continue its present hand-to-mouth buying policies. While the recent price decision fixing a minimum steel price caused increased buying activity, the larger automotive plants continue to buy just what steel they need when they need it. But when the railroads, the nation's greatest steel consumers, get into the market, there will be a demand for steel sufficient to force the automobile, truck, tractor and parts makers to purchase in greater quantity.

When steel prices were set three weeks ago, scores of companies placed orders they had been holding back since Dec. 31, assured that the price would probably take a drop when the cost was fixed April 1, and holding that business conditions during the first few months of the year, would be far below normal, owing to cancellation of government contracts and the general reconstruction depression following the termination of the war. The companies arranged their production schedules for the first few months in accordance with this belief but planned for increased production from April on. When the steel price was fixed the companies were obliged to release these orders which they were withholding, and they did this knowing that from a business standpoint it would be impossible to keep them pigeon-holed much longer. The release of these orders stimulated the market to some extent. These releases were bidding fair to create a general buying movement, and this movement was gaining considerable momentum until the railroad administration upset the equilibrium of the market by holding out for a still lower price.

Metropolitan Section of S. A. E. Discusses Heavy Oil Engine

NEW YORK, April 10—Heavy oil engines, including both the hot surface and the Diesel type, were the subject of discussion at last night's joint meeting of the New York Branch of the American Body of Mechanical Engineers and the Metropolitan Section of the Society of Automotive Engineers, which was held at the Automobile Club of America. Dr. Chas. E. Lucke of Columbia University presided. Among the papers presented was one by Mr. Dean of the Bureau of Mines on the fuel situation, which handled the subject in a statistical manner, and one by J. H. Hunt of the Dayton Electrical Laboratories Co., dealing with some experiments on fuels carried out by the Delco organization. The other papers related to the hot surface type engine and to the Diesel marine and Diesel stationary engines respectively. Little time was left for discussion.

One point brought out at the meeting was that the more abundant the fuel the more difficult it is to build an engine suitable for burning it. In the paper by Mr. Dean it was pointed out that the constituents of crude petroleum suitable for fuel purposes are separated by distillation into five parts, namely, gasoline, kerosene, gas oil (or fuel oil distillate) and light and heavy residual fuel oils. The production of these various fuels for 1918 had just been determined, although the figures available were only the preliminary ones. These were as follows: Gasoline, 3.6 billion gallons; kerosene, 1.8 billion gallons; fuel oil 7.3 billion gallons. No official figures were yet to hand as to the proportions of the different grades of fuel oil, but it was estimated that the total was made up of 1.5 billion gallons of gas oil; 2.0 billion gallons of light and 3.8 billion gallons of heavy residual oil.

Automotive Industries

Post Office Wants 10 Planes

Asks Bids on Multi-engined Machines of Commercial Type—The Specifications

WASHINGTON, April 8—New specifications for ten multi-engine airplanes of strictly commercial type and particularly adapted for carrying mail were issued to-day by the Post Office Department, which is asking manufacturers for bids. The specifications are general, allowing the manufacturers wide latitude of design and construction, and are the result of many views gathered from pilots, airplane makers, aeronautical engineers and manufacturers. Consideration will be given to planes of two, three or more engines connected on one shaft or set in the wings or central fuselage, or both, and with the minimum capacity of 1500 lb. of mail. Preference, however, will be given to planes capable of carrying 2000 to 3000 lb.

The Post Office is especially desirous of securing a plane with a very low landing speed either with speed structurally inherent in the machine or accomplished mechanically, with a cruising speed of 90 to 100 m.p.h. and a cruising radius of about 6 hr. with normal load. A service ceiling of 15,000 ft. is desired. If the planes are built around Liberty or Hispano-Suiza engines the department will furnish the engines.

It is expected that a plane with a carrying capacity of 1500 lb. of mail and 6-hr. cruising radius will not exceed 100 ft. in the wing span. If placed in the wing, engines must be safely accessible to mechanics for minor repairs in the air, and each engine must be equipped with independent and, as far as possible, dual gas, oil and ignition systems.

Bids will be opened on June 2, and it is expected that planes will be ready for delivery within 6 months after letting the contracts.

Bidders are to agree to furnish the planes in lots of six as often as requested at the price specified originally up to June 30, 1920, and must also submit price lists of spare parts and satisfactory bonds with the bid. The time of delivery will count as an important factor in making the contract awards. Following are the general requirements and complete specifications as provided by the Post Office Department:

GENERAL REQUIREMENTS

1. *Fundamental Requirements.* Should be a radical departure from military designing, making the following qualities of primary importance:
   a. Inherent stability in power and glides.
   b. Machine to be balanced for cruising speed, altitude 6000 ft.
   c. Controllability and wide vision.
2. *Performance* (Normal Load).
   a. Efficient cruising speed of 90-100 m.p.h. at 6000 ft.
   b. Cruising radius of 5 to 6 hours.
   c. Buoyancy speed of 50 m.p.h. *or less.*
   d. Low landing speed either inherent or mechanical.
   e. Ceiling of about 15,000 ft.
   f. Capable of horizontal flight or climb on one-half normal maximum power.
3. *General Requirements.*
   a. Two or more motors.
   b. Mail load of 1500-3000 lb. at 17½ lb. per cu. ft.
   c. Crew of one pilot and one mechanic on two-motored planes, and two pilots and one mechanic on three-motored planes.
   d. A method of retracting or hinging wings for storage with wing spans over 80 ft. Optional.
   e. Overall height of 18 ft.
   f. To be capable of easy assembly and disassembly.

DETAILED CONSTRUCTION

1. *Power Plants.*
   a. To be independent power plants.
   b. Accessible for major repairs or removal.
   c. Accessibility for minor repairs during flight.
   d. An approved motor starter system.
   e. Complete radiator shutters adjustable from pilot's seat.
   f. A compression release to be provided for each motor.
2. *Fuselage.*
   a. Preferably a removable mail cage which may be drawn up into fuselage recess.
   b. Steerable tail skid to be optional with builder.
   c. Two tail skids to be provided in tandem; that is, one behind the other, with universal joints, if practicable.
   d. In flight, fuselage to withstand a loading of 30 lb. per sq. ft. on horizontal tail surfaces and 20 lb. per sq. ft. on vertical tail surfaces.
   e. Fuselage to have landing factor of safety of 12-15.
   f. Accessibility of all tanks, leads, controls, etc., during flight.
   g. Variable loads at center of gravity.
3. *Wings.*
   a. Approved construction.
   b. Factor of safety of 6.
   c. Extra strength wing skids hinged with shock absorber of rubber.
4. *Landing Gear.*
   a. To have a factor of safety of 15 in all members.
   b. Center of gravity to be as far back of landing gear as possible.
   c. Elimination of any tendency to nose over.
   d. Landing gear to give adequate support to motors.
5. *Controls and Control Surfaces.*
   a. "Dep."
   b. All controls to be readily accessible for maintenance and repair.
   c. All control surfaces to be balanced where necessary for easy handling.
   d. Emergency control to be provided with removable stick.
   e. Variable horizontal stabilizer to be provided and balanced at neutral point with standard load.
   f. Internal controls designed to be free from danger of ice.
6. *Gas and Oil.*
   a. An independent gas and oil supply for each motor, with intercommunication leads.
   b. An absolutely reliable gas feed system such as provided by mechanical vane pumps and central hand pump as auxiliary.
   c. Accessibility to all valves and leads, both oil and gas, for repairs while in flight.
   d. Strongly anchored tanks.
   e. All leads to be protected against vibration.
7. *Safety and Comfort of Crew.*
   a. Pilot and pilot mechanic to be placed behind main loads, or preferably to

Protest Prohibition of Imports

Importers of American Cars in France Want Bars Let Down—Would Reduce Tariff

NEW YORK, April 9—French importers of American cars have lodged a complaint with the American Peace Commission regarding the present prohibition of importation into France, and have outlined their position in a letter addressed to C. C. Hanch, who is at present in Europe as the representative of the N. A. C. C.

The complaint comes from the *Groupement des Importateurs d'Automobiles Americaines*, and urges the speedy abandonment of the prohibition law on the plea that competition is needed by those who sell French cars, those who make them and those who buy them. The letter suggests a reduction in customs duties, but would have a comparatively high duty for a time to protect French industry, with a reduction as the industry builds itself up. The letter follows:

In the interest of the importers into France of American automobiles, we desire to bring to your notice the situation which is brought about by the embargo existing in France at the present time, and to expose to you our ideas as to the means of alleviating this situation in the interest of:
1. The American automobile manufacturers.
2. Importers of American cars and their French dealers, and
3. The French public in general.

Before the war the customs duty on American automobiles was frs. 750 per 100 kgs. Now, on June 24, 1916, the tariff was increased to 70 per cent *ad valorem* on the value of the goods, augmented by all charges for the transportation, war and maritime insurance; this in order to protect French industry, as all the factories were occupied on war work. At this rate a car costing, say, frs. 8500 in America would pay about frs. 10,000 duty. On April 1, 1917, the French government passed a law prohibiting, purely and simply, all importations of cars of foreign manufacture.

As long as hostilities continued we submitted to this state of affairs, considering them inevitable and necessary to the successful prosecution of the war. Our most ardent desire was the final triumph of the Allied cause.

During this period we and our numerous agents scattered over the whole of France were obliged to live and to keep our business open in spite of the absolute impossibility of trade. We waited patiently and did our best to induce the manufacturers to do the same, thinking that when once the war was successfully terminated we should be allowed to immediately recommence business and develop the sale of American cars in France.

Now the Minister of Industrial Reconstruction in France declares, in his discourse of Feb. 14, 1919, that everything must be done in order to protect the French automobile industry and to stop the inundation of the markets with American automobiles before the French manufacturers are ready to deliver.

The fallacy of this is evident and made manifest by the fact that the French manufacturers are already advertising that their new models are ready for sale to the public.

The reason for the prohibition can therefore not be attributed to the cause mentioned above, but rather to the fact that

War Contracts Settlement Plan Outlined by War Department

Claims Board Offices All Over Country for Speedy Adjustment—Provision for Raw Material, Work in Process, Interest and Profit

WASHINGTON, April 7—In order to further explain the War Department's method for adjusting and paying contracts, Benedict Crowell, Assistant Secretary of War, has again outlined the system adopted by the War Department. His explanation was made in response to a request by the Treasury Department.

The War Department is ready to terminate any claim if the contractor has agreed to terminate production to the extent requested by the War Department, and will waive all claims to prospective profits on uncompleted portions of the contract. Raw materials, component parts and work in process will be considered in adjustments to an amount not exceeding the uncompleted portion of the contract. Interest will be allowed at 6 per cent on borrowed money, and profit will be allowed up to 10 per cent on work in process. Cost of terminating unperformed sub-contracts will be allowed. The contractors are requested to present statements of claims promptly to their proper claim boards. Following is the complete statement:

ADJUSTMENT AND PAYMENT OF WAR DEPARTMENT CONTRACTS

The following questions have been asked by the Treasury Department:

First: What compensation may contractors safely expect to receive on the termination of war contracts, and

Second: How may that compensation be secured?

Shortly after the signing of the armistice thousands of contractors were asked to reduce or suspend production under war contracts and to negotiate the terms of their final settlement.

Many of these contracts were formal written agreements, but others had not been drawn or signed in the exact manner prescribed by law. While payments were made for finished articles or supplies delivered under both formal and informal agreements, it was impossible, in the absence of remedial legislation, to recognize any obligation to contractors on account of anything done in connection with any part of an informal agreement which had not been fully performed. The remedial legislation was introduced in Congress on Dec. 7, 1918, and became a law on March 2, 1919.

As a result of this legislation, the War Department is now able to adjust and settle all of its war obligations, both formal and informal, and is prepared to do so with the greatest possible speed. The Department desires to make these settlements by voluntary agreement wherever possible, and to avoid litigation.

The Department is ready to adjust every agreement on the basis set out in paragraph 7 hereof. If the contractor agrees to that basis he can secure payments with little or no delay because the Department is prepared to make partial payments in the manner set out in paragraphs 8 and 9 hereof, in those cases where a final adjustment of every item would involve considerable delay.

The Department is prepared to carry on negotiations with great speed, and has stationed in the leading cities of the United States, negotiating officers, agencies or boards, so that each contractor can adjust his own contract near his own place of business. A list of these boards is attached hereto. No final adjustment of War Department obligations can be secured, however, unless the contractors will co-operate with the Department.

The process and basis of effecting a settlement is as follows:

1. Every contractor should present a statement or claim which should set out the amount of his expenditures and obligations, the amount and character of materials, supplies and property which he has, the amount which he believes the United States should pay if it takes title to all this material and property in its present condition, and the amount which the contractor believes the United States should pay if the contractor retains this material and property.

2. If any sub-contracts or other items or elements are involved with reference to which the contractor cannot, at the present time, state any final and definite figure, he should at least give such information in connection therewith as is presently available.

3. Where the original contract is a formal one, executed in the manner prescribed by law, this statement or claim should be presented in such place and form as the Supply Bureau which made the contract shall designate. Information as to form and place of filing can be secured from any contracting officer, board or agency within that Bureau.

4. If the original agreement is an informal one and an adjustment thereof is to be made under the Act of Congress of March 2, 1919, the contractor should file with the Claims Board of the Bureau with which the agreement was made, a formal claim, setting out the nature, terms and conditions of the agreement and the amount of money claimed. Proper addresses of these Claims Boards are as follows:

Ordnance Claims Board, War Department, Washington.

Claims Board, Air Service, War Department, Washington.

Claims Board, Chemical Warfare Service, War Department, Washington.

Claims Board, Construction Division, War Department, Washington.

Claims Board, Director of Purchase, War Department, Washington.

Claims Board, Signal Corps, War Department, Washington.

Claims Board, Office Chief of Engineers, War Department, Washington.

(Claims based on agreements with the Quartermaster Corps should be addressed to the Claims Board, Director of Purchase, as above.)

5. Forms for stating claims on informal agreements can be secured from any contracting officer, supply officer, Claims Board or negotiating body of any Bureau at any part of the United States, and these officers, Boards or bodies will give the contractors information and instruction concerning the manner of filling out these claims.

6. After the contractor's claim is presented, the facts therein stated are investigated and verified and negotiations are carried on to fix the terms of final settlement. When these negotiations are completed, the final settlement is made by a supplemental agreement based upon the original contract, if that contract is a formal one executed in the manner prescribed by law, or by an award under the Act of Congress of March 2, 1919, if the original agreement is within the terms of that Act.

In case any contractor is in doubt as to whether or not his agreement does or does not come under the terms of the Act, he can get immediate information by inquiring from the appropriate Procurement Bureau in Washington, or from any of its agencies throughout the United States.

7. If the contractor has agreed to terminate production to the extent requested by the War Department, and will waive all claims to prospective profits which he might have made had the uncompleted portion of his contract been performed, he will be paid:

(a) For raw materials, component parts and work in process on hand in an amount not to exceed the requirements of the uncompleted portion of the contract, the cost thereof plus inward handling charges, plus overhead directly applicable. If this full payment is made, title and possession of the materials, parts and work in process shall be transferred to the United States. If by agreement the contractor retains title to any of this material, parts or work in process, the agreed value thereof shall be deducted from the amount otherwise payable.

(b) A remuneration or reward ordinarily fixed at

(1) Interest at the rate of 6 per cent per annum on money invested in raw materials and component parts, or if the money was borrowed, then interest actually paid, and

(2) 10 per cent profit on work in process.

(c) An amount equal to all money which the contractor is compelled to expend to terminate and discharge unperformed sub-contracts or commitments properly made for the purpose of performing the uncompleted portion of the contract.

(d) Such amounts as are necessarily spent in connection with the care and custody of property involved from the date that the contractor has suspended production down to the time of settlement.

(e) On account of facilities, machinery and equipment acquired for the purpose of performing the contract, and the cost of which would have been recouped had the contract been performed,—an amount which shall be computed as follows: From the cost deduct the present value, and of the balance take the same proportion that the uncompleted part of the contract bears to the whole.

(f) Any other special item of expenditure which, in the opinion of the Secretary of War or any duly authorized officer, is proper.

For the purpose of determining the exact amount payable under paragraphs (a) and (b) above, raw materials and component parts have been defined, for the purpose of contract termination, as follows:

"All of those materials, parts, articles and supplies, direct and indirect, which are in substantially the same condition, nature or state of fabrication that they were in when they were acquired by the contractor, and in the production, fabrication or assembling of which the contractor has neither employed nor performed labor other than labor connected with custody and handling."

(8) It frequently happens that the determination of all of the amounts which may be payable in accordance with the terms of the foregoing paragraphs, and the determination of the most economic disposition which can be made of all property involved in final settlement, requires a considerable time, but that there are many items with respect to which a final adjustment can readily be made. It further happens that it is often of economic value to make an immediate adjustment and payment of some of the items involved without waiting for an adjustment and payment of all. Under such circumstances, if the contract is a formal one, a supplemental agreement will be entered into which will fix the basis of final adjustment as outlined in paragraph 7, and will provide for the payment of each item involved just as rapidly as the amount payable is determined. In this way, various raw materials, supplies and work in process can be put to an immediate use, and the contractor's plant kept in production, and labor retained in employment and the contractor's obligations on different sub-contracts and commitments finally disposed of just as rapidly as tentative agreements are reached with the sub-contractors and commitment men.

9. When the agreement is an informal one and is paid by award under the Act of Congress of March 2, 1919, if it is found that a situation exists similar to that described in paragraph 8, partial awards are made, and items are adjusted and discharged just as rapidly as the amounts to be paid are determined.

10. The attention of all contractors should be directed to the fact that where their agreements are informal, their claims must be filed prior to June 30, 1919; otherwise they are, by the Act of Congress of March 2, 1919, forever barred from any relief.

11. There is no occasion for any contractor to have any doubt about his ability to secure an adjustment on the basis above outlined. Although several months have passed since the contractors were requested temporarily to suspend production, there are thousands of contractors who have as yet presented no statement or claim showing what they want. If there are any reasons why any contractor cannot state his full claim and the disposition which he desires to have made with reference to every item thereof, there is no reason why he should not present as much of his claim as possible in order that the necessary investigations and negotiations can be proceeding. The organization which is handling this matter is essentially civilian in character, and composed of men who have come into the Department merely for the purposes of the war and who remain in this work only at a very great personal sacrifice and at the urgent request of the department. Contractors who desire to avail themselves of the existing organization in the department for the settlement of their claims must present them prior to May 15, 1919, as after that date the method of handling these claims will necessarily be changed through the impossibility of continuing the present personnel.

12. For the purpose of supervising and securing uniformity in regard to settlement of formal contracts, and for the purpose of making awards under the Act of Congress of March 2, 1919, the War Department Claims Board has been created, and this board, or its

members, are in constant duty in Washington. From time to time this board issues detailed instructions and directions governing the methods of making settlements. These are available to any contractor at any time. Actual negotiations under these instructions and rules are, however, carried on with the contractor by the various agencies scattered throughout the country.

BENEDICT CROWELL.
The Assistant Secretary of War, Director of Munitions.

56,000,000 Acres Added for Tractor Possibilities

WASHINGTON, April 5—The possibilities of a steadily increasing farm tractor business are indicated in the announcement made to-day by the Department of Agriculture that more than 56,000,000 acres have been added to the country's aggregate crop acreage in the last 10 years. The figures given out show that the aggregate last year totaled 367,738,000 acres, or 605,840 square miles. This covers more than one-fifth of the land area of the United States. The number of farms is estimated at 6,717,000.

Texas has the largest aggregate crop acreage, with 25,328,000 acres, or a little more than one-sixth of her total land area. Kansas is second, with 22,588,000 acres, or almost half of her entire land area. Illinois is third, with 21,727,000 acres, or about three-sevenths of her land area. Iowa, in fourth place, is very close to Illinois, with 21,613,000 acres, which is about three-sevenths of her land area.

The aggregate crop acreages, which included those of corn, wheat, barley, oats, rye, buckwheat, potatoes, sweet potatoes, tobacco, flax, rice, hay, cotton, peanuts, kafirs, beans, broom corn, hops and cranberries, and the number of farms by States follow:

56,000,000 FARM ACRES INCREASE

State	1918	Farms
Maine	1,633,000	60,000
New Hampshire	592,000	27,000
Vermont	1,307,000	33,000
Massachusetts	674,000	37,000
Rhode Island	88,000	5,000
Connecticut	601,000	227,000
New York	8,509,000	215,000
New Jersey	1,183 000	33,000
Pennsylvania	8,377,000	218,000

Virginia	5,577,000	195,000
West Virginia	2,351,000	100,000
North Carolina	7,232 000	275,000
South Carolina	6,992,000	190,000
Georgia	12,624,000	330,000
Florida	1,563,000	56,000
Ohio	11,462,000	270,000
Indiana	12,764,000	215,000
Illinois	21 727,000	245,000
Michigan	8,808,000	209,000
Wisconsin	9,326,000	182,000
Minnesota	16,008,000	157,000
Iowa	21,613,000	215,000
Missouri	15,232,000	275,000
North Dakota	18,298 000	95,000
South Dakota	15,845,000	95,000
Nebraska	18,646,000	135,000
Kansas	22,588,000	180,000
Kentucky	6,922,000	270,000
Tennessee	7,252,000	260,000
Alabama	10 569,000	280,000
Mississippi	8,089,000	295,000
Louisiana	4,981,000	123,000
Texas	25,328,000	450,000
Oklahoma	13,744,000	220,000
Arkansas	7,399,000	230,000
Montana	4,845 000	36,000
Wyoming	1,569,000	15,000
Colorado	4,060,000	60,000
New Mexico	1,485,000	45,000
Arizona	477,000	13,000
Utah	1,095,000	24,000
Nevada	448,000	3,000
Idaho	2,136,000	38,000
Washington	3,649,000	70,000
Oregon	2,768,000	52 000
California	5,927,000	98,000
United States	367,738,000	6,717,000

Farm lands in the United States are steadily increasing in value. The Department of Agriculture reports the average grade of plow lands was worth about $74.31 per acre on March 1 this year, compared with $68.38 a year ago, $62.17 two years ago and $58.39 three years ago.

Values show the greatest percentage increase during the last year occurred in the South Atlantic States, in the Carolinas and Georgia, and extended to Alabama, Kentucky and Arkansas. Small or no increases were made in the New England States, the Pacific Coast States and Louisiana, Texas, Kansas and Montana. Material increases were reported from Nebraska and South Dakota.

Iowa's plowing lands stand first in value, her average being $169 per acre, followed by Illinois with $144, California with $121, and Indiana with $100. Alabama reports the lowest average of plow lands at $24 per acre, and Mississippi next at $25.50.

Canada Takes Most American Tractor Engine Exports

WASHINGTON, April 5—Canada was the largest user of American farm tractor engines in the month of January. A total of 2711 engines, valued at $2,799,852, were exported from the United States into Canada. France was the next largest user, taking 584 engines, and Italy was third with 242. Following are the statistics:

Countries	Number	Value
France	584	$826,207
Greece	105	63,700
Italy	242	448,635
Norway	1	2,208
Portugal	22	7,032
England	29	39,408
Canada	2,711	2,799,852
Guatemala	1	1,525
Mexico	27	31,868
Jamaica	1	1,890
Cuba	30	20,393
French West Indies	2	3,750
Argentina	2	3,800
Brazil	2	2,383
Chile	15	24,750
British Guiana	11	12,904
Peru	6	18,138
Venezuela	3	2,400
China	2	2,378
Australia	3	1,861
New Zealand	36	27,126
Philippine Islands	33	45,756
British South Africa	28	22,016
French Africa	1	325
Total	3,897	$4,410 305

Interstate Highways Approve Federal System

KANSAS CITY, April 7—Twenty-eight interstate highway associations have so far qualified for membership in the Associated Highways of America. They represent about 50,000 miles of marked highways, reaching to nearly every part of the United States, to the borders of Canada and Mexico and to the coasts. By the time Congress convenes the organization will be further strengthened, and it will back a bill for a Federal Highway Commission, probably one of the bills already introduced. The Associated Highways of America will present the combined system of marked highways of its membership as the plan for Congress to adopt, for the Federal system to be built and maintained by the Government.

Northern Foundry Doubles Force

MARINETTE, WIS., April 7—The Northern Foundry Co. will double its operating force at once.

Pulcher Heads N. A. C. C. Truck Show Committee

NEW YORK, April 9—Martin L. Pulcher, vice-president of the Federal Motor Truck Co., has been appointed chairman of a motor truck show committee of the National Automobile Chamber of Commerce to arrange for proposed exhibits of trucks in New York and Chicago next winter during the same weeks as the national passenger car shows. Associated with him on the committee are A. J. Wipple, general sales manager of the Diamond-T Motor Car Co., Chicago; David S. Ludlum, president of the Autocar Co., Ardmore. Several additional members of the Motor Truck Committee have been appointed as follows: David C. Fenner, Mack Bros. Motor Car Co., and R. H. Salmons, Selden Motor Vehicle Co. F. W. Fenn, who has handled the Rural Motor Express Department of the N. A. C. C., has been made secretary of the Motor Truck Committee.

D. C. Fenner has been appointed chairman of the committee to co-operate with the S. A. E. in furthering truck standardization work, and associated with him are Francis Davis (Pierce-Arrow), F. A. Whitten (General Motors), E. M. Sternberg (Sterling), F. F. Beall (Packard). Another committee has been appointed to revise the standard service and repair parts policies of the N. A. C. C. as they relate to trucks. Members of the committee are: Chairman, E. T. Herbig (Service), F. H. Drew (Packard), W. M. Ladd (Pierce-Arrow), A. B. Cumner (Autocar), F. H. Harris (Republic).

—

Unsettled Steel Price

(*Continued from page* 816)

There is a general attitude of doubt displayed by the purchasing agents. The trade is demanding lower prices, the manufacturers of cars and trucks are demanding lower prices. The parts makers are demanding lower material prices, and this is the situation right at present. In normal times the steel mills should be running 100 per cent capacity at this time of the year. The companies should have the major portion of their 1919 steel purchased or contracted for. The companies, however, have but little steel on hand and are buying in small lots. The mills, purchasing men declare, are only operating at from 50 to 70 per cent capacity.

While some are holding back for an expected drop, others declare this reduction is impossible. But whether the market goes up or down, the automotive industry is going to wait until a more stable condition prevails. It is believed that pronounced buying will send the price up, because of high fuel cost, high labor prices and high overhead which are the big elements which will cause a further upward movement at the mills. High labor and raw material cost prevent such a reduction, they declare.

While the automobile passenger car business has been flourishing from the moment the big plants got back to peace production, the truck industry has been decidedly backward. Makers of axles and other parts declare they are prepared to do twice the truck business they are doing at present.

The truck makers, however, tell of good buying business and fair production schedules, but the parts makers hold that the truck business is not what it could be. Competition in the truck field is decidedly keen and new truck companies are springing up with regularity both in Detroit and other parts of the state. This competition is shaping itself into a matter of efficiency and price. The best truck at the best price is going to get the business, and knowing this the truck makers are endeavoring to shave prices as low as possible conducive to reasonable profit.

This policy has caused curtailed production, inasmuch as the makers hoped steel price reduction would aid them in decreasing manufacturing costs and permit the establishment of lower retail truck prices. There is no question but what steel price fixing has given this department of the automotive industry greater confidence than the others.

—

Protest Prohibition of Imports

(*Continued from page* 817)

the manufacturers fear and exaggerate the danger of American competition. We know ourselves that competition never had any baneful or injurious effects for the consumer or the producer. We possess proof of this in America, where competition is extremely acute, especially in the automobile industry, and it is an incontestable fact that most automobile manufacturers in the United States are in a prosperous and flourishing condition. It is only necessary to glance at the retail price of automobiles in America to appreciate the advantage which the general public derives from this competition.

As long as the importation of American automobiles is prohibited in France the French manufacturers will have every opportunity to sell at excessively high prices and therefore make large profits, to the detriment of the French public.

We do not ask to immediately return to the pre-war customs tariffs, as we understand perfectly that it is necessary to protect the French automobile industry; but we do not admit that it should be protected in such a manner as to be prejudicial to the interests of the French public and the good will and friendship which exists between the two sister republics. We only desire to be allowed to compete in a fair and loyal manner with the French constructors.

We would ask you, therefore, to assist us in every way possible to obtain, without further delay, the cancellation of the prohibition order at present existing, and that we be advised immediately as to the date of its ultimate suppression.

In order to facilitate the abolition of this order we would be disposed to accept the imposition of customs duties which would commence at a certain rate and gradually decrease each quarter until a normal rate is attained. These duties will be calculated upon the purchase price in the United States, in the same manner as French goods exported to America, which are only taxed upon the invoice value in France.

The customs tariffs between the United States and France should be established on a reciprocal basis. The tariff in force at the present time, which is imposed on the actual cost of the goods delivered at a French port, places the English, Swiss and Italian manufacturers in a far more advantageous position than the American, as the first named have very little freight to disburse, whereas the cost of transportation from the United States is, and probably will be for some considerable time, extremely enormous.

With a scale of customs duties based upon the proposition indicated in this letter, French industry would be protected in an efficacious manner without undue hinderance to our numerous dealers throughout France and would at least permit them to earn their livelihood and contribute to the support of the workmen they employ.

In like manner this would conduce to maintain the good will and friendship which should endure between France and the United States after the substantial assistance rendered by America toward the successful prosecution of the war.

It is certainly in the interests of the French public that the importation of American automobiles into France should be permitted without undue let or hindrance, otherwise the French manufacturers will continue to maintain the present exorbitant prices.

It might be argued that the French constructors do not in any way acquire large profits, but we feel assured that if importation from America is authorized they would immediately reduce their prices to a considerable extent and they would so adapt their methods of fabrication to those practised in America that they would prosper in spite of foreign rivalry. As mentioned previously, competition is salutary and, in our opinion, necessary.

The fact must not be lost sight of that the American factories have been more or less exclusively employed during the past year or so upon work in connection with the war, and in view of this they are practically in the same situation as the French factories. In this way they do not constitute a very formidable menace to French industry, as they will be obliged to limit the exportation of their products in order to cope with the demands of the American public. Another fact which might be noted is that the cost of raw material has increased considerably in the United States, so that it will be a practical impossibility to revert to pre-war prices.

New Officials of S. A. E. Metropolitan Section

NEW YORK, April 10—At the monthly meeting of the Metropolitan Section of the Society of Automotive Engineers held last night at the Automobile Club of America, officers for the ensuing year were announced as follows: Chairman, A. C. Bergmann; treasurer, Lars G. Nielson; secretary, Austin M. Wolf. H. M. Crane, F. G. Diffin and Alfred Reeves form the board of governors.

—

Postoffice Wants 10 Planes

(*Continued from page* 817)

be placed over loads in streamline at at top of fuselage.

b. That provisions be made for protection against bad weather.

c. A passage way to be provided, so that vital parts are accessible to mechanic in flight.

d. That suitable slideways and eyes be provided for belt and snap hook to be worn by mechanic in making repairs in exposed places.

e. Suggested that streamlining on exposed power plants be hinged at front and of sufficient width and length to provide shelter for mechanic while working on motor. To be held out by suitable, adjustable strut.

f. That room be available in control cockpit for map boards, instruments and radio controls.

g. That a good fire extinguisher system be provided, such as Pyrene or equal, tubed by suitable leads to gasoline tanks and all motor compartments, to be operated from control cockpit.

h. That pilot's seat be adjustable in relation to controls.

Bidders are requested to submit with proposals full information and particulars, as indicated below, of the ships that they propose to furnish.

a. *General Arrangement Drawings*, showing plan, side and front elevations, drawn to a scale of one-twelfth or one twenty-fourth full size.

b. *Main Dimensions*. Areas of maian surfaces, areas of control surfaces, stagger, dihedral, incidence, span, chord, gap, gap-chord ratio, setting of stabilizer to wing chord.

c. *Weight Schedule and Balance Diagram*, giving weight of power plant and accessories, fuel and oil, mail load, passenger and pilot and instrument loads, structural weight subdivided into groups. Balance diagram for ship with normal load, showing position of center of gravity.

d. *Performance Estimates*. Speed, climb, speed at altitude, endurance at full power ground level, endurance at 6000 ft. at cruising speed.

e. *Power Plant*. Fuel and oil consumption and brake-horsepower curve for engine other than Liberty motor. Diagrams and descriptions of gasoline system, cooling system, oil-circulation systems.

f. *Stress Diagrams* for Wing Truss, Fuselage with air and ground loads, Landing Gear.

g. *General Assemblies of and Structural Information* on wing structure, fuselage and landing gear, with details of special construction, important fittings, statements as to whether streamline wire or cable will be employed, etc.

Materials and Shop Processes. All materials and shop processes employed should be in accordance with either Army or Navy specifications and standards.

Inspection. Airplanes in process of construction shall be open to the inspection of the Post Office Department.

Tests Prior to Acceptance. One machine to be sand-tested at the option of the Post Office Department, in accordance with the Army Specifications. One machine to be tested for performance, landing speed and controllability—tests to be carried out by the Post Office Department.

Unless otherwise provided, remaining airplanes under the contract will be accepted, based upon inspection complete at the works and on inspection of complete drawings. This is for the purpose of checking parts, alignment, completeness and satisfaction of details. At this time the power plant shall be operated in every detail to the satisfaction of the Post Office Department.

General Motors Plans to Spend $37,398,000

For Additions, Plants and Equipment in Flint, Detroit, Pontiac, Toledo, Etc.

DETROIT, April 3—General Motors Corp. expansion plans for 1919 were outlined to-day by William C. Durant, its president and general manager. Combined, they entail an expenditure of $37,398,000 to be invested in new plants, additions, office and sales buildings and new equipment in Detroit, Flint, Pontiac, Lansing, Saginaw, Toledo, St. Louis, Mo., Janesville, Wis., Bristol, Conn., and Muncie, Ind.

Detroit will get the lion's share of the appropriation, $12,650,000 to be spent here. General Motors expansion here includes a complete new plant for the Cadillac Motor Car Co. division, to be located on Clark and Scotten avenues; a sales and service building for the same company to be at the corner of York and Cass avenues; a $5,000,000 15-story general office building for the General Motors Corp. and all of its subsidiary units, to be located on Cass Avenue, with a four-story research laboratory in the rear; a differential gear and transmission plant; a general bearing and power plant; extensions to the Central Forge Co., and the Northway Motor & Manufacturing Co. plant, all to be located on Holbrook Avenue.

The proposed office building will cover an area of 336 x 482 ft. Four wings will extend from front to rear, and these will be connected by a central wing, this plan offering direct outside light to every office in the building. The ground floor will contain salesrooms for all of the subsidiary companies of the corporation, as well as service stations for the United Motors Corp.

In the center of the building and on the ground floor there will be an auditorium seating approximately 1000, with stage, dressing rooms, etc. It will be used for conventions and other purposes. The main entrance will be in the center. Other entrances will lead from both sides to the main lobby and elevators. There will be 16 passenger elevators in the building. The laboratory in the rear will be 60 x 480. It will be 4 stories high, with approximately 50,000 sq. ft. of office space on each floor. The entire building, including laboratory, will have a floor area of about 875,000 sq. ft., exclusive of corridors, toilets, elevators. It will be strictly fireproof.

Buick and Chevrolet Extension

General Motors will spend $6,715,000 at Flint, where large plant extensions to the Buick and Chevrolet companies are proposed. The remainder of the appropriation will be used to build 1000 homes for employees, with water mains, sewer systems, paved streets, etc. They will be sold to the workers on easy payment plan.

Lansing projects total $2,540,000. A new axle plant will be built and large extensions made to the Olds Motor Works division. At Saginaw, $2,427,000 will be spent in extensions to the central foundry, motor and steering gear departments for the Saginaw Products division and a central heating plant. Toledo will get $543,000 to be invested in extending the transmission department of the Chevrolet Motor Co. branch factory there. A new plant will be built for the St. Louis Woodworking Co. at St. Louis, Mo., as well as large assembling plants for the Buick and Chevrolet division in that city. These improvements will cost $4,135,000.

Janesville, Wis., projects total $4,500,000 and include plant extensions for the Janesville Machine Co., the Sampson Tractor Co. and hundreds of houses for employees. At Bristol, Conn., $1,028,000 will be spent in extending the present plant of the New Departure Manufacturing Co. At Muncie, Ind., $800,000 will be spent in plant extensions and houses for employees.

Mr. Durant also said that Walter P. Chrysler, now president and general manager of the Buick Motor Car Co., Flint, has been made vice-president in charge of all General Motors operations and assistant to Mr. Durant. This new arrangement does not involve any material changes in the policy of the independent management of the General Motors division. The central operating organization headed by Mr. Chrysler will direct the carrying out of the policies of the corporation.

Mr. Chrysler will be succeeded by Harry H. Bassett, as general manager of the Buick. He has been associated with Mr. Chrysler as assistant general manager for several years.

—

Minerva to Supply Truck and Tractor Engines

CLEVELAND, April 6—The Minerva Engine Co., which has been incorporated here under Ohio state laws for $250,000, will engage in the manufacture of truck and tractor engines. The officers and directors are: President, C. S. Goby; vice-president, R. K. Johnson; secretary, L. R. Long. The directors include E. P. Dowling, John R. Dowling, H. F. Eilbert and J. J. Cummings. Offices have been established in the Vickers building.

Experiments and tests are completed and preparations are under way for immediate production. The company expects to give employment to several hundred men. For the present it will make only its Model A engine, which is a 50 hp. machine. It will be manufactured for other lines as well as tractors and trucks.

R. K. Johnson, director of engineering, was formerly connected in a similar capacity with the Garford Engineering Co., and the Gramm Motor Truck Co. He also spent two years in England studying engine design. The engine has a special water-jacket construction, high pressure oiling system and an air cleaning device for purifying the air of dust before it enters the carbureter. A plant will be erected early this spring.

Housing an Important Problem

Cessation of Building in Detroit Creates Serious Shortage of Workers' Homes

DETROIT, April 6—The Detroit Housing Association, of which Frank W. Blair is president, is completing organization of a separate $1,000,000 corporation to build homes for workingmen in Detroit at minimum cost. It is hoped to enlist the aid of every merchant and manufacturer of the city with the view of solving the city's serious housing problem.

Hundreds of Detroiters have walked the streets for months looking for houses and apartments. The present shortage is the result of the cessation of building during the war, in which time 61,999 families have reported to have come to Detroit, while but 28,196 houses were erected. Allan A. Templeton, president of the Chamber of Commerce, declares the plan of building houses on a wholesale scale is the only method which can be pursued in solving the problem.

Detroit companies are vitally interested in finding suitable living conditions for their workingmen. The Ford Motor Co. has solved the housing problem as far as Highland Park is concerned by the inauguration of a realty department and a building and loan association, where Ford employees are encouraged to borrow and build on the easy payment plan. The Ford Co. urges its workmen to build and settle down, and this factor has been successful in cutting turnover.

At Dearborn, Henry Ford is duplicating his Highland Park housing program. His recently incorporated Dearborn Realty & Construction Co. has scores of small homes in the course of construction. This company is contemplating house construction on a gigantic scale. It is expected that the General Motors Corp. will shortly announce a housing project for Detroit similar to that about to be undertaken by the corporation at Flint and Janesville, Wis. The Solvay Process Co., for years past, has been engaged in providing housing for its employees. The Edison Co., American Blower Co., Gemmer Manufacturing Co., Timken-Detroit Co. have also engaged more or less in providing homes.

At Ojibway, Ont., just across the river from Dearborn, the Canadian Steel Corp. is building a second and greater Gary.

—

Contract Cancellations Increasing

WASHINGTON, April 9—Cancellations of aircraft war contracts have increased until 84 per cent of those outstanding Nov. 9, 1918, have been terminated, with 15 per cent delivered since that time and 1 per cent remaining in force. Contracts of the motors and vehicles section have been terminated up to 63 per cent of those outstanding Nov. 9, with 24 per cent delivered since that time and 13 per cent remaining for completion.

Lieutenant Andre Boillot, who will fly at the Indianapolis Speedway, May 31. The machine is a French fighting Spad which was used by Boillot at the front

Bleriot-Spad for Indianapolis

PARIS, March 20—André Boillot will fly the latest type of French army fighting plane during the Indianapolis race meeting on May 31. Young Boillot is the only surviving brother of the well-known Georges Boillot, who was killed in a single-handed fight against seven German planes. Immediately after the death of his brother, André Boillot, who was then serving in the infantry, asked to be transferred to the air service. Within a few months he was at the front and won the Croix de Guerre. For the last twelve months Boillot has been chief test and experimental pilot at the Bleriot factory, and has carried out all the initial trials with the latest French scout machines.

The machine with which Boillot will give exhibitions at Indianapolis is a Bleriot-Spad which was used on the front by the French pilot Fonck. This type of machine has never previously been seen in America.

In addition to coming as an air pilot, it is quite possible that André Boillot will start in the Indianapolis race on a 150 cu. in. Peugeot. If he does this his flying exhibitions will be given either before or after the speed contest. The little Peugeot is a machine which was built in 1914 for a race to be held in France in August of that year. The war prevented that race, and the machines were stored away awaiting better days. Officially Peugeot is unable to take part in the Indianapolis race, but Boillot has secured the loan of one of these small racers and is having it equipped.

Official Indianapolis Entries to Date

NEW YORK, April 7—Ralph De Palma, in his special Packard, equipped with an engine having a piston displacement of 299.2 cu. in., has entered his name for the Indianapolis events on May 31. Louis Chevrolet will also race in a special model which is presumably a Frontenac, although the name has not been disclosed, and has a piston displacement of 299.5 cu. in. Another Frontenac special with a displacement of 299 cu. in. will be driven by Ralph Mulford. Three Duesenberg specials have been entered, one a Roamer-Duesenberg to be driven by Kurt Hitke, the other two by Tom Milton and Ed O'Donel. Earl Cooper will have a Stutz. Besides these, as already reported, W. W. Brown will race in his 24-valve Hudson, R. C. Durant in a Chevrolet, and the two Sunbeams will be piloted by J. Chassagne and Dario Resta, who will take Joseph Christiaens' place.

French Races for 1920

PARIS, March 22—In all probability there will be a Grand Prix road race in France next year. The Automobile Club of France will celebrate its twenty-fifth anniversary in 1920, and intends to mark this happy event by several big demonstrations, of which a road race will be one. No official announcement has been made, but the feeling of manufacturers in general is in favor of road racing next year. In addition to the national race a big speed contest in the neighborhood of Marseilles will be held independently in 1920.

Birmingham Fair in 1920

WASHINGTON, April 5—The British Industries Fair for 1920 will be held at Birmingham, England, beginning the last Monday in February and continuing 14 days. Exhibits will include motorcycles, cars, trucks, accessories and aeronautic accessories and engines, etc. Further information can be secured from the Chamber of Commerce of Birmingham.

Willys Picks Men for Profit Split

TOLEDO, April 3—The committee of ten which is to work out the details of the Willys-Overland Co. 50-50 profit sharing plan, which President John N. Willys recently announced for the Toledo factory, has been appointed. Five members of the committee represent the factory and five the executive departments.

L. M. Ellis is chairman of the committee and A. H. Sarvis secretary. Other members are: H. G. Fitch, sales and service department; Harry Bothart, first assembly department; L. A. Miller, administration building; J. R. Woodruff, polishing and plating department; W. J. Highley, compensation department; Wilfred H. Emery, toolroom; Harry A. Webb, paint shop. The method by which the employees will share in the profits of the company on a 50 per cent basis with the stockholders and the date for the first payments are expected to be announced soon.

289 Refineries in United States

WASHINGTON, April 7—A total of 289 refineries are producing 1,295,115 bbl. of crude oil per day in the United States, according to announcement made to-day by the Bureau of Mines. Following is the list of the petroleum refineries in the United States, with the daily capacity:

State	No. of Refineries	Capacity Bbl.
Arkansas	1	300
California	37	280,870
Colorado	2	1,500
Illinois	11	46 000
Indiana	2	36,500
Kansas	31	71,350
Kentucky	2	2,600
Louisiana	12	67,925
Maryland	4	15,500
Minnesota	1	300
Missouri	5	16,375
New Jersey	4	100,000
New York	4	34,500
Ohio	10	24,360
Oklahoma	79	233,300
Pennsylvania	48	90,935
Texas	26	212,050
Utah	1	800
West Virginia	5	7,700
Wyoming	5	52 250
Total	289	1,295,115

F. W. D. Tractors to Have Canadian Branch

CLINTONVILLE, WIS., April 7—The establishment of a F. W. D. motor truck assembling plant and branch works at Kitchener, Can., was determined upon at a special meeting of stockholders of the Four Wheel Drive Auto Co. at the main offices here. The plan involves the organization of a new and distinct corporation, having a capital stock of about $200,000, practically all of which will be owned by the stockholders of the present company. With this in view, the corporate articles of the F. W. D. company were ordered amended so that it may legally acquire and own stock in other corporations. While details of the Canadian plant project have not been definitely fixed, it is the intention to erect a large machine shop at Kitchener for the assembling of F. W. D. trucks from parts made here and shipped into Canada in bulk.

Willys Starts Profit-Sharing

TOLEDO, April 6—The Willys-Overland Co. has approved two sections of the

50-50 profit-sharing plan under which it proposes to operate. The two sections have been completed by the factory committee of ten to work out the details.

Profits which are to be shared with the employees will be distributed five times annually—in April for January, February and March; in July for April, May and June; in October for July, August and September; in December for October and November.

The other section of the plan outlined defines permanent labor. An employee, to become a profit sharer, must have been six months in continuous service. Absence from work because of illness, injury or on consent of employer, does not affect his continuity of service. Absence, however, without report or satisfactory excuse automatically removes the employee from the continuous service record. Overland men still absent in military service will be considered as in continuous service if they make prompt application for re-employment after their discharge from military service.

Goodyear Council of Industrial Relations

AKRON, April 8—The Goodyear Tire & Rubber Co. has established a Council of Industrial Relations. This will give representation to all employees over 18 years of age, who are American citizens and who have had six months' continuous service or one year's total service with the factory. The council will meet with the factory manager, and is intended to be a broad and comprehensive democratic form of management. About 20,000 employees will be affected.

The council will be composed of an executive council consisting of five men named by the factory manager, the manager and assistant manager of the labor department, two foremen to be selected by all the factory foremen, and six non-salaried employees. All questions of industrial relations will be passed upon by this body. Its first duty will be to formulate a plan to establish a legislative body along the lines of the national congress, which will give representation to all employees eligible to vote.

Carlisle Cord Tire Putting Up Plant

STAMFORD, CONN., April 7—The Carlisle Cord Tire Co. will establish its principal factory here, and has purchased about 10 acres of land, with a frontage of 1000 ft. on Fairfield Avenue and a depth of 400 ft. It is expected to be in operation by Aug. 1.

The main building is to be 250 x 150 ft., cement, steel and glass, of sawtooth construction. The company has had a plant at Andover, Mass., for two years, and intends to continue it in operation, although the main factory and executive offices will be moved here.

Brazil to Spend $500,000 for Aviation

WASHINGTON, April 5—The sum of $500,000 has been appropriated by Brazil for organization of an aviation service, purchase of airplanes, establishment of aviation schools and the buying of various accessories.

Pierce-Arrow Sales Increase 27%

Production Curtailed by War Orders—Aircraft Program Cut Short

BUFFALO, April 8—Gross sales of the Pierce-Arrow Motor Car Co. increased about 27 per cent during the year ended Dec. 31, 1918, or from $32,565,908 in 1917 to $41,354,439 in 1918; and in this period the company produced 8,635 vehicles, of which 1168 were passenger cars and 7467 were trucks. In 1917 the company produced 7703 vehicles, of which 2532 were cars and 5171 were trucks.

The statement for the year ended Dec. 31 last compares with 1917 as follows:

	1918.	1917.
Net profits after depreciation, etc.	$4,273,171	$4,791,274
Estimated war and excess profits and income taxes	1 200,000	1,161,803
Balance	$3,073,171	$3,629,471
Other income	15,601	11,858
Total income	$3,088,772	$3,641,329
Interest	323,032	42,582
Net profit	$2,765,740	$3,598,747
Preferred dividends	800,000	800,000
Balance	$1,965,740	$2,798,747
Common dividends	1,562,500	625,000
Surplus	$403,240	$2,173,747
Previous surplus	2,415,962	242,215
Total surplus	$2,819,202	$2,415,962

The balance sheet as of Dec. 31 last shows:

Assets—	1918.	1917.
Property account	$4,874,350	$5,431,438
Investment in affiliated selling company	40,000	40,000
Inventories	14,582,749	14,837,786
Notes and accounts receivable	4,012,994	3,665,632
Miscellaneous investments and deposits	87,647	86,463
Cash at bank and on hand	2,338,694	1,192,696
Liberty bonds	275,000	634,991

Common dividend payable Feb. 1, 1919	312,500	......
Surplus	2,819,203	2,415,962
Total liabilities	$26,278,617	$26,084,912

The report to the stockholders says:

"The energies of your company during 1918 were absorbed mainly in war activities under growing demands from the War Industries Board. Passenger car production was curtailed early in the year and was practically deprived of raw material from about August 1 on. Trucks for war purposes were given precedence over trucks for commercial purposes in an increasing ratio as the year advanced. During the latter part of the year it was impossible to secure material for either commercial trucks or passenger cars.

"Coincident with its increased demands for trucks for war purposes, the government besought us to enter the aircraft field. In August the Aircraft Production Board entered into a contract with your company for the manufacture of a large number of Hispano-Suiza airplane engines, deliveries of finished product to begin in 1919. This aircraft program, contemplating the use of two-thirds of our existing machine facilities, seriously interfered with the use of such facilities for the production of war trucks, and additional producing agencies had, therefore, to be created, details in regard to which are given under a later caption.

"With the signing of the armistice on Nov. 11, this entire program of production for government purposes was cut short. Further preparation for aircraft production came to an abrupt end with the cancellation of the aircraft contract—but, inasmuch as this contract contemplated reimbursement of your company for all outlays and there can be no doubt of the government's intentions in this matter, the auditors have set up no reserves against this investment, which appears among accounts receivable. Likewise were canceled the bulk of the truck orders for the United States government and part of the truck orders for the French government. This situation is reflected in the unfilled orders on hand Jan. 1, 1919, which were 2,341, as against 5,098 on hand Jan. 1, 1918.

On the other hand, the armistice put an end to the embargo on passenger car material and resulted in a prompt and gratifying revival of passenger car business. Following the armistice, factory night work and overtime was eliminated and steps were otherwise taken to bring operation down to a normal basis. We are now operating on a permanent 48-hour week basis.

Shipping to Central America Permitted

WASHINGTON, April 7—Manufacturers of passenger cars, motor trucks, tractors and accessories can ship freely, without individual export licenses, to Mexico, Cuba, Haiti, San Domingo or to any country in Central America or South America, excluding the colonies of Great Britain and France, according to announcement made to-day by the War Trade Board. Fuel oil and gas oil are still restricted in shipment.

Fuel Oil Contracts Let to Standard

WASHINGTON, April 5—The Shipping Board awarded contracts for 7,500,000 bbl. of fuel oil to the Standard Oil Co. yesterday. This oil is for the operation of vessels under its jurisdiction. The contracts were all for Atlantic and Gulf ports delivery.

Claudel Carbureter to Have American Production

NEW YORK, April 8—The Aeronautical Equipment Co. has contracted with the Claudel Co. of France for the American rights to manufacture the Claudel carbureter. The contract calls for a minimum of 20,000 carbureters for the first year, progressing through a minimum of 100,000 carbureters in the sixth year. The company expects to exceed these figures very considerably.

Foreign Drivers to Arrive Soon

PARIS, FRANCE—(Special Cable)—April 8—Coatalen, engineer of the British Sunbeam Co., and Chassagne, who are to drive Sunbeam cars in the 500-mile Sweepstakes Race on the Indianapolis Speedway, May 31, will sail from Liverpool on April 15. A number of other French drivers will sail from Havre on May 3.

Re-sells Obsolete and Unserviceable Planes to Curtiss

WASHINGTON, April 4—The War Department has resold a number of obsolete and worn out airplanes and engines to the Curtiss Aeroplane & Motor Corp. The contract was made following a request for bids from various airplane and engine makers, and Curtiss made the highest bid.

Practically every bit of this property, according to the War Department, is obsolete and worn out. The OX-5 engine is one of the 5-cylinder types of engine developing 90 hp., and was used in elementary training planes. They will have to be entirely rebuilt before they will be of any value. The JN-4 planes, which were also used in early training, can in some instances be overhauled and rebuilt, while the remainder, about 50 per cent, will be salvaged. These JN-4 planes are not the same as the JN-4-H planes now used by the Air Service, which are a much later model. The 1100 Standard planes have been condemned by the Air Service and are said to possess only scrap value.

The War Department will continue the policy of requesting bids from manufacturers of airplanes whenever necessary in order to dispose of certain surplus materials without disrupting the market.

—

Business Improving Steadily

DETROIT, April 7—All business here, especially in automotive lines, is showing a marked improvement. The transition to a peace basis is going forward with few serious jolts. Released available labor is being rapidly absorbed and building operations have taken a great boom. Work was started on 335 new buildings and 165 new additions during February. The majority of the building operations represent manufacturing plants and business places. The estimated cost of these new structures total $1,279,065.

Business is approximately 34.13 per cent normal as compared with 30 per cent in February. Business above normal during March was 17.64 per cent against 19.99 per cent in February. About 48.23 per cent is below normal, which is a decrease of 2 per cent when compared with February figures. Improvement totals 62.50 per cent, which is a big increase over the February record of 49.18 per cent. Only 8.75 per cent is on the decline, while 28.75 per cent is stationary.

—

Air Service Appropriations Cut 50 Per Cent

WASHINGTON, April 7—Appropriations for the Air Service have been reduced 51 per cent for 1918-19 from $944,304,758 to $459,304,758. The total appropriations for the service during the war, after making the reductions, total $1,097,304,758, of which 65 per cent, or $712,000,000, were expended to March 15.

It is estimated that $340,000,000 will be saved in the liquidation of suspended contracts. The following is a summary of the values of cancellations and suspensions of contracts to March 22, 1919:

	Value	Per Cent of Total
Engines and spare parts..	$266,961,771	54
Airplanes and spare parts	165,288,590	33
Chemicals and chemical plants	18,648,239	4
Instruments and accessories	10,761,081	2
Balloons and supplies....	10,071,035	2
Fabrics, lumber and metals	7,977,445	2
Miscellaneous	13,634,218	3
Total................	$493,342,379	

Speculation is Rife in Detroit

Wills and Leland Cars Talked Of —Maxwell-Chalmers and Saxon Affairs

DETROIT, April 4—Automobile business circles are awaiting with keen anticipation the outcome of a number of important matters this week, interest centering in General Motors, Saxon Corp. and Maxwell-Chalmers affairs. The trade is also discussing some pretty authentic rumors of a new car to be brought out soon by C. Harold Wills, formerly with the Ford Motor Co., and one of the designers of the Ford car. The labor situation and the veiled plans of the Lincoln Motor Car Co. are also causing much speculation.

The announcement of W. C. Durant relative to the $37,396,000 General Motors expansion plan, calling for the investment of $12,650,000 in new buildings, plants, additions, etc., in Detroit alone, created somewhat of a sensation, and has served to divert the attention of the automobile business from the tangled affairs of the Saxon Motor Corp. to some extent.

Detroit knows but little about the proposed Maxwell-Chalmers merger, which is said to be steered by the General Motors Corp., and which, if it materializes, will practically give General Motors control of the two companies. It is said General Motors will refinance the combination, taking over all of the common stock of the companies. William C. Durant and other General Motors heads have nothing to say regarding the plan at this time, and no information is being given out at Maxwell-Chalmers headquarters.

It is said, however, that Walter Flanders, president of the Maxwell Co., which is operating the Chalmers properties under a 5 year contract, is soon to resign from the company. It is added that he is disposing of all his Detroit properties and proposes to locate in Chicago. Mr. Flanders himself will not discuss the matter.

Those close to C. Harold Wills declare he is working on a new passenger car and is soon going to give the trade a sensation. Two cars are under construction, it is said. One of them is an experimental passenger car and another is a racer designed to make its debut in the coming Indianapolis races. This car is just about complete and will be entered under the name of a well-known racing enthusiast who will also enter two other powerful machines.

The Lincoln Motor Car Co., owned by Wilfred and Henry Leeland, is getting ready to enter the passenger car field. This company is building up its sales and advertising force, but details of the proposed car are being kept in the dark. It will be a 6-cylinder machine to sell at a popular price and will make its appearance in mid-summer, it is said.

There is quite a labor organization movement in Detroit. While labor was always strongly organized here, this spring is witnessing the birth of more union organizations than usual. The movement is spreading more rapidly in the factories themselves, where the different trades of individual plants are forming their own organizations. The machinists at Dodge Brothers, for instance, have their own organization now, and this same trade is also organizing in other plants.

The greatest movement, however, is the formation of the Automobile Workers' Union, designed to take all men and women engaged in any department of the automobile manufacturing business. This organization is growing rapidly and is conducting extensive membership campaigns.

There is also a movement on foot for a 6-hour working day. This movement is springing from an unknown source. The American Federation of Labor, which maintains headquarters in Detroit, knows little of the 6-hour question, and it is apparent that it is not being pushed by that organization. It is said that the 6-hour plan is being tested in several local factories, but an exhaustive inquiry fails to locate these factories. It is denied that 6-hour shifts are in operation at the Ford Motor Co., although rumors to that effect persist in gaining circulation.

—

France Has 220,000 Vehicles

PARIS, March 22—At the beginning of 1917 France possessed 98,534 privately owned automobiles exclusive of trucks, taxicabs, motorbuses and motorcycles. In 1914 the number of privately owned automobiles was 115,906. The decrease of 7372 is explained by requisitions made by the army, particularly during the first six months of the war. While the official figures show the number of automobiles in France to be 98,534, this is far from being the total. These returns are based on taxation. Cars which do not pay direct taxes are not included. Thus there is no official record covering the number of trucks, taxicabs, motorcycles, etc.

As the army possesses 95,000 automobiles, and as there are about 15,000 privately owned trucks in service and probably 5000 motorcycles, the total number of motor vehicles in France is about 220,000. The Department of France, which heads the list, is the Seine district, including Paris, where there are in service 15,818 privately owned automobiles. The lowest number is found in the High Alps Department, where there are only 74 automobiles.

—

Shipments to A. E. F. Decreased

WASHINGTON, April 7—A noticeable decrease in the shipments of engines and spare parts is displayed in figures made public to-day by the War Department, by which it is shown that 6 per cent of the tonnage of motors and spare parts were shipped in the first 20 days of March, 1919, as compared with 100 per cent of the tonnage shipped in October, 1918. Shipments of fuel, oils and

greases have likewise decreased. Following are the figures showing the tonnage shipments by months, as compared with the October shipments, estimating October at 100 per cent:

	Fuel, Oils and Greases	Engines and Spare Parts
November	171	99
December	159	49
January	132	9
February	148	12
March	113	6

Army to Have 1050 Tanks

WASHINGTON, April 7—Preliminary plans for the future United States Army provide for maintenance of a minimum of 1050 tanks, 330 to be of a heavy and 720 of a light type. Arrangements provide for 45 fighting tanks to a battalion, with 24 in reserve, and 45 to a light battalion, with 27 in reserve. The tanks which have already been manufactured and used, the 2-ton and the 35-ton, will be continued as the light and heavy types, the 35-ton being equipped with Liberty engines carrying a 37-millimeter cannon on each.

Lieutenant Vrooman Vindicated

WASHINGTON, April 5—Lieut. S. B. Vrooman, charged in the Hughes aircraft investigation report with violation of the statute prohibiting persons acting for the Government from tansacting business with a corporation in which they are interested, was vindicated of the charge yesterday by Attorney-General Palmer.

Testimony taken since the publication of the report, said the attorney-general's announcement, showed that all lumber for airplane propellers purchased by the Government from the S. B. Vrooman Co., Philadelphia, in which Lieutenant Vrooman was financially interested, was inspected by agents of the National Hardwood Lumber Association and not by the officer or others appointed by him. This information, the attorney-general held, constituted a complete vindication of the officer.

Liberty Airplane Engines Contracts Completed

WASHINGTON, April 7—All contracts for Liberty 12 engines were completed when the Packard Motor Car Co. made final deliveries on its contracts on March 21. A total of 20,478 engines were delivered to the Government by all the different companies from which they had been ordered, as follows:

Firm	Number Produced	Percent of Total
Packard Motor Car Co.	6,500	32
Lincoln Motor Co.	6,500	32
Ford Motor Co.	3,950	19
General Motors Co.	2,528	12
Nordyke-Marmon Co.	1,000	5
Totals	20,478	100

Restrictions on Ferromanganese Import Lifted

WASHINGTON, April 7—All restrictions on ferromanganese and spiegeleisen have been removed by the War Trade Board. Licenses will be issued freely.

Aircraft Production Board Dissolved

President Wilson Abolishes Bureau Formerly Headed by Howard Coffin

WASHINGTON, April 7—The Aircraft Production Board, of which Howard E. Coffin was chairman during the early part of the war, and about which centered the storm of "protests" from Congress, has been formally dissolved by President Wilson. A director of aircraft production will be appointed to work under Major General C. T. Menoher, in charge of production. Following is the complete executive order, signed Woodrow Wilson:

EXECUTIVE ORDER

By virtue of the authority in me vested as Commander in Chief of the Army, and by virtue of further authority upon me specifically conferred by "An Act authorizing the President to co-ordinate or consolidate executive bureaus, agencies and offices, and for other purposes, in the interest of economy and the more efficient concentration of the Government," approved May 20, 1918, I do hereby make and publish the following order:

I

The Aircraft Board, created by Act of Congress, approved October 1, 1917, having accomplished the important purposes for which it was created, is hereby dissolved.

The last paragraph of Section 3, Article 1, of the Executive Order of May 20, 1918, is hereby revoked and the following paragraph substituted therefor:

"A director of Aircraft Production, selected and designated by the Secretary of War, shall hereafter have direct charge, under the direction of the Director of Air Service, of the Bureau of Aircraft Production and he shall perform such duties in connection with the activities, personnel and properties of said Bureau as may, from time to time, be assigned him by the said Director of Air Service, or as may be prescribed by law."

II

All unexpended funds of appropriations heretofore made for the Signal Corps of the Army and already specifically allotted for use in connection with the functions of the Aviation Section of the Signal Corps and specifically placed under the jurisdiction of the Director of Military Aeronautics, as well as all such funds already specifically allotted for use in connection with the functions bestowed upon the Bureau of Aircraft Production and specifically placed under the jurisdiction of the Director of Aircraft Production are hereby transferred to and placed under the jurisdiction of the Director of Air Service for the purpose of meeting the obligations and expenditures authorized by law or Executive Order in the field of activity of the Aviation Section of the Signal Corps and the obligations and expenditures authorized by the Bureau of Aircraft Production.

Crow-Elkhart Personnel

ELKHART, IND., April 7—The personnel of the reorganized Crow-Elkhart Motor Co. is as follows: President, M. E. Crow; first vice-president, E. C. Crow; vice-president and general manager, M. E. Hoshaw; secretary, D. C. Thomas; treasurer, Henry Lichtig; vice-president and purchasing agent, H. B. Schmid. The officers, with S. H. Penfield, vice-president of the Salisbury Wheel & Axle Co., Peru Auto Parts Co. and Norwalk Auto Parts Co., and also identified with a number of other parts manufacturing concerns, comprises the board of directors. The St. Joseph Valley Bank of Elkhart has been appointed trustee for the note holders. The company expects to gradually build up the production to 15 cars a day within the next 60 days. Orders are booked at the present time for the first 60 days production.

Fordson Dealers' Convention

CHICAGO, April 8—The Rue Motor Co., Fordson representative in this territory, has formed a plan whereby dealers are to carry in stock a sufficiently large stock of parts to insure immediate replacements and, if necessary, will replace the entire tractor while the damaged one is being repaired. This was announced at the Fordson dealers' convention this week. More than 200 dealers attended the convention, which was addressed by A. E. Hildebrandt, president of the Tractor Distributers' Association of the United States, who spoke on power farming requirements. John Fletcher, vice-president of the Fort Dearborn National Bank, addressed the meeting on "Farming from the Bankers' Viewpoint."

Braddon Motors Company Gets Factory

CHICAGO, April 7—The Braddon Motors Co., a new concern involving Chicago capital, has been organized to build a small 4-cylinder car, and has secured a factory building at Downer's Grove, Ill. The moving spirit in the organization is George J. Fogle, vice-president and general sales manager, formerly with the Locomobile company and more recently with the Maibohm company at Milwaukee. Other officers are: President, F. J. Clark; secretary-treasurer, John Voiral. The company is capitalized at $50,000. Production at the rate of four cars per day will begin within the month. The car will be assembled from standard units, but painting and trimming will be done at the factory. The factory building is a two-story brick structure 50 x 100 ft.

Chair Factory Becomes Auto Body Plant

PORTLAND, MICH., April 5—The Ramsey-Alton Mfg. Co., which was a chair factory before the war, a wagon parts plant during the war, is now going to engage in the manufacture of bodies for motor trucks. The company has received its settlement on government contracts. Nearly $250,000 was spent in changing the plant from chair manufacture to war work. The company has not yet decided whether it will continue chair manufacture as an additional department or devote its entire time to the automotive business.

American Pressed Radiator Corp. Elects

DETROIT, April 5—The American Pressed Radiator Corp. has elected the following officers for the coming year: President, C. H. O. Meyer; vice-president, R. S. Drummond; secretary, John S. Irwin; treasurer, H. F. Hiney. Mr. Drummond was formerly vice-president and general manager of the Detroit Steel Products Co., and Mr. Hiney was associated with him at that plant.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Hayes Wheels for Trucks and Tractors

JACKSON, MICH., April 9—The Hayes Wheel Co., which has made wood wheels for passenger cars ever since the industry was established, is now launching into the business of supplying wheels for trucks and tractors, and has established a new branch in the plant of the Jackson Munitions Corp., which it has leased and will probably purchase. A large number of men are already employed in the munitions plant, and as fast as Government-owned machinery used for munitions work is removed by the Government machinery for making steel wheels and metal parts is being installed.

New Wilson Body Building Soon Ready

DETROIT, April 9—The new press and die department of the C. R. Wilson Body Co. will be completed within 60 days. This will add 200,000 sq. ft. to the company's plants. These additional facilities will enable the company to produce more than 1000 bodies per day.

Panzardi & Co. New Porto Rican Dealers

PONCE, P. R., April 9—Santiago A. Panzardi & Co. have been organized to buy and sell motor vehicles and accessories and will have the agencies for the following cars: White, Packard, Premier, Hudson Super-Six, Buick, Chevrolet and Essex, Indian motorcycles and Tilene greases. The firm is made up of Santiago A. Panzardi, Juan E. Villeta, Jaime Oppenheimer and Jorge Oppenheimer. Messrs. Villeta and J. Oppenheimer will have direct charge of the business, and besides the store here at Calle Isabel, corner of León, it will open agencies at Juana Diaz, Coamo, Barros, Santa Isabel, Adjuntos, Ponuelas, Guanica, Yauco and Guayanilla.

J. E. F. Spark Plug Putting Up Factory

MILWAUKEE, April 9—The J. E. F. Spark Plug Co. has completed plans for the erection and equipment of a plant at 37th Street and Hillside Lane. Work will begin at once on a one-story factory, 50 x 156 ft., of reinforced concrete and brick, designed to receive additions and extensions as necessary. The investment in building and equipment will be about $25,000.

Metal Products Sales Co. Organizes

DETROIT, April 9—The Metal Products Sales Co., formed by A. F. Stengle and F. B. Breakey, will act as direct factory representatives for the Globe Machine & Stamping Co., Cleveland; Standard Foundry Co., Buffalo; Springfield Malleable Iron Co., Springfield, O.; Enterprise Mfg. Co., Akron, O.; Maynard Electric Steel Casting Co., Milwaukee, and the Barnett Drop Forge Co., East Hampton, Mass.

Advance-Rumely $1,338,586 Ahead This Year

LA PORTE, IND., April 7—Showing net profits and income for the year of $1,188,928, as compared with $550,557 for 1917, the annual report of the Advance-Rumely Thresher for the year ended Dec. 31, 1918, reports a prosperous condition of the company. The gross profits from operations are $3,073,877, compared with $2,101,832 in 1917. Various items added to the above make a total profit and income for 1918 of $3,393,703. Net profits amount to $1,338,586, against $715,758 in 1917.

The report shows that during the year there was spent in La Porte for machinery, equipment and warehouses $237,332, and for similar purposes in Battle Creek $298,011. The plants here are running at practically capacity, while at Battle Creek the number of employees has been increased from 407 to 1415. The company subscribed for $2,000,000 in Liberty Bonds and purchased $366,320 for its employees, sold to them on instalment plan. It also bought $750,000 worth of U. S. certificates of indebtedness and $100,000 worth of Canadian Victory Bonds. During the year 376 of its employees entered military service. The debenture debt of the company was materially reduced. Reserves set aside amount to $876,065.

American Bosch Adds to Staff

SPRINGFIELD, MASS., April 7—Additions and changes have taken place in the staff of the American Bosch Magneto Corp. W. G. Brown has been transferred from the New York office to become branch manager of the Chicago branch. T. C. Miller, formerly assistant manager at Detroit, assumes the position of branch manager at New York. Harold A. Wilson, formerly of the Diamond State Fibre Co., has joined the organization as assistant branch manager at Chicago. A. C. Hyser, who was in charge of the service department of the Willard Storage Battery Co., goes to Detroit to succeed T. C. Miller, and Oliver S. Stanley, who has been the assistant manager of the St. George Paper Co., Norwalk, Conn., has become assistant manager at New York.

Glidden Co. Buys Pennsylvania Plant

CLEVELAND, April 5—The Glidden Co., manufacturer of paints, varnishes, acids and chemicals, has taken over the A. Wilhelm Co., Reading, Pa., and will continue the business as heretofore. Besides its factories in Cleveland, San Francisco and Toronto, it now has manufacturing facilities in the east.

Olds Up 40 Per Cent in Production

LANSING, April 9—Truck production at the Olds Motor Works is reaching quantity figures. Although this company went into truck manufacture only 2 months ago, that division of operation is now in full swing, 30 machines of the ¾-ton type being completed daily. Passenger car production is now at the 140 daily mark. This is an increase of 40 per cent over February figures.

Work on Olds Plant Expansion

LANSING, MICH, April 9—Work on one of the largest of the buildings to be included in the Olds Motor Works expansion program has begun on the Reliance Engine Co. property. This structure will be 700 x 240, and will be used to house the axle department of the plant. It is estimated that the expansion plans of the Olds company, which will be carried out this spring and summer, mean an expenditure of between $1,000,000 and $1,500,000. A new administration building is among the structures in prospect.

Ford Street Car Coming Next

DETROIT, April 4—Henry Ford and the engineers of his tractor organization are working on plans for a street car driven by an internal combustion engine, which will be demonstrated in Detroit this summer, according to Charles E. Sorensen, general manager of the Henry Ford & Son tractor plant.

Lieut.-Col. E. J. Hall, one of the designers of the Liberty engine, will come to Detroit to assist in the demonstration of the new car. He has already successfully worked out engine-driven street cars, but will co-operate with Mr. Ford in perfecting the latter's new idea.

Samson Plans 30 Tractors Daily

DETROIT, April 4—It is stated at the General Motors Corp. headquarters here that the Samson Tractor Co., Janesville, Wis., will begin operations in three weeks, and that by July 1 approximately 1850 Model M tractors will have been completed and shipped. It is expected that by that time the company will be producing 30 machines daily.

Hudson Doubles Car Production

DETROIT, April 5—The Hudson Motor Car Co. launched into its second quarter production Monday by doubling its output of both Hudson and Essex cars. From 2500 machines of each make last month this company jumps to 3750 production basis, and hopes to turn out 7500 jobs of both makes in April.

New Spring Factory for Standard Parts

CLEVELAND, April 7—A new spring factory is under construction for the Standard Parts Co. at Flint. It will replace the company's present Flint plant, long since outgrown. The new factory will have an immediate capacity four times greater than that of the old plant.

Men of the Industry

Changes in Personnel and Position

Barnes Gives Up Management of Parrett Tractor

CHICAGO, April 8—Claire L. Barnes has resigned as vice-president and general manager of the Parrett Tractor Co. He was instrumental in the reorganization of the company a year ago, and at that time took over the management of the company's affairs. Feeling that his work has now been completed, he has resigned to devote his time to the development of other interests. Mr. Barnes is a well known figure in the industry, having been for years associated with John N. Willys in the management of the Willys-Overland properties. Management of Parrett production will be under an executive committee of three under the chairmanship of President Dent Parrett, who recently retired from the service as a captain in the Ordnance Department.

—

LeRoy A. Hillman will be in charge of the branch of the Detroit Pressed Steel Co., which has been opened here for Disteel wheels. Mr. Hillman has been in civilian service with the Bureau of Aircraft Production, and before that operated The Bearings Shop, interest in which he still retains.

—

P. S. Russell, formerly general sales manager for the Hale & Kilburn Corp., Philadelphia, has recently been released from the army and has been appointed manager of the new Packard Motor Car Co.'s branch at St. Louis.

—

Harry M. Gardiner, General Motors Corp., has been appointed successor to H. J. Sproat, works manager of the Olds Motor Works, Lansing.

—

A. J. Wise, formerly with the F. B. Stearns Co., Cleveland, and later with the New York branch of the Paige-Detroit Motor Car Co., has been made manager of that organization.

—

Brockholst Mathewson has been placed in charge of the Detroit office of the Savage Arms Corp., which has recently been opened at 1408 Kresge Building.

—

Clifford A. Williams, director of sales of the Kissel Motor Car Co., Hartford, Wis., has resigned, to take effect April 15. He is to become vice-president of the Western Motor Co., new distributers of Kissel products in California and Arizona. This organization is headed by Cuyler Lee, former Packard distributer.

—

George Hills, manager of factory sales of the American Rolling Mill Co., has resigned to accept the general management of the Ohio General Tractor Co., Cleveland.

—

Wm. R. Blackburn, formerly factory manager of the Cadillac Motor Car Co., Detroit, has assumed the position of manager of the Gray Motor Co., Detroit. He was connected with the Cadillac company for twelve years.

Amel R. Carlson, who has completed his government service on the purchasing staff of the Wright-Martin Aircraft Corp., New Brunswick, N. J., has returned as assistant general manager to the Commonwealth Motors Co., Chicago.

—

Harold C. Bement has been placed in charge of the electric furnaces at the new plant of the Onondaga Steel Co., Inc., Eastwood, N. Y. He was formerly melter foreman at the government arsenal at Watertown, Mass.

—

M. W. Bartlett, for the past five years secretary of the Splitdorf Electrical Co., has joined the Wire Wheel Corp. of America as Eastern District representative, with headquarters in New York at 835 Eleventh Avenue. Service direction and export matters are also under his supervision.

—

J. D. Mooney, recently discharged from his military duties as captain with the 309th Ammunition Train, has gone with the General Motors Corp., New York. He was manager of the Hyatt Roller Bearing Co.'s Industrial Division prior to joining the army in 1917.

—

Clark W. Upp has been appointed special foreign representative of the Federal Motor Truck Co. to cover the West Indies, South and Central America and Mexico.

—

F. M. House, who has been with the Republic Motor Truck Co. for many years, has been appointed manager of the Pacific coast sales division of that company.

—

W. G. Langdon, who has been with the Willys-Overland Co. for some time, has been made assistant general purchasing agent of that company. He was formerly connected with the Michigan Stove Works and later with the Hayes Manufacturing Co.

—

W. L. Mahon, who has been with the General Motors Truck Co., Pontiac, for some time, has been made manager of a new department of the sales division of that company. He will have charge of research and statistics and will prepare data on motor truck operation for G. M. C. owners.

—

Paul Welhener, who comes to the motor truck field from the farm implement business, has joined the factory sales department of the General Motors Truck Co, Pontiac.

Yoder Becomes Secretary of Federal Trade Commission

WASHINGTON, April 5—J. P. Yoder, formerly special examiner of the Federal Trade Commission, has been made secretary of the commission to succeed Leonidas L. Bracken, who resigned recently. Mr. Yoder left the commission in February, 1918, to serve as a captain in the Army Sanitary Corps, and has recently returned from service in France.

—

S. Bloom has been appointed director of the Essenkay Products Co., Chicago. For the past year he has been in military service, and previous to that was in the advertising business both in America and Australia.

—

H. W. Meyer of the Ajax Auto & Aero Sheet Metal Co. has turned over his plant and machinery to the Ajax Auto & Aero Sheet Metal Co., Inc.

—

Milton W. Franklin, consulting electrical engineer, has been engaged by the Remy Electric Co., Anderson, Ind. Mr. Franklin has written articles for technical publications. He was formerly connected with the General Electric Co. and was president and general manager of the C. & C. Electric Mfg. Co., Garwood, N. J.

—

W. F. McLaughlin has been appointed factory superintendent of the Hyatt bearings division of the General Motors Corp. at Harrison, N. J.

—

C. P. Cary, who has been manager of the New England branch of the Garford Motor Truck Co. for several years, coming here from San Francisco, has resigned and is now in charge of the truck department of Alvan T. Fuller's agency for Packards.

—

George B. Chapman, who came to Boston from the Federal Truck Co., Detroit, to manage the agency placed by that company for New England, has resigned to succeed C. P. Cary as manager of the New England branch of the Garford Motor Truck Co. The position of manager of the Federal agency will be filled by C. E. Whitten, Jr., Lynn, whose father controls the Federal business in Boston and vicinity.

—

L. S. Chamberlain, formerly manager of the San Diego branch of the Savage Tire Corp., has been promoted to the position of assistant sales manager, with headquarters at the factory. H. E. Cressler, until recently with the Goodrich Tire & Rubber Co., succeeds him as branch manager.

—

Frank M. Comrie and **Wm. J. Cleary** have resigned from the Thielicke Advertising Co. to go into business for themselves as Comrie & Cleary, Inc., with offices at 1512 American Building, Chicago. Mr. Comrie is president of the new company, Mr. Cleary treasurer and general manager, and with E. J. Phillips and J. M. Rosser, constitute the board of directors.

Collision Abandonment Insurance Now Available

KANSAS CITY, April 9—A new kind of insurance, which provides payment by the insurance company of the unpaid notes held by dealers when a car or truck is damaged by collision and abandoned by its purchaser, is being written by the Employers Indemnity Corp.

This insurance is paid for by the purchaser when he buys the car, the charge being included among the other various items involved in arranging for the time sale. The dealer usually requires that the purchaser take out fire and theft insurance and some other coverages.

The new insurance protects the interests of the dealer (or of the banker or other person who may hold the notes). The policy costs $5 to $15, depending on the list price of the car. The purchaser has no interest in the indemnity. The policy explicitly guarantees to the dealer or holder of the notes that in case the car is damaged and abandoned the insurance company will take up the unpaid notes. The company is given possession of the car and takes its chances on salvage.

Decline in Malay Rubber Exports

WASHINGTON, April 9—Rubber exports from the Federated Malay States and Straits Settlements declined in 1918 to 140,631 tons as compared with shipments of 152,923 in 1917. This was due to the lack of cargo space and to the American restrictions on imports. Many of the rubber companies in Malaya voluntarily restricted their tapping operations, but notwithstanding there was a considerable amount of rubber stored at Singapore at the close of 1918. Following are the export figures for the past three years:

	Federated Malay States			Straits Settlements		
	1916 Tons	1917 Tons	1918 Tons	1916 Tons	1917 Tons	1918 Tons
Jan. ...	4,471	5,995	7,588	4,443	3,562	4,302
Feb. ...	5,207	7,250	6,820	3,359	6,495	2,334
Mar. ...	4,429	7,088	7,709	4,481	8,299	8.858
April ..	3,914	5,955	7,428	4,219	6,103	6,584
May ...	3,956	7,179	5,881	3,274	6,282	13,587
June ..	5,114	6,009	5,161	3,836	8,775	6,515
July ..	5,053	5,798	5,706	5,106	7,351	1,978
Aug. ..	5,782	6,487	5,291	3,246	8,786	1,249
Sept. ..	6,376	7,087	6,588	2,987	5,679	6,209
Oct. ...	5,968	7,079	5,901	5,233	4,702	3,260
Nov. ..	6,776	6,180	7,097	5,247	5,555	2,661
Dec. ...	5,718	7,724	7,085	3,219	6,503	4,889
Total	62,764	79,831	78,255	48,650	73,092	62,376

The Straits Settlements' totals include transshipments amounting to 7416 tons in 1917 and 4447 tons in 1918.

Goodrich-Lenhart Moves to New Factory

HAMBURG, PA., April 7—The general office of the Goodrich-Lenhart Mfg. Co. has been moved here, where the company has recently completed a new factory building. A sales office will be maintained in the Widener Building, Philadelphia, where it has been located for the past three years.

Chamber Recommends Repeal of Anti-Trust Law

WASHINGTON, April 4—Reconsideration by Congress of all anti-trust legislation is recommended by American industry as the result of a referendum vote of the business interests of the country represented in trade and commercial organizations, instituted by the Chamber of Commerce of the United States. Complete returns from the referendum, made public to-day, show that the constituent membership of the chamber voted in favor of all four proposals advanced by a special committee which has studied the subject.

The proposals and the vote follow:

Congress should be asked immediately to consider the present situation of all statutes constituting our anti-trust legislation—for, 1543; against, 51.

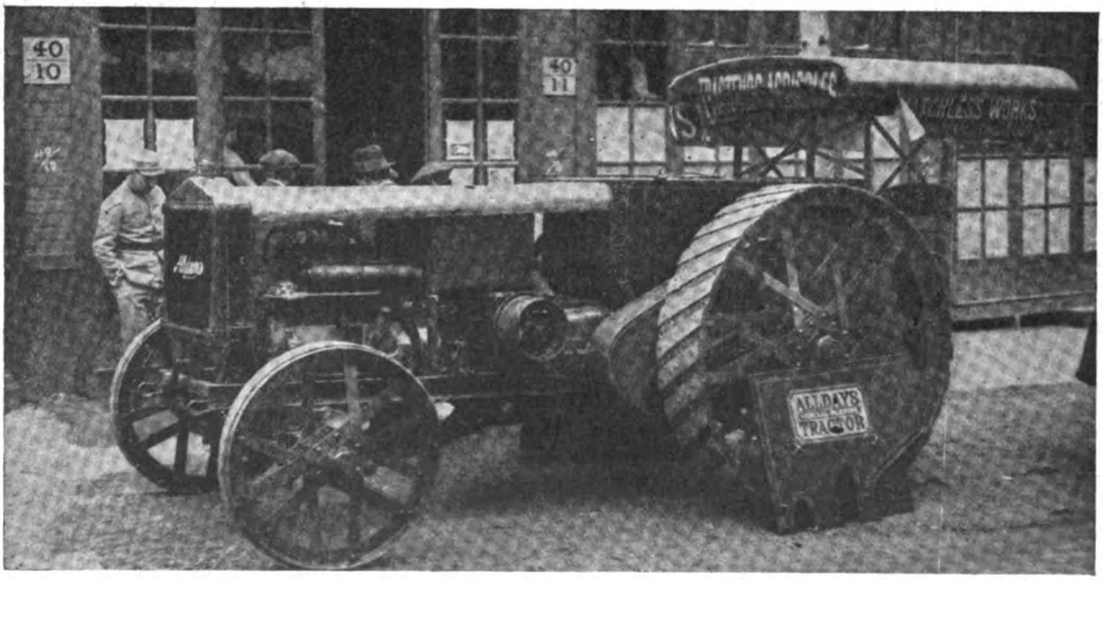
In reconsideration of existing anti-trust legislation there should be formulation of standards of general business conduct to be administered by a supervisory body—for, 1159; against, 389.

An enlarged Federal Trade Commission should be made the supervisory body—for, 1102; against, 437.

In view of the importance of the functions of the Trade Commission as they would exist the membership of the Federal Trade Commission should be increased to nine—for, 1104; against, 422.

The committee's report and the results of the vote are significant in view of the fact that the subject of anti-trust legislation will be taken up at the seventh annual meeting of the chamber to be held at St. Louis April 28 to May 1.

In requesting a vote on this legislation, the chamber pointed out that there were several hundred proceedings against great industrial concerns based on the Sherman act, and that frequent interpretations of the law had made it almost impossible for a manufacturer to know when he was violating it. It further pointed out the discouragement to business enterprise created by the act. Suggestion for the continuation and enlargement of the Federal Trade Commission was made because the commission has obtained a mass of information about American industry and commerce.



An English type of farm tractor exhibited at the Lyons Fair in France. It is the Alldays & Onions machine

Calendar

ENGINEERING SHOWS

April 5-12 — Bridgeton, N. J. Fourth Annual, Automobile Dealers' Assn.

April 5-12—Montreal, Can.—National Motor Show of Eastern Canada, Victoria Rink. T. C. Kirby, Manager.

CONVENTIONS

April 10-12—Philadelphia. National Assn. of Motor Truck Sales Mgrs., Bellevue-Stratford.

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

May 1-June 1 — Atlantic City, N. J.—Pan-American Aeronautic Convention and Exhibition — Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

Sept. 22-24—Philadelphia, Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

Foreign Trade Opportunities

WASHINGTON, April 7—The Bureau of Foreign and Domestic Commerce, Department of Commerce, has inquiries for the agencies of automobiles and accessories. Full information regarding each of the following can be secured by addressing the Bureau of Foreign and Domestic Commerce and referring to the Foreign Trade Opportunity number:

Italy — Agricultural machinery. Correspondence should be in Italian. No. 28899.

France—Heavy trucks. No. 28880.

Swedish buyer of harvesting and agricultural machinery is about to arrive in this country and desires to be placed in communication with American manufacturers and exporters. No. 28884.

France—Motor cars and accessories. Correspondence should be in French. No. 28907.

Norway—Electric touring cars (without tops), with chauffeur's seat in front, Edison batteries preferred; and rubber tires. No. 28910.

Algeria—Motor vehicles, to maintain a depot for same, and to secure an exclusive general agency for the sale in North Africa of automobiles, tractors, and other motor driven vehicles which might find ready sale in that country. It desires to establish a depot for these vehicles with all accessories, and requests catalogues and prices. No. 28912.

Scotland—Motor vehicles, principally 1-ton chassis, suitable for vans. No. 28923.

Switzerland—Industrial machinery. Correspondence should be in French. No. 28927.

Italy—Automobiles and accessories, including pneumatic tires, greases and oils for lubricating. Payment guaranteed through bank deposit. Correspondence should be in Italian. No. 28928.

Machinists Endorse Short Hours to Reduce Labor Surplus

COLUMBUS, April 9—Delegates to the convention of the Ohio Federation of Machinists have before them for consideration resolutions indorsing a 44-hour week and if necessary a 32-hour week to give employment to the 25,000 machinists said to be out of work because of the cancellation of government contracts.

To Popularize Magneto Ignition

NEW YORK, April 9—Five of the principal manufacturers of magnetos have banded together for the purpose of instituting a propaganda campaign to popularize the more extensive use of magnetos on various forms of automotive equipment. The association has established headquarters at 110 West Fortieth Street, New York. It includes Splitdorf Electrical Co., Newark; Bosch Magneto Co., Springfield, Mass.; Simms Magneto Co., East Orange; Eisemann Magneto Co., Brooklyn, N. Y.; Ericsson Mfg. Co., Buffalo.

Garage Association Formed

BOSTON, April 5—The Garage Association of Metropolitan Boston has been formed with a membership comprising active and associate members of more than 500. It plans to extend its activities throughout Massachusetts first and later all over New England.

Union Switch to Make Shafts

SWISSVALE, PA., April 5—The Union Switch & Signal Co. has purchased machinery for finishing crankshafts and camshafts, and will be ready for delivery about June 1. It manufactures its own forgings.

Singleton Advertising Co. New Name

CLEVELAND, April 5—The Singleton-Hunting Co., advertising agency, has changed its name to the Singleton Advertising Co. The management, personnel and financial status remain the same as before.

Dutch Rubber Activities Restricted

WASHINGTON, April 7—Rubber trade in the Dutch rubber market has not increased during the past year, according to the annual report of the Amsterdam Association for the Rubber Trade. No rubber whatever can be distributed to factories except under strict conditions imposed by the Netherlands Oversea Trust, which permitted distribution of only 464 tons during the past year. The report states that, contrary to expectations, the rubber trade will not be able to operate without restrictions despite cessation of hostilities. The shortage of cargo space will restrict the activities of the trade for a long period.

Greenfield's Second Show in Armory

GREENFIELD, MASS., April 7—Cars, trucks and tractors took part in the second motor show held here at the State Armory. As there were no miscellaneous accessory booths there was adequate room for the display of the vehicles. Dealers and distributers staged their own displays, which included the principal makes of motor vehicles of all kinds.

Elgin to Build Canadian Plant

WINNIPEG, MAN., April 7—The Elgin Motor Co. will build an assembling plant here to cost about $100,000.

Factories Urged to Adopt Open-Air Sports

DETROIT, April 5—The Recreation Commission will hold a conference for Detroit manufacturers Thursday, April 10, to organize plant welfare workers in promotion of inter-plant athletics and recreation. The big plants will be asked to form baseball clubs, tennis clubs and clubs for other athletic games.

Necessary Internal Co-operation

Between Employer and Employee

Must Be Mutually Evolved

Capital and Labor Are Equal Necessities in Modern Industry, Says Steinmetz, and Must Be Equally Represented in Management and Distribution of Profits

NEW YORK, April 11—Dr. Charles P. Steinmetz of the General Electric Co. expressed his views on the present chaos in the labor situation and the strife between capital and labor before the editors of New York business papers to-day by declaring that the necessary internal co-operation between the organizations and the workers will never come about until both parties mutually evolve the scheme. It will not do for the scheme to be evolved by the organization and thrust upon the workers, because then it will be viewed with more or less suspicion by the workers, and will be considered paternalistic to a greater or less extent.

Many organizations have advanced schemes for closer co-operation with their workers, but these have not been favorably accepted by the workers solely because they originated with the organization and the worker had nothing to do with the formulation of them. In all such cases the worker does not accept such suggestions favorably even if they might work for his good.

Internal co-operation that will be effective must come from the workers as well as the organization, and if a corporation has in mind evolving an improved scheme it is necessary for the workers to be given equal representation in the formulating and evolution of the plan. Such a plan, evolved under such conditions, will undoubtedly succeed if its fundamentals are correct, whereas such a plan evolved solely by the organization and thrust upon the workers would, in nine cases out of ten, not succeed.

Dr. Steinmetz believes that the organization must make greater sacrifices, make much greater expenditures of money and go immeasurably farther than it has gone up to this time in co-operation of labor in order to solve the present labor chaos. He advanced many reasons for this: Generally speaking, the organization heads are much better educated than the workers and so should be expected to take a broader view of the case. Many of the organization are college graduates, whereas too many of the workers have had to leave school at 14 and have had no opportunity of completing their education. It is really natural to expect that those who have had to neglect their education cannot take as broad a view of the situation as those who have had the opportunity of going through college. Because of this, the organization must take a broader view than it is inclined to take, and must view with greater clearness the radicalism, or, perhaps, unbusinesslike view, expressed by many of the workers.

The results leading up to the present division between capital and labor or between organizations and workers are historical, according to Dr. Steinmetz. It started when industry began growing and the factory owner could not keep in touch with his individual workers as he did at one time. This led to the appointment of superintendents, foremen, etc., whose acts ostracized workers to quite an extent. The employer got out of touch with his workers; he drifted away from them, his mind was engrossed in the development of business and the progress of the worker was neglected.

Inauguration of Labor Unions

This led to the creation of labor unions which were started for offensive purposes and literally became a hostile camp to the organization. It has taken a generation or more to bring about this condition of hostilities and it is not going to be corrected in a day, a week, a month or a year. And bringing about the desired internal co-operation is going to be a long slow process, in which the organization or employer must take the lead.

Dr. Steinmetz outlined the various systems that have been used by organizations to obtain closer co-operation, but dismissed most of them as being unsatisfactory, and advocated a plan in which capital and labor would have equal representation in each other—would be one group instead of two groups, namely, labor and capital. In his plan, labor would be equivalent to capital. The worker would have labor stock and the organization would have capital stock. Both organization and labor would share in the profits, getting dividends, one on capital stock and the other on labor stock. Both would share in the management; both capital and labor would be entitled to a fair rate of interest, capital on the money invested and labor on the wages for work done. All profits beyond this belong to capital and labor, and should be divided as dividends, part on the capital stock and part on the labor stock.

Dr. Steinmetz's address complete follows:

There is an old saying, "In unity lies strength and a house divided against itself must fall." If that is true of anything, it is true in Mother Industry, and particularly true to-day where modern civilization in the world's war has practically become bankrupt, and we now, as receivers, have to reorganize the world again. Our industries must have co-operation to be successful, efficient; to be able to take care of the world's work as it has to be done to redeem our civilization from what has occurred in the last few years. But is it possible?

Interests of Capital and Labor

The socialistic radical labor agitator tells us there can be no peace between capital and labor. They are inherently antagonistic and must fight to a finish because the interests of one are against the interests of the other. In industrial depression the employer as well as employed suffer. The old-time corporation president preaches to us that capital and labor interests are identical; that if the individual interests are trusted to his keeping that they will be taken care of. At the same time every child sees and knows that a dollar more paid out in wages means a dollar less profit and that the interests of capital and labor are different—entirely opposite in some respects. We cannot get any further in solving the problem if we take an extreme view one way or the other. Capital and labor interests are not identical but are the same in some respects and opposite in other respects. In general, in any industry, those interests which have to do with industry on the outside, customers, etc., are usually identical.

How to Institute Co-operation

Within the industry the interests of employer and employee are often opposite to each other. There are relations in which capital and labor interests are identical and some in which they are not identical, but there are many other relations in our modern civilization where there are common interests and unidentical interests. Take buyer and seller, manufacturer and customer, landowner and renter. Many interests in common, and still we do not have warfare. They are not going to fight merely because there are some features where the interests are opposite. In all those relations where the relations exist as between employer and employee, there is no settlement of the condition by fight and warfare; but on the contrary there are often, usually very often, friendly relations between the manufacturer and customer. It is not the historical relation, as we unfortunately find, in this one feature. Why is it necessary that employer and employees and capital and labor cannot get along in the same manner by co-operation? The reason is historical. Originally the employer and employee bore an equal standing as regarding industrial power in the days of small manufacture. The organization of employers as represented by the formation of industrial corporations meant an increased power on the side of the employer and a disadvantage to the employed, until labor organizations were formed; but conditions had already become hostile.

How to bring the co-operation about; how to return to such conditions as should have remained operative, is the main problem, because we must bring about co-operation within our industry if we wish to meet the demands of the new world.

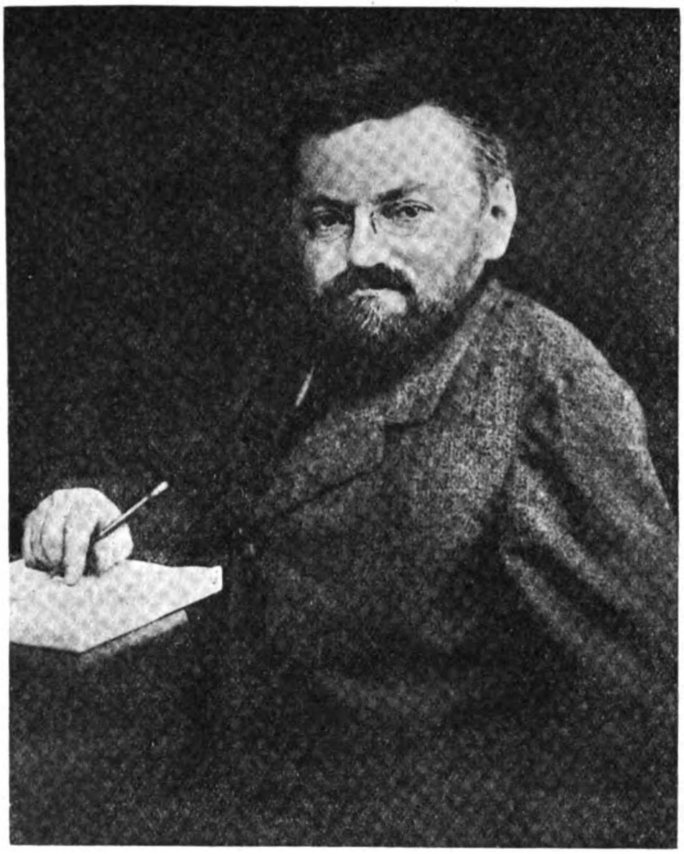
It has taken two generations of development to bring about the present unfortunate situation where differences are settled by fighting. We cannot expect to secure this co-operation by merely wishing or talking about it. It is a long, slow, difficult work which will mean many setbacks, and we have to remain at it and fight for it.

Employer Expected to Have Broader View

Adjustment must come first from the employers, but not from any moral reason. The present situation is not the fault of labor more than capital. It is merely historical development of a situation beyond the control of man. The employer must have a broader view than the employees. We must not forget that there are still many imperfections in our civilization. Most serious is that a large majority of men cannot enjoy complete education, as would be desirable for making the most of themselves, and heads of industry as a rule have the benefit of the broader education and must take the broader view of things. We cannot expect the same broad view of the one who left school at fourteen years of age as the one who has enjoyed a more extensive education. That the initiative must come from capital is realized. All through groups of occupations and industries we have talk on co-operation. We must realize it does not mean to spend a few dollars here and there, but the work is probably the most important development in the industrial field which faces us to-day, and men must devote their time and attention to it and must give high-grade service the same as those in charge of other administrations. We cannot expect to see any positive results until we are really willing to approach it more seriously in time, interest, quality of men and amounts of money devoted to bringing about industrial co-operation.

Co-operation implies two parties working together, not one settling the matter and telling the other you must do that and that and then we will co-operate. Unfortunately, most of the serious efforts made in this direction have been of that character—that the employer has worked out plans and then asked the employees to co-operate on those plans. Very often those plans are good and the whole scheme would have been satisfactory if it could have been worked out jointly, but it came as paternalism and was therefore tainted from the beginning. That is not co-operation.

It is easy to say we must have co-operation; also to find fault. It is not easy to make suggestions how it should be done and how the present strained relations between capital and labor should be overcome. Probably there is no single way to bring about true co-operation. It depends largely on local conditions and social conditions. In short, there is not a broad and single way. Before we try to find out let us discover the relation of Mother Industry. One attitude, the attitude of the old-time employer, which means industry is private property of the one who supplies the capital. That is the old-time relation where industry is private property of the owner, which recognizes only capital and not labor. This relation was destroyed forever at the moment when President Roosevelt interfered in the anthracite coal trouble and brought both sides to terms. The other extreme is the socialistic conception that all wealth is created by labor and that all wealth therefore belongs to labor and that capital is a parasite on labor due to having acquired a monopoly of the means of production. At present industrial production requires capital and labor. Both are necessary. Labor unrest is a demand for a share of the profits of industry and a share in the management of industry. This is the final foundation of all our social unrest. Since they are both necessary it is right that they both demand a right in the share of the profits and management of industry. There are several ways—mostly unsuccessful. One way, welfare work, which is important and useful but offensive and insulting, by being forced on labor in a paternalistic manner. It is appreciated where not done as a welfare work but merely as a matter of corporate self interest. We must realize quality of one's work depends on conditions under which work is done. That makes the difference in the self-respect and quality of the man. This will not bring about co-operation. We must not use the name welfare work. It should be called an Industrial Relation Department or Committee, instead of Welfare Department. The most difficult thing in co-operation is to put yourself in the other's place and see things as he sees them.



DR. CHARLES PROTEUS STEINMETZ was born in Silesia and educated in Berlin and Zurich. He came to America more than 30 years ago and is at present chief consulting engineer for the General Electric Co., Schenectady. When Steinmetz reached America he had just $10 in his pocket. He is physically handicapped as very few men are, and yet has risen by sheer force of will and intellect to a commanding position as a worker and a thinker. He has written many books on various subjects and is considered by many to be the greatest electrical engineering genius in the world.

Another attempt which has been made is the attempt of getting closer relation by the bonus system, giving bonuses during times of industrial prosperity and getting the employee interested in the industry. To some extent that is all right. Somewhat of paternalism. It may be all right in Germany, where people have been trained to look up to their masters as superiors, but leaves a bad taste among Americans. They are prone to ask, "Why not give us an increase of wages instead of a bonus?" The bonus system has the disadvantage of sharing only in profit, not in management.

Another attempt is the committee system, claimed to have been successful in England. There are several forms. There are the committees elected by employees which take up with employers all relations of mutual importance and interest, arbitrating wages, hours, etc. Another form is joint committee, half of which is elected by employees and half by the corporation. This appears to have very much in its favor. There are, however, some difficulties. The most serious difficulty is that labor has its own organization, and such action is apt to be taken by labor unions as not recognizing them. Labor unions claim that they represent the employees. Facts show in many cases that they are right, because while union men may often have a minority among employees, when serious questions arise, experience very often shows that the majority of non-union workers take the lead of the union rather than the non-union committees. Shop committees are liable to be considered as eliminating the labor unions by putting up a rival union. While leaders of industry recognize the necessity of co-operation, unions of labor organizations have not yet realized the advisability of co-operation in industry. But there is another side. Do we want the committee system? Let us assume it is successful. A board of directors on one side and a labor committee or committees on the other. Is this not another warfare by organizing two different parties? The last is wage dividend. Mother Industry requires capital and labor. Therefore both are entitled to share in the profits. Capital is entitled to a fair rate of interest on the money invested and labor is entitled to a fair rate of wages for the work done. All profits beyond that belong to capital and labor. These should be divided as dividends, being dividends on capital stock, the other being divided on labor stock as found by yearly wages. This system is in operation in a number of corporations, in electric utilities companies and others. It lacks provision for share in the management. But we could carry it further and recognize labor as equivalent to capital and give the labor stockholder the same right as the capital stockholder in the management. This would be revolutionary, but both would share in the profits, getting dividends, one on capital and the other by labor stock. Both share in the management (labor union officials could hold the proxies). This does not set up rival administration, but brings about joint control by evolution and not by revolution. The question is: How far should employees be recognized as stockholders? Should every one, even if he joined yesterday, vote to-day? There are many things that show that only those who have been with the organization for a number of years should be recognized as wage stockholders, taking part in dividends and management. We could set the limit at ten years. There would not be many and would not make any radical change in industry, and every year or so we could change the minimum, going down to six or five years. This would eliminate any opposition except from the extreme socialists who refuse to recognize capital at all.

Finally, leave only laboring men as stockholders. This revolution could be brought about by evolution if desired. This could be carried to full socialization of society by evolution, as the final outcome of our industrial development.

Gear Makers Hold Successful Meeting

Company Representation in American Gear Manufacturers' Association Doubled Within a Year—Progress Made in Standardization Work—Technical Papers Read and Discussed

By P. M. Heldt

WORK on its standardization program and the reading of technical papers filled most of the 3 days' session of the American Gear Manufacturers' Convention held at the Hotel Statler in Cleveland on April 14, 15 and 16. The Association is a rapidly growing one, as is shown by the fact that while at the time of the meeting at White Sulphur Springs, W. Va., last year there were only 32 member companies, the number had increased to 59 at the time this meeting was called, and several more were added in the course of the meeting. As President Sinram expressed it in his inaugural address, most of the manufacturers of cut gears are now represented in the Association.

The present meeting brought the Association to the close of its second year. In his inaugural address President Sinram said that the third year of the Association's activities opened with our country and business confronted with many large problems, and that few would question the statement that the future would demand radical changes in many directions. In the evolution already under way, co-operation would light the way to many of the problems arising. The character and extent of this co-operation would measure the influence of the American Gear Manufacturers' Association and would have a distinct bearing on the stability of the industry.

President Sinram's Address

Mr. Sinram quoted Otto Kahn, the eminent New York banker, who, in a recent address before the Cleveland Chamber of Commerce, stated that the United States was facing the greatest era of prosperity in its history, and, farther, that this country would stand fast no matter what happened in Europe. Nearly a year ago, at the White Sulphur Springs meeting, in speaking of the Gear Makers' Association, he had made the statement that "The foundation had been completed and was substantial." Notwithstanding the unprecedented demands upon industry during the interval, the American Gear Manufacturers' Association had made progress.

Membership in the A. G. M. A. had become a valuable asset to the gear manufacturer. The second year of the Association closed with over 60 interests privileged to use its monogram, these being represented by more than 120 leaders of the art. Few were the representative manufacturers of cut gear who were not affiliated with the A. G. M. A. This membership evidenced a desire and willingness to co-operate, and an appreciation of the value of the exchange of ideas on subjects of common interest.

Referring to the subject of standardization, Mr. Sinram said the evolution of gear standards was an obligation the gear makers owed not only to themselves, but to the collective gear purchasers and the enginering world. While gear standardization in the aggregate was a task of considerable magnitude, a start with the simpler phases would form the foundation on which they might build successfully. Definite and specific standards would be recommended for the consideration of the Association in the near future.

Demands of the war and other conditions had restricted progress during a part of the year just closing. However, a most successful meeting solely in the interests of standardization was held in Buffalo in February. Another meeting was held at Buffalo on March 27 by the Commercial Standardization Committee, and as a result definite and specific recommendations would be submitted for consideration to the Association.

Some consideration had been given to the formation of a division or bureau to adjust controversies as to product between manufacturer and purchaser—a plan to insure equitable settlement without litigation. Times and conditions considered, the A. G. M. A. was to be congratulated on its progress and the present state of the organization. A successful industrial organization had been developed under most abnormal conditions and was now available for service. To be of greatest benefit to the membership now demanded activity in practically every phase of Association endeavor, and the success of the A. G. M. A. was the responsibility of every representative.

Standards Committee Meeting

After the official welcome to Cleveland by a representative of Mayor Davis and the reading of President Sinram's inaugural address, the meeting was turned over to Chairman F. B. Waterman of the Standards Committee. The entire afternoon of the first day was devoted to reports of various subcommittees of the Standards Committee and discussions thereon. Reports were made by the following sub-committees: Spur Gear, Bevel and Spiral Bevel Gearing, Worm, Worm and Spiral Gears, Herringbone Gears, Sprockets, Composite Gearing, Gears and Pinions for Electric Railways and Mine Locomotives, Hardening and Heat Treating, Inspection.

None of the work of the sub-committees was in such shape that final action could be taken on it, and the recommendations definitely adopted as standards at this meeting of the Association. Hence it is not considered advisable to go into the details of the reports and discussions.

The greatest progress had been made by the Commercial Standardization Committee, which had worked out a blank contract form which it is expected the Association will definitely adopt immediately.

This will form the basis of any contract entered into for the manufacture of cut gears by members of the Association, and covers all the points that come up in doing such work.

Technical Session

What may be described as a technical session of the meeting took place Tuesday forenoon, when three papers on subjects of interest to gear makers were read. The first paper on "Gear Steels," was by Dr. J. Heber Parker of the Carpenter Steel Company. We expect to reprint this paper in full in an early issue of AUTOMOTIVE INDUSTRIES. Mr. Parker said that cut gears might be conveniently divided into three classes, namely, gears for automotive, electric car and commercial or jobbing use, respectively. They might also be divided into two classes according to the grade of steel used and the kind of heat treatment given it, into case hardened and tempered gears.

The question had often been asked as to which of these two classes was the better, but the only answer that could be given was that each was best adapted to a particular class of work. Tempered steel gears were best for clash gears, while case-hardened gears were best for constant mesh gears. With tempered gears, misalignment of shafts was sometimes a cause of pitting. This could be overcome by a change in the drawing temperature and sometimes by an increase in the length of gear face.

Dr. Parker said that there were in use six grades of steel

for automotive gears, and he gave a table showing the chemical compositions and the physical properties of these steels. It is of interest to note in this connection that the elastic lin.it of the core material of case-hardened gears made from these steels varies from 50,000 to 150,000 lb. per sq. in.

Discussion of Dr. Parker's Paper

This paper was followed by a lively discussion. E. J. Frost asked the speaker whether he had made any experiments to determine what percentage of phosphorus and sulphur was necessary to produce any harmful effect on the properties of steel. Dr. Parker said that the impression that phosphorus and sulphur were very detrimental constituents had been handed down from the dark ages. During the war the Standardization Committees of the Society of Automotive Engineers and the American Society for Testing Materials had let down the bars on phosphorus and sulphur to a large extent, simply because it was impossible to obtain steel in the large quantities required under the rigid specifications as to these two elements which had previously been insisted upon.

Dr. Unger of the Carnegie Steel Co. had made some tests with high sulphur steels in which the excess sulphur was added to the steel in the mold, and his results showed that an excessive sulphur content had no deleterious effect, but this method of adding the sulphur had been objected to by some of his colleagues.

Dr. Parker said that the greatest value of a low sulphur in steel was really the fact that it was a criterion of the conditions under which the steel had been produced, because sulphur could be eliminated only by means of a reducing slag, and the fact that there was a low sulphur content therefore showed that the steel had been made in a reducing atmosphere. In order to show the real effect of sulphur on the physical properties of steel, it would be necessary to run a big open-hearth heat, and that of course would be an expensive undertaking.

A question was also asked as to whether there was not a tendency toward non-uniformity in the quality of 3½ per cent nickel steel. Dr. Parker said that this steel had a tendency to laminate, and as a result showed low values in transverse tests. The addition of a moderate amount of chromium overcame this tendency.

Dr. Parker also made repeated references in his paper to the subject of shock tests and drop tests. This matter was also referred to in the discussion and it was then brought out that it was almost impossible to make a comparison of the results of such tests obtained by different observers, owing to the use of different machines and to different conditions in making the tests. The suggestion was made in this connection that the American Gear Manufacturers' Association might take it upon itself to standardize a shock test and a shock testing machine for gear material.

Value of Vanadium Steel

A question was also asked the speaker in regard to the value of vanadium steel. His answer was that his company did not believe in the use of steels containing minute quantities of vanadium, of the order of 0.08 per cent. Vanadium steels had been exploited by the sellers of ferro-vanadium. The point had been made that the vanadium steels had better machining qualities than chrome nickel, and other high-grade steels, but here they ran up against the difficulty that there was no recognized test for machinability. Steels containing an appreciable vanadium content were of very high quality, but with vanadium climbing rapidly back to its old price of $10 per lb. the outlook for the popularization of these steels was rather discouraging.

Dr. Parker was also asked regarding the respective merits of the scleroscope and the Brinell machine for testing hardness. He said that one advantage of the scleroscope over the Brinell was that it could be used on any finished surface without destroying that surface. A scleroscope no doubt could be used very well for inspection purposes. That is, after it had once been decided that a material should show a certain scleroscope hardness, the instrument was well adapted for quickly determining whether or not the parts were up to this degree of hardness. But where it was decided to make comparative tests the Brinell instrument was preferable at least up to about 400 points.

Reference was also made in the paper to air-hardening chrome nickel steels, and in answer to a question the speaker said that these were introduced by Derihon of Belgium, and only a small amount found its way to this country previous to the war. This steel contained 0.30 per cent of carbon, 1.5 per cent of chromium and 4 per cent of nickel, and its most valuable characteristic was that it hardened in the air without practically any distortion.

The usual plan was to place the parts on an iron plate which was inserted into the furnace and heated up to a moderately high temperature, after which the plate was withdrawn and the parts allowed to cool in the air. A scleroscope hardness of 70 is about the limit obtainable with this steel. Unfortunately this steel is very hard to machine, and another difficulty is that it must be annealed within very narrow temperature limits. Where it is essential to have a hard surface without distortion this steel has its uses. During the war it was employed for the connecting rods of aircraft engines.

In order to obviate difficulty from distortion, some people in manufacturing case-hardened gears first rough them out, carbonize and quench them. Then the gears are annealed, finish-cut and rehardened.

Worms and Worm Wheels

The next paper on the program was one on "Worms and Worm Wheels," by G. W. Carlson of the Timken-Detroit Axle Co. and was of an elementatry character. Mr. Carlson brought out the fact that in the early years worm gearing was used chiefly to effect a very large reduction in speed; this necessitated very short leads and resulted in a low efficiency of transmission. People had formed an idea that whereas in spur and bevel gears the motion was very largely of a rolling character and there was only a slight amount of sliding motion, in worm gearing the motion was almost entirely sliding.

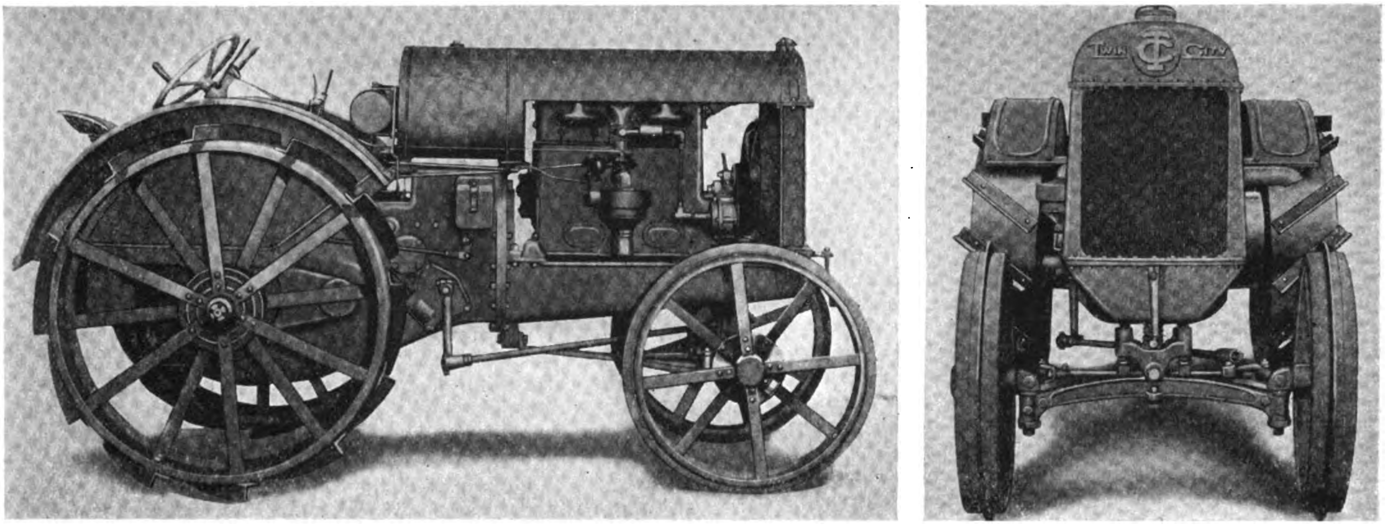
However, recent advances in the design of worm gearing had resulted in an increase of rolling and a decrease in sliding motion. Asked as to how this had been brought about, Mr. Carlson said by the adoption of a constant lead angle of 45 deg. and a pressure angle of 45 deg. taken on a line tangent to the tooth base circle of the wheel.

Mr. Carlson was asked whether the chief object in view in the selection of this large pressure angle was not to secure more space to get a grinding wheel in between the teeth, to which query he replied that the design of the gear had been perfected in England by the David Brown Co., and that he was not in position to give the reasons for the choice of pressure angle.

J. B. Foote gave some points regarding the use of worm gearing in tractor drives. He said there was a great difference in the conditions of operation of the final drive gears in motor trucks and motor tractors respectively. In plowing with a tractor the machine pulls under nearly full load sometimes for a distance of three-quarters of a mile or so without letup, and under these conditions the oil film is forced out from between the teeth, with the result that the draft is as much as 25 per cent greater when approaching the end of the field as when first beginning the furrow. Naturally, there is also a great deal of wear on the gear. Therefore, in designing a tractor worm gear the aim should be to make it large enough to prevent the forcing out of the oil film, but if this is done there will not be sufficient ground clearance. He was, therefore, of the opinion that the worm gear was not as well adapted to tractor transmission as to truck transmission.

E. J. Frost read a paper on "Proper Sizes and Materials for Gears for Tractor Construction." We expect to reprint this paper in full in an early issue of AUTOMOTIVE INDUSTRIES. The main point of Mr. Frost's argument was that by the use of high-grade alloy steels in tractor construction the necessary sizes of gears and shafts could be much reduced and thus the proper enclosure of the working parts greatly facilitated.

The entertainment features of the convention, in charge of J. C. McQuiston of Pittsburgh, were also a great success. They included a banquet at the Statler and an automobile tour through the city of Cleveland.



Side and front views of the new Twin City tractor

Twin City 12-20 Kerosene Tractor

A Three Plow Tractor with Double Intake and Exhaust Valves, Enclosed Drive, Pressure Lubrication, Thermostatic Temperature Control, Backbone Frame Construction and Front Spring Suspension

By P. M. Heldt

NONE of the new tractors put out during the past year has elicited more favorable comment than the Twin City 12-20 which was introduced to the trade at the New York and Kansas City shows. It is the product of the Minneapolis Steel & Machinery Co., and is built from designs of two well-known members of the S. A. E.: H. C. Buffington, who is responsible for the engine, and A. W. Scarratt, the company's tractor engineer. Some of the advanced features embodied in the design are removable cylinder liners, counterbalanced crankshaft, double inlet and exhaust valves in the cylinder head, thermostatic engine temperature control, completely enclosed drive, backbone frame construction and spring suspension in front. The machine is to be turned out on a quantity basis at a moderate price, and there is little doubt that it will be a strong factor in the tractor market.

The cylinder bore is 4¼ in. and the stroke 6 in. The rating of 20 hp. on the belt is very conservative, as a maximum of 35 hp. is developed on kerosene and 40 hp. on gasoline at the governed speed of 1000 r.p.m. With gasoline, a brake mean effective pressure of 93 lb. per square inch is thus obtained, and with kerosene about 82 lb. These figures are considerably above the pressures obtained from conventional tractor engines, and reflect the favorable influence of the double valves and the rational form of combustion chamber.

The cylinders, together with the upper half of the crankcase, are cast in a single block, into which are inserted the cylinder liners. These liners form the entire cylinder wall, and have a bearing or guide at both ends. At the lower end a groove is turned in the guide, which is filled with packing material, while at the upper end the liner is formed with a flange, which is fitted to a ground seat. The lower end of the liner is tapered both inside and outside, so that it can be readily inserted into the cylinder block and the pistons and their rings can be easily introduced into the cylinders from the lower end. The cylinder head is cast separately, and this permits of seating the valves directly on the metal of the head and thoroughly water-cooling both the valve seats and the valve stems.

The bottom half of the crankcase is made of sheet metal, and two dash plates containing the splash troughs are inserted into the base. The crankshaft is 2⅜ in. in diameter, and is carried in three main bearings, all supported from the upper half of the case. Balance weights are forged integral with the four short arms of the crankshaft. The connecting-rod bearings measure 2⅝ x 2⅞ in., and the dimensions of the main bearings are as follows (front to rear): 2¼ x 3 1/16 in., 2 11/16 x 2⅝ in., and 2¾ x 4 in. The camshafts also are supported in three bearings each, and are so arranged that they can be withdrawn from the forward end of the engine. The shafts are 1¼ in. in diameter, and the three bearings are of the following dimensions (front to rear): 1⅞ x 2¼ in., 1⅞ x 2¼ in., and 1¼ x 2¼ in. These camshafts run in bronze bushed bearings, and have the driving gear bolted to an integral flange at the forward end.

The valves are arranged in the head at the corners of a square, the two on one side of the engine being the inlet valves, and the other two the exhausts. They have a clear diameter of 1½ in.

It will be seen from the cross-sectional drawing of the engine that the piston, when in the topmost position, projects slightly above the cylinder liners, and the entire compression space is within the cylinder head casting. This obviates the necessity for counterboring the liner from the top end. Pistons are made of cast iron, and are of conventional design, with three ¼-in. compression rings at the top end and an oil scraper ring at the bottom end. They are 5 in. long, and it will be observed that the bearing surface is about equally divided

between the upper and lower ends. The piston pin is secured in one of the piston bosses by means of a pin screw, which is secured in position by a lock nut and a cotter pin, the latter inside the piston pin. There is nothing special to note in regard to the construction of the connecting-rod, except that the cap is held on by four bolts and that it is provided with a substantial oil splasher.

The valves are operated through the intermediary of rockers and tappet rods. These tappet rods are formed with ball ends at top and bottom, the bottom end resting in a suitable socket in the bottom of a thimble-shaped push rod, which bears directly on the cam, thus forming a mushroom type cam follower. Similarly, the top end fits in a socket formed in a headed pin set into the end of the rocker lever. The valve guides have inserted bushings, and the rocker arms are provided with set screws for the purpose of adjusting the clearance. Each pair of like valves in a cylinder is operated through a single tappet rod, but each valve is separately adjustable. The valve rockers are mounted on a hollow shaft, which can be oiled through oilers on top of the pressed-steel valve housing, so that it is not necessary to remove this housing when it is desired to oil the valve mechanism. The shaft is carried in bearing brackets bolted to the cylinder heads. Oil tubes are screwed into the tops of these bearing brackets and project through the valve cover. The valve cover is formed with an outward flange where it joins to the cylinder head, and is held in position by means of nuts on the oil tubes. There is communication between the valve chamber on top of the cylinder and the crank chamber, and the crankcase breather is located on top of the valve cover. This places the breather in a high position, where there is likely to be less dust in the air. It also tends to carry some of the oil mist from the crankcase up into the valve chamber, and thus keep all parts lubricated. Contrary to common practice, the breather does not also serve as an oil filler, a special filler being secured to the forward one of two hand hole cover plates on the right side of the crankcase.

The cylinder block is cast with two compartments on each side, through which the tappet rods pass. These are open at top and bottom, but there is no opening in the outside wall, hence the usual valve cover plates are missing. Owing to the absence of these covers, and the fact that the cylinder block is straight from top to bottom, without the usual break at the bottom of the water jacket, and merges gradually into the crankcase, the engine is of unusually clean-cut appearance.

The engine is equipped with a Holley 1¼-in. kerosene carbureter. The latter draws air through a dry-type air cleaner, and fuel is fed to it by gravity from a tank having a capacity of 23 gal. of kerosene. There is also a gasoline tank of 3 gal. capacity, gasoline being used for starting. The location of the two fuel tanks is clearly shown in the side view of the complete tractor, the main tank, which is of cylindrical section, being placed on a saddle over the forward part of the transmission, and the small tank being secured to the rear side of the large one. The main fuel tank forms the rear support of the engine hood. The Bennett air cleaner is located directly beneath the carbureter, on the right-hand side of the engine. A Pierce centrifugal governor is used, and is located close to the carbureter, acting on a separate throttle in an insert in the inlet pipe.

Ignition is by a Bosch high-tension magneto, with impulse starter. The magneto is located on the left side of the engine, toward the rear, and is driven through the pump shaft, which in turn is driven through a flexible joint from a gear meshing with the exhaust camshaft gear. The governor, which is set to control the speed of the engine at 1000 r.p.m., is completely enclosed and sealed. Provision is made for fitting a speed indicator which will show the operator whether the engine is working properly, and when it is overloaded. This is not a part of the regular equipment, but is furnished at an extra charge. S. A. E. ⅞-in. spark plugs are used, and are screwed into the cylinder head casting from the side.

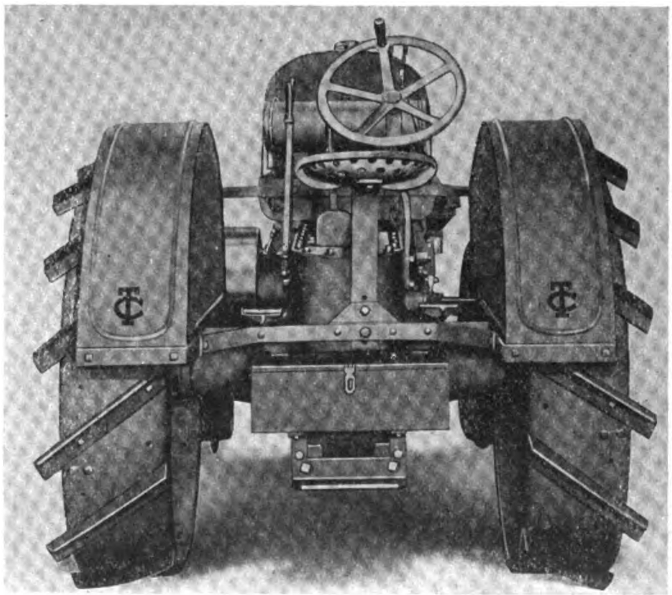
A Spirex radiator, with cast-iron top and bottom tanks and side spacers, is fitted. Water is circulated through it by means of a centrifugal pump, the outlet flange of which bolts directly against the engine casting. A 4-blade 20-in. fan is mounted on the engine, back of the radiator, and is driven through a 2-in. flat belt, the tension of the belt being maintained automatically by a coil spring pulling on the long arm of the bell crank bracket supporting the fan. The outlet from the cylinder jacket is at the forward end, and it is within this outlet fitting that the Sylphon thermostat is located. The entire cooling system has a capacity of 7 gal.

Lubrication of the crankshaft is by force feed. The gear-type oil pump is secured to the outside of the gear housing, being driven from the forward end of the pump and magneto drive shaft, and draws oil from the bottom of the crankcase through an outside pipe. It delivers oil into a main distributer pipe in the side wall of the crankcase, from which there are branches to each of the three main bearings. There is an automatic relief on the oil pump, which prevents the oil pressure exceeding a certain value. Oil holes are drilled in the crankshaft from the main to the connecting-rod bearings, and lubrication of the cylinder and piston-pin bearings is effected by both spray and splash. The large oil pockets forward on the camshaft bearings deserve notice.

The engine is mounted as a separate unit upon a front frame casting which bolts up to a bell housing on the forward end of the transmission case, thus insuring perfect alignment of the engine and transmission units. The bottom tank of the radiator forms part of the frame casting.

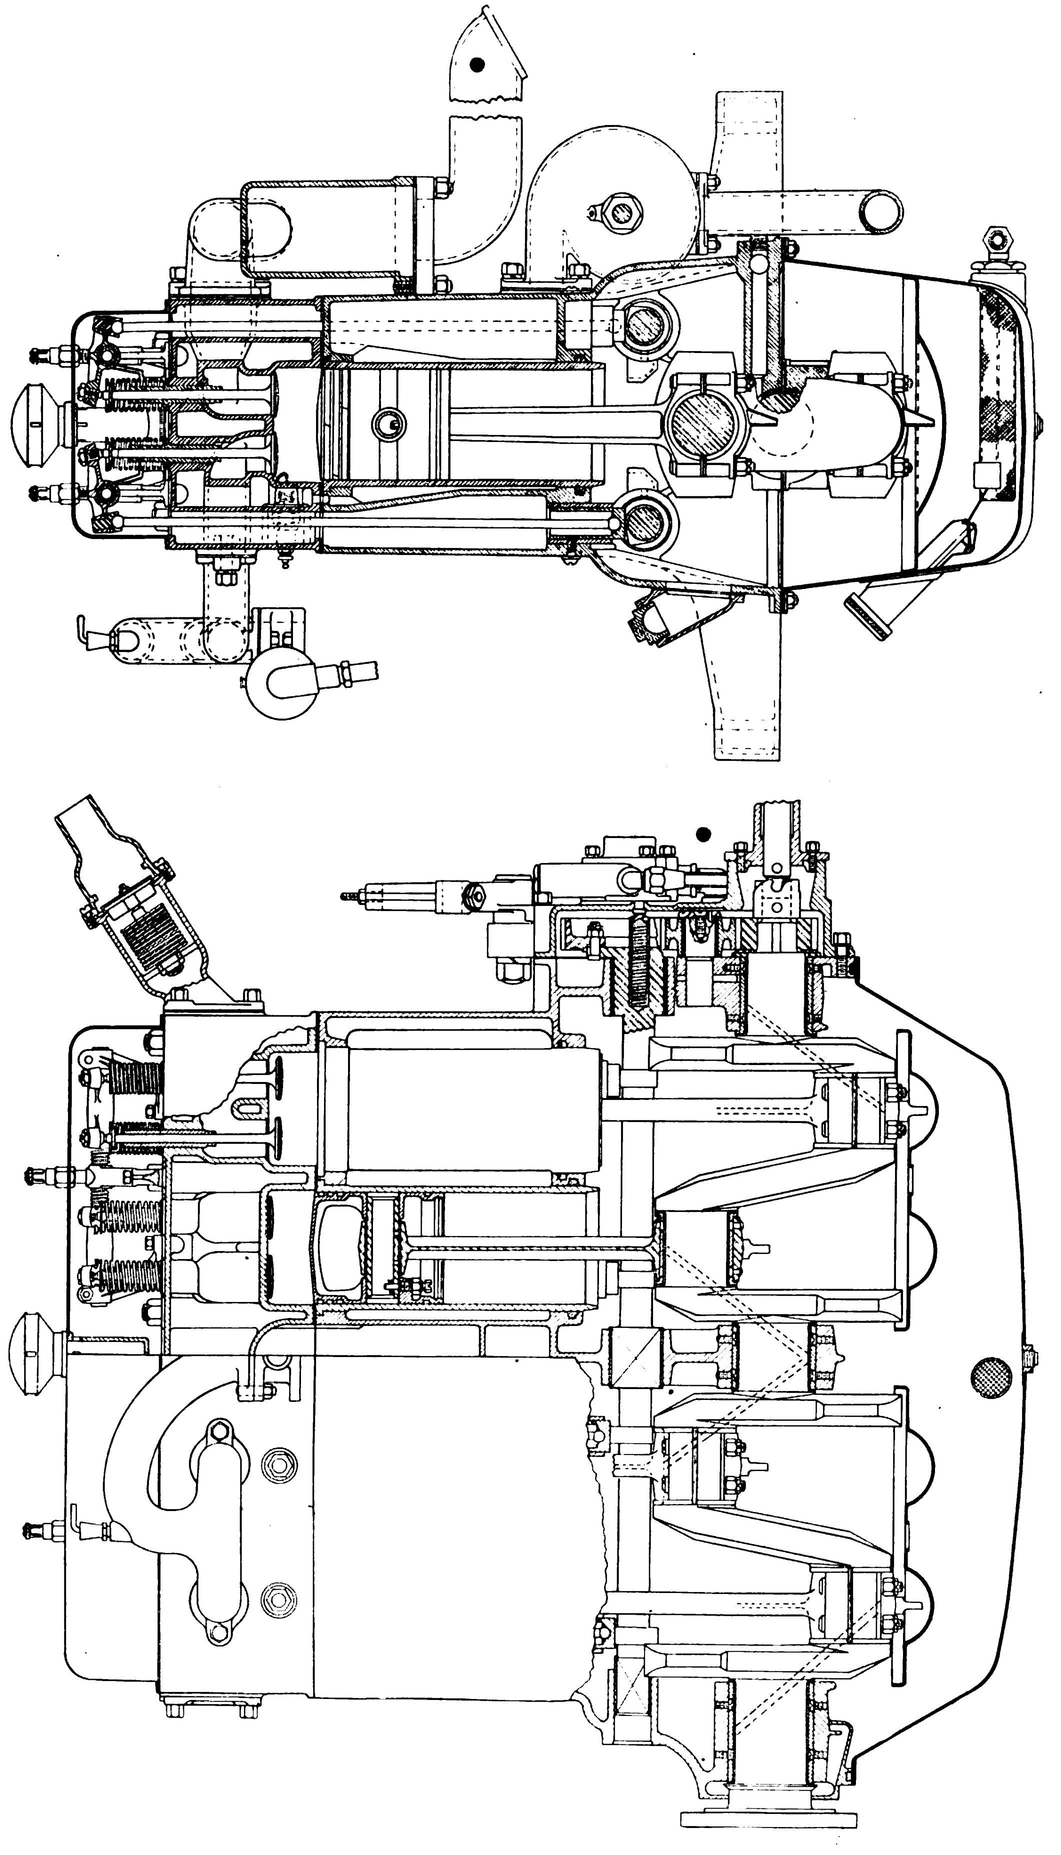
The engine power is delivered to the transmission through a Borg & Beck clutch operated by a foot lever. Access to the clutch for inspection or adjustment is provided for by a large hand hole in the bell housing.

The fuel tanks are mounted on a cast-iron saddle, which in turn forms a large cover plate over the clutch and gear-shifting mechanism.



Operator's seat and controls of the Twin City tractor

Twin City Four-Cylinder Sixteen-Valve Tractor Engine



Side and end sectional drawings of the Twin City tractor engine, which is the first tractor engine to be equipped with double intake and exhaust valves. Valves are in the cylinder head at the corners of a square, those on one side being the intakes and those at the other the exhausts

The power is delivered from the clutch shaft to the first countershaft through a pair of bevel gears. Two sliding change-speed pinions are mounted on this splined countershaft, which in turn engage either the high or low-speed intermediate gears mounted on the intermediate shaft, with the main drive pinion between them.

The main pinion engages the differential ring gear secured to the differential spider, in which four pinions are mounted. These in turn engage with the two differential bevel gears into which the splined inner ends of the rear axles are fitted. The two forward speeds are 2.2 and 2.9 m.p.h., and the reverse is 1.75 m.p.h. Gear reductions are 51:1 for the high and 68:1 for the low gear.

The differential is assembled as a complete unit, and is mounted independently on large Hyatt roller bearings located at the inner ends of the axle housings.

The transmission case and front frame castings are of semi-steel. All transmission gears, except the two large intermediate gears and the differential ring gear, are steel drop forgings, accurately machined and case-hardened to insure maximum service. The two large intermediate gears and the differential ring gear are rolled steel forgings of 0.45 carbon steel, accurately machined and heat treated. All gears are of generous proportions and are of the 20-deg. stub-tooth type.

The transmission shafts are made of 0.40 carbon steel, heat treated, and ground to exact limits, and possess great strength. They are mounted on Hyatt roller bearings throughout, and wherever thrust loads are encountered, due to bevel gears, ball thrust bearings are employed. The clutch shaft is piloted on a single annular ball bearing mounted in the flywheel. The total gear reduction for either forward speed is accomplished in three steps. The entire transmission runs continually in a bath of oil. Transmission lubrication, therefore, requires absolutely no attention on the part of the operator.

The drive wheels are 50 in. diameter and 12 in. face, with flanged rolled-steel rims and forged-steel "Tee" head spokes. The hubs are splined, and are a push fit on the rear axles. Each is secured in place by a large castle nut which clamps the wheel against a shoulder on the axle.

The drawbar, which is a steel drop forging, spring mounted, provides a liberal lateral adjustment and is attached to the rear part of the transmission case. A

Believes in Four-Cylinder Engines

Declares Smooth Operation Is Possible with Four-Cylinder Design as Well as with Greater Number of Cylinders

By Lawrence H. Pomeroy *

MY first impression of American design is the lack of attention which has been paid to the possibilities of the four-cylinder engine in its application to the first-grade automobile. One feels that, as a result of the earlier development of the four-cylinder engine in America, which tended toward large engines running at comparatively low speed, the line of recent development has been toward the multi-cylinder engine, in conjunction with a very low top-speed gear ratio. So that from the point of view of the motor, the impulses per revolution are increased in proportion to the number of cylinders, and from the point of view of the car as a whole, the revolutions of the engine are increased in accordance with the gear ratio.

The general effect is, therefore, that the tendency of design has swung heavily in the direction of obtaining even engine torque at low car speeds. It seems questionable as to whether the effect mentioned is worth the considerations involved in producing it.

Smoothness of Four-Cylinder Engine

The capacity of the senses to appreciate variations in engine torque, or, to speak more correctly, variations in engine torque reaction, is limited. For example, in using alternating current for electric lamps the eye cannot detect any variation in the intensity of the light if the periodicity of the alternating current is more than 40 cycles per second. The eye is probably the most sensitive of the human organs, and it would be a matter of considerable interest to determine the corresponding periodicity which could be detected, arising from torque variation in an automobile. In fact, the experience gained in Europe during the past 4 years is that, with the four-cylinder engine, the smoothness of running, even at quite low car speeds, is such that it is very difficult, indeed, to distinguish between a four-cylinder engine and one with six or more cylinders.

The simplicity of the four-cylinder engine from other points of view is apparent. Its chief defect—that is, the fact that severe secondary unbalanced forces are set up which produce annoying periods and vibrations—has been completely overcome by recent inventions which are worthy of a more complete description than can be given from a series of somewhat casual impressions as are here set down.

There seems to be a feeling that in order to obtain hill-climbing capacity on top gear and good acceleration, a multi-cylinder engine is essential. The determinant of the above qualities in any car depends upon the ratio of total horsepower to total weight at any given car speed. There is not the slightest difficulty in making this ratio whatever may be desired, irrespective of the number of cylinders.

For example, a well-known American car develops some 40 hp. at 1000 r.p.m., at which engine speed the car speed is about 22 m.p.h. The weight of this car is about 4400 lb. At 22 m.p.h., therefore, we have approximately 1 hp. for every 110 lb. In a four-cylinder engine which was developed in Europe before the war the horsepower developed at a car speed of 22 m.p.h. was 27 hp. for the car weight of 2500 lb.—that is, 1 hp. for every 92 lb. of weight. The capacity for acceleration and hill climbing on top speed is therefore some 12 per cent better than in the American multi-cylinder car, and there is practically no perceptible variation in torque at low speeds.

As a matter of interest, the acceleration which could be obtained on low speeds was such that if the car was suddenly accelerated upon reverse, the passenger climbing into the front seat would find himself falling out over the fenders. Even with the same ratio of horsepower to car weight, the acceleration obtainable with a four-cylinder engine is better than with the multi-cylinder, due entirely to simpler induction pipe design.

American Car Not Economical of Fuel

From the point of view of fuel economy, the American car does not strike one as approximating any degree of efficiency. A consumption of 32 to 36 ton-miles to the gallon can easily be obtained with a modern four-cylinder engine, whereas with a multi-cylinder car the consumptions seem to be more on the order of 11 miles to the gallon, or 22 ton-miles for a car of 2 tons weight.

From the point of view of oil economy, the consumption of 1 gal. for 1000 to 1200 miles is quite usual on the modern European engine.

The multi-cylinder, in general, contributes very

**Editor's Note.—L. H. Pomeroy recently arrived in the U. S. A., where he hopes to remain and establish manufacturing connections. In England he was chief engineer and executive manager of the Vauxhall company, maker of the Vauxhall car, which established such a favorable reputation for itself in the last few years. The new 30-98 four-cylinder Vauxhall is reported to be one of the best performing cars in England.*

largely to the difficulty of carburetion. It is possible, in my view, to obtain very much better warming up with the four-cylinder engine, due to the fact that the induction passages are of greater area, than with the multi-cylinder engine. Further, the smallness of the individual cylinder on the multi-cylinder engine and the large area it offers to the cooling water adversely affect the point in question. The general proposition as to the number of cylinders necessary for an automobile is determined principally by the total load to be carried and the nature of the body work. For very heavy and luxurious cars there is certainly a case for the multi-cylinder engine, but the arguments therefore do not carry anything like so much weight, in my opinion, when the object of the car is to transport four or five people with adequate comfort in an open body. This leads to the probability that in future the chassis for an open touring body will be developed upon quite different lines from that for closed body work.

With respect to chassis design in general, the manufacturer of complex parts seems to have obtained such a high level in America that designers feel themselves independent of any present need for reduction in cost of manufacture by design alone.

Concluding this very brief impression, I feel called upon to express my great admiration of the methods of manufacture and the very high class of workmanship which so far I have seen. This problem has been tackled in a very whole-hearted and thorough way, and there is no doubt that the American high-grade car is deserving of the very greatest respect from European engineers.

Hilliard Clutch for Trucks and Tractors

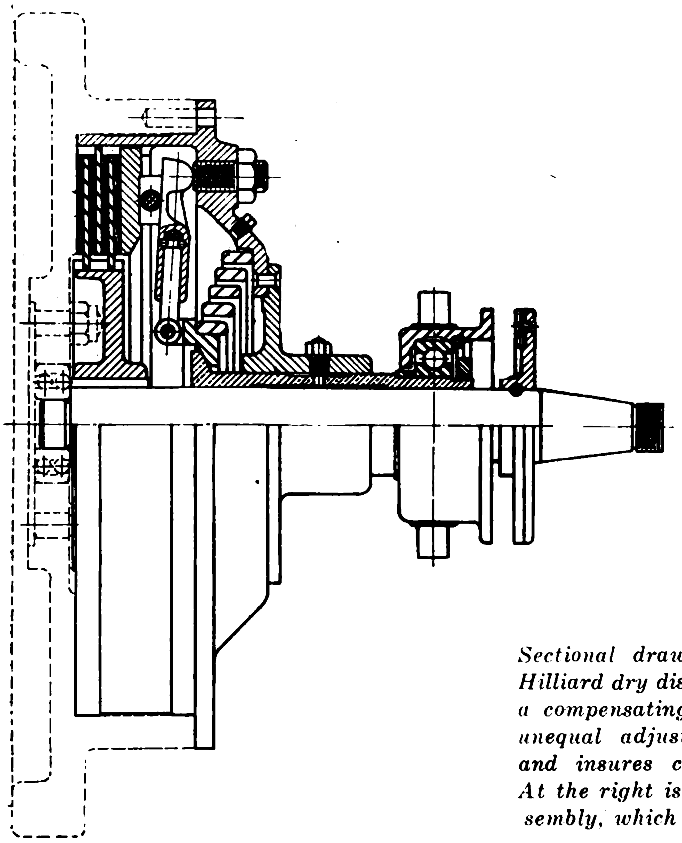
A NEW design of heavy duty clutch for use on trucks and tractors has recently been placed on the market by the Hilliard Clutch & Machinery Co., Elmira, N. Y. This firm has been manufacturing friction clutches for trucks, tractors and stationary power transmission purposes for the past 12 years. Its truck clutches in the past have been of the larger size only, having a rating of 75 hp. and over at 1000 r.p.m. To meet the demand for heavy duty type clutches for use in connection with engines of smaller ratings, the firm has now developed its types X and XU clutches.

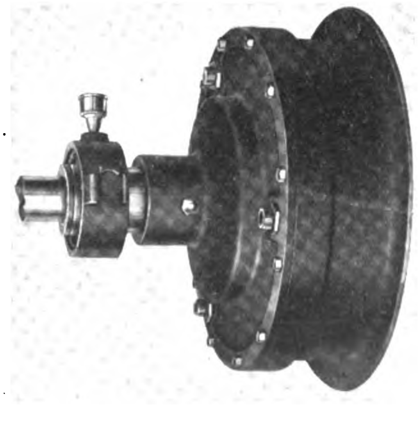
These clutches are of the dry disk type, and comprise two driven disks and one central driving disk, not counting the presser plate and the flywheel web, which also serve as friction surfaces. The friction disks are compressed by means of three levers, which are connected to a compensator ring, surrounding a sleeve on the clutch shaft. These levers bear against rollers, supported by lugs on the presser ring, and their outer end takes purchase against a set screw in the housing. These set screws serve the purpose of adjustment.

The special feature of the clutch is the compensating ring to which the lever arms are attached. This has a tapered surface which coacts with a spherical surface on a flange on the sleeve on which the shifting collar is mounted. Owing to the use of this compensating ring, if the different set screws should be unequally adjusted, or if there should be unequal wear on the disks, this will not affect the perfect operation of the clutch, as the compensator ring will so adjust itself that the pressure will be uniform over the whole surface of the disks. The clutch shaft is provided with a pilot extension, which by means of ball bearings, can be mounted inside of the flywheel. The shifter collar is provided with radially extending pins, adapted to engage with a forked lever. The rear end of the shifter collar is flanged outward, and is adapted to make contact with a disk on the clutch shaft, provided with a friction facing, which serves as a clutch brake. While the compensator ring tends to automatically equalize the pressure on the friction disks, it is nevertheless recommended to always keep the adjusting screws equally adjusted.

The matter of lubrication of the clutch has been fully attended to. A grease cup is provided for the trunnion bearings, and there is a small oil cup on the shifter sleeve. In order to insure proper lubrication of the pilot ball bearings, a small amount of oil is injected through a plugged filler opening in the housing of the clutch.

These clutches can also be operated with an oil bath, in which case from one pint to one quart of medium machine oil is poured into the housing.





Sectional drawing of the new Hilliard dry disk clutch in which a compensating ring allows for unequal adjustment and wear and insures correct operation. At the right is the complete assembly, which is fully enclosed

The Engine of the Side Car Motorcycle

An Analysis of Features of Cycle Engine Construction in a Paper Presented to the Institution of Automobile Engineers by E. Caudwell

FOLLOWING up its decision to give some attention to motorcycle engineering matters in the future, the Institution of Automobile Engineers recently has had two papers on motorcycle topics presented to it. The first of these, by D. S. Heather, contained a general critique of current motorcycle design, based on personal experience as a rider. The second, just to hand, deals with motorcycle engines from the standpoint of the designer and engineer.

The first part of Mr. Caudwell's paper is of a somewhat general character and may be briefly summarized. He points out that there are on the market to-day five varieties of engine:

(1) The single-cylinder.

(2) The Vee twin-cylinder with an angle of 55 degrees or less between the axes of the cylinders.

(3) The Vee twin-cylinder with an angle of 90 degrees between the axes of the cylinders.

(4) The horizontally opposed twin-cylinder, and

(5) Four cylinders in line.

The discussion is limited to air-cooled engines of over 31 cu. in. piston displacement. The author states that air cooling would be very difficult under right conditions but that very little attention seems to have been given to its improvement. To bear out this statement it is pointed out that a careful examination of a 1906 Minerva 3½-hp. engine cylinder and any 1919 cylinder shows no essential differences in design except that the valves and passages are somewhat larger. Better cooling, the author says, is undoubtedly badly needed, as it will give longer life of valves, less carbonization, and, in permitting the use of a higher compression ratio, will improve thermal efficiencies—and therefore fuel consumption.

As an indication of the large scope for improvement, Fig. 1 shows the tractive effort of a 4-hp. motorcycle engine. It will be noted that while it amounts to 90 lb. at 18 miles per hour, it falls away steadily until at the very moderate speed of 36 miles per hour it has dropped to 64 lb., showing that as the engine revolutions increase the mean effective pressure steadily decreases. This indicates not only inefficient cooling, but restrictions in the valve ports and passages. As a fully laden side-car outfit may weigh 700 lb., the commencing values are quite creditable, but the engine should hold its torque over a considerable range before the curve turns downward.

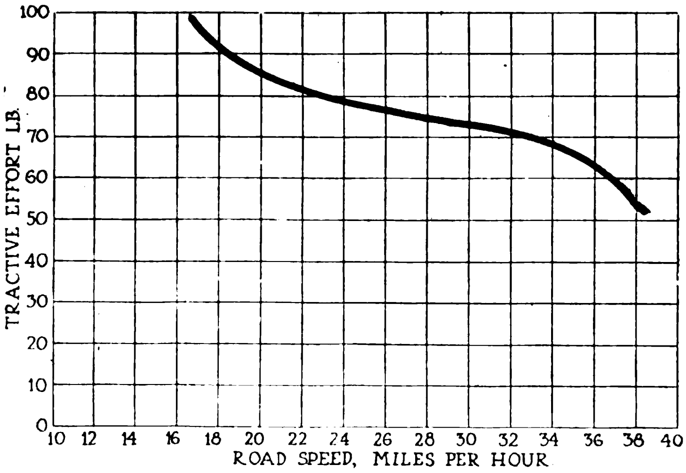


Fig. 1—Tractive effort of motorcycle engine

Next the subject of engine balance is taken up and inertia force and crank effort diagrams are given for each type. The results arrived at, with the aid of a theoretical indicator diagram, may be given most conveniently in the form of a table. All crank efforts are figured for 1700 r.p.m., and the assumed pressure diagram is such as to give 90 lb. per sq. in. mean effective pressure, and therefore about 80 lb. brake mean effective pressure.

Engine Type	Bore and Stroke, mm.	Crank Effort in Lb. In. Max. Pos.	Max. Neg.	Mean, for Entire Cycle	Ratio of Crank Effort Range to Mean
Single Cylinder Vertical	85x99	1950	300	242	9.3
55 Deg. Vee Twin	85x88	1920	410	432	5.16
90 Deg. Vee Twin	85x88	1970	360	432	5.4
Flat Twin	74.5x68	990	300	257	5.02
Four Cylinder Vertical	52x88	500	0	345	1.45

The values given for the variation in crank effort for these five types of engines are of course a measure of the flywheel capacity required, the single-cylinder needing the heaviest flywheels; the 90 degree Vee and the 55 degree Vee and the flat twin engines have lighter flywheels in the order given, and the 4-cylinder engine the smallest of any.

These figures have an interesting bearing on the transmission question, as the more jerkily the power is applied, the more wear and tear it causes, so that everything has to be made correspondingly heavier and stouter to withstand it, and although makers of single and twin-cylinder engines nearly all provide shock absorbers, these can hardly be regarded as a mechanical expedient. It is difficult to make a satisfactory one, although there are several types available. Some prefer a form of clutch which can be so adjusted that it only slips when the power impulse reaches its maximum value, but experience shows that this type is very difficult to regulate, as it usually either slips all the time or is locked solid.

Better results are obtained with a type which drives through a spring, but here again the springs have to be adjusted very carefully, and when they weaken through use they will simply shut up solid and give a rigid drive. In any case they are a source of waste of power, as if energy is used in slipping a clutch or shutting a spring, it is not available at the back wheel for propelling the vehicle. Such devices, therefore, can only be regarded as attempts to render an uneven drive tolerable.

Crankshaft and Flywheels

It is difficult to understand why makers of single-cylinder and Vee twin-cylinder engines, with few exceptions, have always placed the flywheels inside the crankcase; the disadvantages of this method of construction are numerous and obvious, while advantages seem to be non-existent. As the engine width has to be kept narrow, two flywheels can only be employed at the expense of bearing space. A car engine with an 85 mm. bore cylinder has a crankpin about 2 in. diameter by 2½ in. long, so that it is extraordinary that there should be many thousands of motocycle engines running with crank-

pins only ¾ in. diameter by 1¼ in. long, and still more extraordinary that, although the oil is only fed in a most erratic manner with a hand pump, they may yet last 5000 miles without requiring renewal—that is, about six months' work for a fairly hard rider. Although some improvement has been effected by the use of roller bearings, these can hardly be regarded as a satisfactory solution of the problem in view of their small size and the heavy loads and shocks to which they are subjected.

The placing of the flywheels inside the crankcase means, too, that the diameter cannot exceed about 8 in., so that they have to be unduly heavy. The average weight is from 25 to 35 lb. the pair, which is about one-third the total weight of the engine. It is also an expensive method of construction, as the crankpin and the two sides of the crankshaft are all separate pieces, which have to be fitted into the flywheels with tapers and keys, and pulled up with nuts which require to be securely locked.

In order to renew the connecting-rod big end bush, the flywheels have to be separated, and every practical rider who does his own repairs knows the difficulty of getting them to run true again, if they ever do at all.

Bearing Sizes Inadequate

Bearing sizes, too, seem quite inadequate, although these are usually of the ball or roller type. We find that one well known maker of ball bearings lists a ⅞ in. by 2 in. by ⅝ in. bearing specially for motorcycle crankshafts, and this size has been used on innumerable engines. Although it is a wonderful testimonial for the makers that these bearings may have a life of over 10,000 miles, it is short as compared with that to be obtained from the size of ball bearing that car manufacturers would employ for the same duty. If, on the other hand, a solid crankshaft is used in conjunction with an outside flywheel, the bearing surfaces can be brought up to more adequate dimensions, and the flywheel weight reduced by increasing its diameter. In this respect the flat twin engines at present on the market present a very much more satisfactory design.

However, the first four types of engines we are dealing with are all cramped for bearing space, as their width must be kept down to that which will go comfortably between a rider's feet, while the four-cylinder engine, with its axis coincident with the longitudinal axis of the machine, is practically unrestricted.

Fig. 2 shows a section of the crank, piston, and connecting-rod of a 90 mm. by 130 mm. touring car engine, and of an 85 mm. by 88 mm. motorcycle engine. Both are drawn to the same scale; as the differences are so obvious, comment is unnecessary.

Piston and Connecting-Rod

The question of the design of the connecting-rod is rather tied up with that of the crankshaft, as, with internal flywheels, the usual type having a plain gunmetal bush or roller bearing big end is obviously the best, but if a solid crank is employed, it permits of adequate bearing surfaces and a car type of rod with a split big end and white metal bearings, although even in this case ball or roller bearings may be used, as they can be arranged to thread on over the crank webs.

The restrictions connected with the use of internal flywheels limit the distance between them to about ⅝ in., so that the connecting-rod is not wide enough to resist transverse strains. This results in the rod springing, so that it is usual to find that the piston pin is not parallel with the crankpin after a very little use.

All piston pins at present in use are hopelessly inadequate in size; in many engines they are only ½ in. in diameter, and, while a few are larger, there are none to be found exceeding ⅝ in. As a piston pin ⅞ in. in diameter can be easily fitted into an 85 mm. piston, it is difficult to account for this preference for the small sizes used, especially as their life is extremely short. In spite of the many different ways in which piston pins are held in the piston, there is still a great deal of trouble caused through their working loose, although this is probably due to the fact that the small dimensions of the pin in the first place do not allow sufficient bearing in the piston bosses. Of all the different ways of

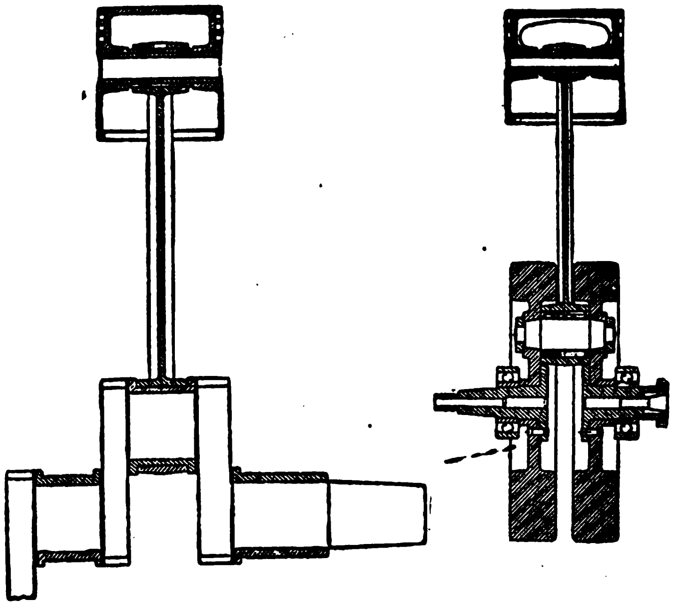

Fig. 2—Section of crank, piston and connecting rod, 90 by 130 mm. touring car engine and 85 by 88 mm. motorcycle engine

fixing piston pins, it would be hard to find a better than that employed for many years by a leading manufacturer, which is to make both ends of the pin of an exceedingly fine taper—one in 1600—and to drive it into a carefully reamed hole in the piston. When properly made, this gives an absolutely perfect fixing which never permits the pin to work loose. Although it appears an expensive method in the first place, it can easily be done on a commercial basis, to judge by the quantities which have been turned out.

Little can be said with regard to pistons, as we do not yet seem to have attained to any definite ideas as to what does actually form correct design. It is to be hoped that before long the aluminum piston will be thoroughly tried out to prove whether it is suitable for everyday use in an air-cooled engine, as if so, it presents distinct advantages in the way of lightness, better cooling and freedom from carbonization.

The subject of carburetion does not appear to have received the attention it deserves, as in spite of the long continued demand which has been put forward through the technical press for a truly automatic carbureter, the author does not know of a single British manufacturer who fits one as a standard. A certain number have been made, and one or two makes have attained a considerable measure of popularity, but the rider who wishes for one has to fit it at an extra expense after purchasing a machine; yet there is no doubt that if the motorcycle is to be placed on a level with the car, an automatic carbureter is a necessity. The present two lever type is an exceedingly primitive device, although in skilled hands it can be made to yield surprisingly good results. What we require, however, is an instrument which will give the best results independent of the skill of the driver, once it has been correctly set.

As the success of an automatic carbureter very largely depends on even suction, it is an exceedingly difficult thing to design a satisfactory one for a single-cylinder engine where the suction is only exerted for half a revolution out of every two, and then stops and starts again with a violent jerk. The conditions are nearly as bad with the irregular suction intervals of the Vee twin-cylinder engines, and it is only with the flat twin and the four-cylinder engines that conditions are obtained which render an automatic carbureter a success. These two types of engine can be fitted with any of the car type carbureters which are on the market, such, for instance, as the Claudel, or the Zenith, to name two well known examples, in which there are no moving parts except the throttle.

The flat twin engine appears to be subject to a good deal of trouble on account of the length of the induction pipe, as the two inlet valves are at opposite ends of the engine, but the

difficulties here should be easily overcome by exhaust jacketing the pipe and providing a hot air supply to the carbureter from a muff on the exhaust pipe. It is certain, too, that the heating of the air supply requires careful attention on a four-cylinder engine, as it has to be remembered that in the present state of development the motorcycle engine is running absolutely exposed to the elements, unlike a car engine which is closed up inside a bonnet, and always surrounded by fairly warm air.

The American manufacturers have progressed much farther than we have in this matter of carburetion, as their machines are universally fitted with an automatic carbureter, although they do not appear to be of the best type, insomuch that they are provided with too many adjustments which are under the rider's control.

Lubrication

As with carburetion, the lubrication of most English engines seems in an embryonic state, and in this respect, too, the Americans have a decided advantage, as mechanical oiling is universal on their machines. Very few English makers of a single-cylinder or Vee twin-cylinder engine appear to have got beyond a hand-pump or sight feed drip. The former over-oils the engine at irregular intervals, depending on the whim of the driver, while the latter is decidedly erratic, and requires frequent readjustment to suit the varying viscosity of the oil under different atmospheric temperatures.

It is satisfactory to note that the makers of the flat twin and four-cylinder engines have brought their lubrication systems into line with modern practice, which is a pump driven by the engine drawing oil from the bottom of the crankcase and delivering it into troughs into which the connecting-rods dip, the surplus oil running down through a filter to be used again.

For the sizes of engine we are dealing with, there is no need to consider forced lubrication with its extra complications in the way of pressure filters, relief valves, etc., which require periodic attention. When the trough system is employed there is no need to use any filter except a gauze tray below the troughs and covering the whole of the base. Its area is then so large that cleaning is never required between overhauls of the engine.

We can say that a correct method of oiling has been evolved, and it only remains for all makers to adopt it.

A brief acquaintance with motorcycle engines is sufficient to convince anyone that most valve gears are very noisy after quite a short period of running. Complaints are also general of undue noise from the exhaust, but we are never likely to have really effective silencers until the mechanical noises from the engine have been reduced, as, for a choice of evils, the bark of the exhaust is preferable to the scream of the timing wheels, though frequently in some engines at high speeds the mechanical noises drown the exhaust. The causes of noisy valve gear are chiefly the inadequate bearing surfaces through lack of space, and incorrect cam forms, particularly those of the internal variety.

With the conventional construction of crankcase with internal flywheels, the cams, wheels, bearings, and rockers have all to be packed into a space about 1¼ in. wide. This compartment is separated from the crankcase by a wall, and usually only gets lubricated in a haphazard manner by the oil mist which passes through the crankshaft ball bearing. Examination of a considerable number of timing wheels shows the bearing on either side of the wheel to have an average diameter and length of 10 mm., and it runs in a hardened steel bush pressed into the crankcase, rarely pinned in any way to prevent it rotating. The timing case cover carries the bushes on one side, and is seldom dowelled, and is only held on to the crankcase by means of screws with clearance holes.

The chances are that the bearings are never put up correctly in relation to one another, and as it is very difficult to get an adequate supply of oil into them, they all very soon wear slack, while the bushes get loose in the aluminum. Also with the loose fitting timing cover, the centers of the respective holes are out of parallel with each other, so that the whole mechanism is generally running out of truth on badly worn bearings, to the consequent accompaniment of the noise previously referred to. Although this type of timing gear does not lend itself to the best design, a considerable improvement could undoubtedly be made by mounting the wheels on ball or plain bearings of more adequate diameter, and dowelling or piloting the cover on the crankcase, or, as on one make of engine, carrying the bearings in a frame which is independent of the cover. Some better means, too, should be taken to insure lubrication of the timing gear, which can easily be done now that mechanical oil pumps have become a necessity for the engine of the future.

(To be continued)

Steaming of Vehicle Stock During Kiln Drying

SATURATED steam as a means of alleviating the tendencies of green lumber to honey-comb in the kiln has for some time been successfully applied in the commercial drying of heavy vehicle stock. Under intelligent control, such treatment has meant the difference between success and failure in many kiln runs.

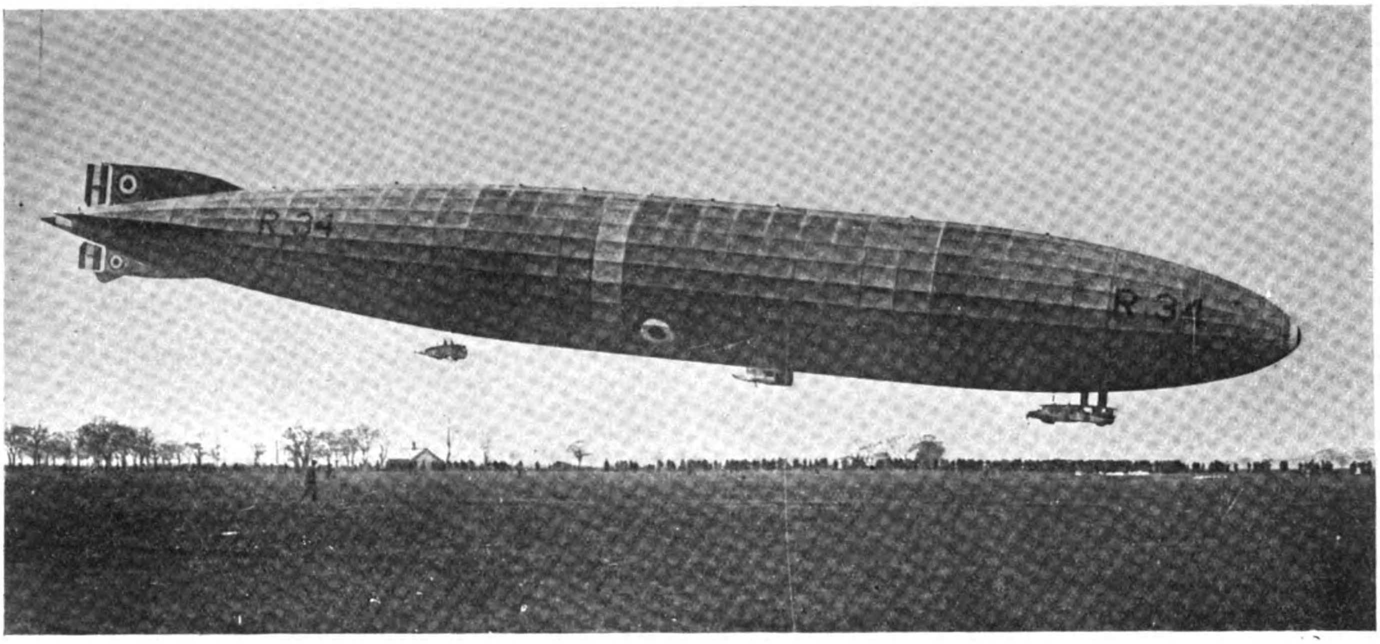
So far, however, the steaming treatment has been confined to straight stock. The contention has always been that bent stock, such as rims, should not be steamed after removal from the form, experience indicating that stock so treated would tend to straighten out to its original shape.

Recent experiments conducted under the direction of the Forest Products Laboratory have shown that judicious steaming of heavy bent vehicle stock results in a considerably improved product, and that the operation can be accomplished without serious effect upon the curvature. Careful judgment is necessary, however, as it is a very easy matter to ruin the entire charge by too severe treatment. Contrary to the common impression, this steaming has been done at high temperatures (150 to 180 deg. F.) and for short periods (½ to 3 hours), the temperature and time varying according to the requirements of the case.

The method was given a rather severe test, being tried first on 56-in. oak rims and later on 60-in. artillery wheel stock. When applied to the kiln drying of heavy oak rims on a commercial basis it worked out very successfully. Checks in the stock before steaming, which showed "pinching in" tending toward honey-combing, closed normally without further damage after steaming. From kiln charges totaling about 2400 pieces, the losses attributable to kiln drying were only 2 per cent.

Co-operative Manufacturing Suggested

IN discussing a paper on Jigs, Tools and Special Machines before the Institution of Mechanical Engineers in London recently, Herbert Carpenter said he would suggest that the Government should call the motor car manufacturers together and get them to form a committee to consider standization. There were 200 or 300 cars on the British market, with not so much as a piston ring standardized. Such a committee might develop designs embodying the best features of every car, and a dozen types might be standardized, embracing light cars, taxicabs, trucks and delivery wagons, together with two or three other essential types. They could evolve five or six types of engine and one or two magnetos, while they could standardize carbureters, valves and piston rings. The making of small fittings could be specialized by the smaller firms, engines by larger firms, and motor cars by firms still larger. Wit hsuch a system, connecting rods should be produced at a cost of 20 cents per rod, and generally the price of cars be reduced to pre-war limits. It might be urged that the scheme would arrest improvement and invention, but he thought that a manufacturers' committee would be well able to judge of the desirability or otherwise of a proposed improvement.



The R-34, 670 ft. long, descending after her trial trip at Clydeside. Over 400 men and women assisted in launching this ship, which remained in the air 4½ hours

The Inauguration of Safe Aerial Transportation

Helium Gas for Balloon Inflation and the Likely Results of Discovery of Means for Producing It Cheaply in Quantity

By Harold F. Blanchard

THE complete safety of aerial travel is assured by the recent discovery of helium gas, or rather a method of producing it. With its use a dirigible airship may float as securely in the air as a ship at sea, and, in fact, more securely, as will presently be explained. Airships have always been considered safe, except for the bugbear of fire due to the use of hydrogen, that most inflammable of gases, to inflate the bag. But now helium, the only other gas that is sufficiently light, has been made available, and helium is just as fireproof as hydrogen is the contrary.

Already plans are being laid for the construction of mammoth passenger-carrying dirigibles resembling the Zeppelins, and these ships, luxuriously fitted, will presently ply by straight line routes between the big cities. They will be easily capable of making non-stop voyages half way around the globe, and even a complete circuit of the globe without a landing is not an impossibility. This is not a hackneyed prophecy uttered in a burst of enthusiasm, but the conservative conclusion that must be reached after due consideration of the facts, particularly the announcement of a process for producing helium recently made by the Navy Department.

The size and lifting capacity of the big dirigibles with rigid gas bags, and therefore called Zeppelins, are staggering, but are really only an earnest of what is to come. A modern Zeppelin has a gas bag approximately 650 feet long and 75 feet in diameter, and contains 2,000,000 cubic feet of gas; it has a total lifting power of 130,000 pounds, or 65 tons, 1400 horsepower and a speed of 75 miles per hour. Such a ship has a load capacity of 38 tons, or 58 per cent of the total lifting capacity, and has a non-stop cruising radius of several days, the distance depending on the speed and how much of the load-carrying capacity is used for fuel.

Such are the characteristics of the German Zeppelin. The British, with an eye to air supremacy, as necessary from their standpoint as their preponderance of sea power, have also developed this type. The *Daily Mail*, London, recently published the first particulars of one of the latest types of British rigid airships, the building of which has been done secretly. These vessels are known as the "33" class and are equal in size to the most successful type of Zeppelin, and preliminary tests have shown that they will equal, if not exceed, the Zeppelin performances.

The first of this type has been built for the admiralty and was originally designed for ocean-going war service. The craft has a length of 670 feet, a diameter of 79 feet and a capacity of 2,000,000 cubic feet. She will carry fuel for a continuous flight of eight days and a speed of at least 70 miles per hour is promised. Such a ship could easily travel half way around the globe, and yet, large as it is, it is small compared to what Great Britain is planning. There is under consideration by the admiralty a ship practically five times as large as this.

Complete details are lacking, but it is to be 1000 feet long, have a gas bag capacity of 10,000,000 cubic feet, and a lifting capacity of about five times, or roughly 200 tons. It will be driven at a maximum speed of 80 miles per hour by engines of 8000 horsepower. There is no limit to the cruising radius of such a machine.

It is difficult to visualize 38 tons, let alone 200, because the average man's experience with tonnage is limited to coal. Perhaps the most striking illustration is to compare the lifting power of these ships with that monster flying boat belonging to our Navy, which recently carried fifty-one men. This machine, perhaps the largest of its kind in the world, has a lifting capacity of only 6½ tons.

These big liners, equipped with all the luxuries known to land and sea travel, will carry passengers and freight to the corners of the earth and will also be used for safe aerial transportation between distant cities in our own land. Even a present-day Zeppelin would carry as many passengers as the justly famous Twentieth Century Limited, which runs between Chicago and New York, making the trip in 20 hours, which figure the big airship would more than cut in two.

On a basis of an 80-mile-an-hour speed, the time it would take to run from New York to various distant points is given below:

	Days
Melbourne	5½
Hongkong	5¼
Calcutta	4¾
Tokyo	3¾
Cape Town	3¼
Buenos Aires	2½
Petrograd	2½
London	1¾
Paris	1¾
Sitka	1½
Los Angeles	1¼

Up to the announcement of the discovery of helium conservatively minded people rightly questioned the safety of aerial transportation. The aeroplane is rather dangerous and likely to remain so, and the airship filled with inflammable hydrogen was likewise out of the question. The sudden destruction of several Zeppelins in flames and the memory of our own ill-fated Vaniman, who lost his life when the machine with which he was attempting to cross the ocean took fire in sight of the Atlantic coast, give sufficient proof, if any were needed, of the hazard of hydrogen.

Helium Is Non-Inflammable

But the production of helium gas in quantity has completely eliminated the fire risk. Helium is a non-inflammable gas somewhat resembling nitrogen, except that it is much lighter. Its existence has been known for a good many years, but until recently so difficult was its extraction that not more than a half dozen cubic feet were ever segregated in one container.

Compared with hydrogen it has a lifting efficiency of 93 per cent. Next to hydrogen it is the lightest gas known. Although its weight is twice that of hydrogen its buoyancy is 93 per cent because of the relatively high weight of air, which is approximately 14.4 times that of hydrogen. Eight per cent greater volume of helium is required to give a lifting power equal to hydrogen, but this difference is not sufficient to cause any difficulty.

The production of helium in quantity is a result of the war. When the United States entered the conflict, Great Britain turned to us for co-operation in solving many problems which would aid in terminating hostilities. Among many others the problem of producing helium in sufficient quantity to enable its use in dirigibles in place of hydrogen was presented.

Uncle Sam, as typified by the Bureau of Mines, scratched his head and looked around, first to see where in this vast country helium was hidden in sufficient quantity to warrant consideration. His card index of the country's resources told him that helium occurred in various places, in the air, in certain minerals and mineral waters, but in exceedingly small quantities. But the natural gas coming from Oklahoma, Kansas, Texas and Ontario contained 1 per cent of the coveted helium, and this source held out great promise.

Pure helium was obtained from natural gas by a very simple process. Natural gas is a mixture of several gases and helium has the lowest boiling point of any of the constituents, so that by cooling the gases down to a temperature of 317 deg. below zero Fahrenheit, all were liquefied except helium. A method for producing helium on a grand scale along these lines was developed by the Linde Air Products Co., and the Navy Department forthwith gave them a contract for erecting buildings and equipment to the value of $900,000 at Forth Worth, Tex., with the understanding that they should be ready for production in April, 1919. The plans also include a 10-in. pipe line from Petrolia, Tex., costing $1,000,000. Although the plant is not yet in operation, it is estimated with accuracy that the cost of helium will be as low as $100 per 1000 cubic feet, and with increasing use it will undoubtedly go much lower.

There is no brighter page in the romance of chemistry than that devoted to this gas, and inasmuch as the history of its discovery and development is very closely linked with its present production in quantity it is worth while to stop a moment and briefly review it.

Helium Found in Sun Spectrum

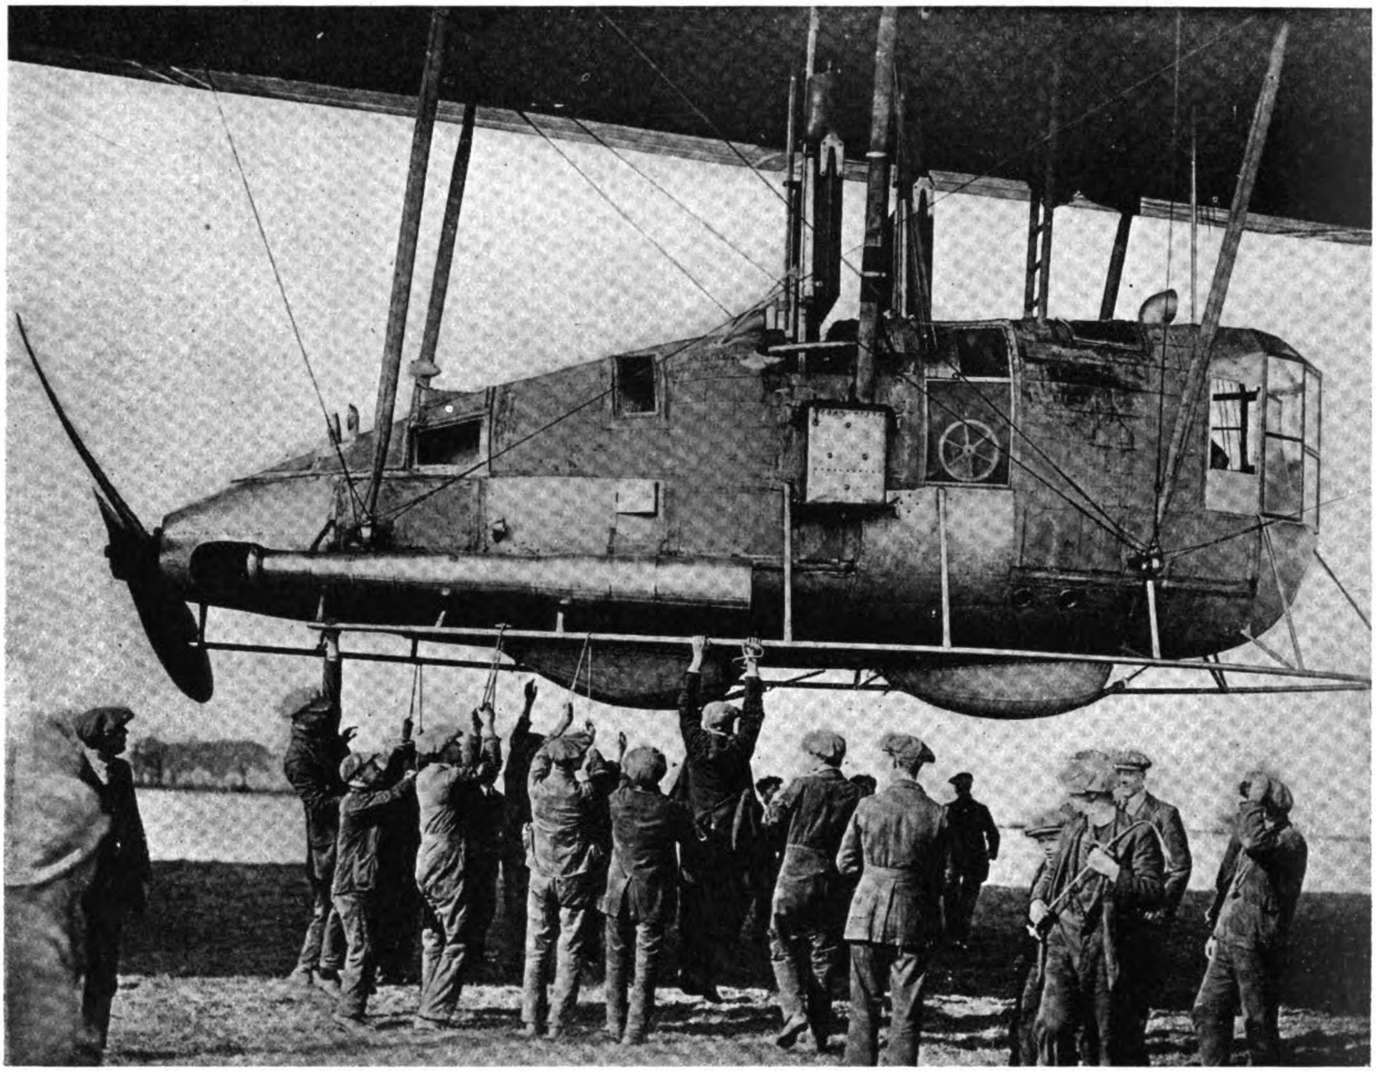
It takes its name from the Greek word helios, meaning sun, because its presence was first noted in the incandescent atmosphere surrounding the sun. Every incandescent substance emits a certain definite color, yellow for carbon, lavender for potassium, green for copper, and so on, and a mixture of the elements in the sun's atmosphere combines to give white sunlight. Therefore, if a beam of sunlight is split up into its constituent colors by passing it through a prism and they are thrown on a screen, the colors show what incandescent substances are producing them. This is spectrum analysis. During an eclipse of the sun visible in India in 1868 a noted French astronomer discovered some brilliant yellow lines in the spectrum not produced by any element known at that time.

Investigation by him and others proved that it was indeed a new substance, and, appropriately, was christened helium.

Years later traces of it were discovered on the earth. Careful analysis of the air we breathe showed that one part in 245,300 was helium, spectrum analysis proving that it was identical with the element earlier found in the sun. It was also found in certain minerals and mineral waters, but only in very small quantities, held there by occlusion; that is, it was not chemically combined, but held by mechanical means, the same as water in a sponge. So difficult was it to extract, and so rare, that it cost several thousand dollars to produce even a few cubic feet of it.

Perhaps its most interesting use up to the present time is to produce the coldest temperature known to man, namely, 455.8 below zero Fahrenheit. This low temperature was produced by evaporating liquid helium.

Its connection with radium, that magical substance, is worth mentioning, in that it suggests the reason for find-



The R-34, England's greatest airship, was launched from Clydeside. The rear gondola is shown here, giving view of observation glass window and car construction

ing it in natural gas. Silver cannot be changed into gold, so the modern alchemists have told us, basing their argument on the immutability of the elements. True, this has never been done, but it may surprise a lot of men who have not opened a chemistry book since they left college to learn that helium, a chemical element, is produced from radium, another chemical element. Radium is unstable, and decomposes into niton and helium. Niton itself breaks up, and metallic lead (supposedly) is the eventual result. So helium and lead are automatically transmuted from radium. Therefore, it is suggested that the helium in natural gas is a product of the decomposition of the radium held in the bowels of the earth.

Just how fireproof helium is is most strikingly illustrated by a test made by the government. A small balloon was filled with the gas and a blow torch applied to the silk fabric until a hole was burned through. Then the torch was removed, and a most remarkable thing happened. The helium poured out of the hole and quickly suffocated the flames, which were slowly eating the silk and enlarging the hole. Based on this observation, the man who is perhaps the most experienced dirigible pilot of the Navy has suggested that the helium gas in the dirigible bag be used for fire protection throughout the car which hangs from the bag. It could be piped, the same as water, to various points in the car, so that in case a fire broke out a jet of helium would quickly extinguish it.

Let us return to the consideration of the airship itself. Weight is not such an extreme consideration as in the airplane, and, therefore, we can expect to see ships with luxurious saloons, dining rooms, cabins, and the like, green carpeted, and finished in mahogany. There will be a promenade walk the full length of the ship for exercise and observation. Quarters will not be cramped, as they must be in large airplanes now talked of.

The estimated speed of 80 miles per hour is conservative. The big airships of the Zeppelin type, with their enormous bags, drive through the air at 75 miles per hour. Even the relatively small non-rigid type developed by our Navy, with a bag approximately 250 ft. long and 40 ft. in diameter, runs just under a mile a minute with a horsepower development of only 300.

Curiously, the speed rises with the size, so that it is not exaggerating the case to expect that the big air liners will run 80 miles per hour.

To the man who knows how much power it takes to overcome the wind resistance and friction of so small a thing as an automobile, the relatively low power required to project the airship through space is most astonishing —almost uncanny. It requires about 100 horsepower to drive a large touring car along at a rate of 70 miles per hour, and yet the relatively enormous bulk of the Navy dirigible just mentioned requires only three times the power to proceed at nearly the same speed.

The cruising radius of an airship with a 200 to 300-ton

carrying capacity, as already suggested, would be almost unlimited. In this respect it has two advantages over the airplane: Its percentage of weight-carrying ability increases with its size; and the power required, and therefore the fuel needed, is very small compared to an airplane; yet the airship, with its superior carrying ability, has really more room for fuel than the plane. To be specific: The big seaplane mentioned can carry 6½ tons, and requires 1000 horsepower, or 154 horsepower per ton. The big airship, on the other hand, carries 38 tons with a horsepower of 1400, which is used for propulsion only, or a ton for only 36 horsepower. From this simple computation it is plain that it takes about four times as much fuel to transport a ton by airplane as by airship. Or allowing the same space for fuel in two machines of equal carrying capacity, the airship would run four times as far. The speeds of these two machines are roughly the same.

It would be quite possible to build a large airship which would run at its full speed of 80 miles per hour for a whole month, and during that period to circle the earth nearly two and one-half times. Not that any one will ever want to perform such a feat, but it does show the possibilities of the airship. It will be of greatest use in connecting cities separated by vast expanses of water, or land undeveloped by railroads. Its availability to reach the corners of the world quickly is particularly appealing. At the same time it will compete favorably with trains and airplanes, even within the confines of the United States. The trip from New York to Los Angeles might be made in 1¼ days, and shorter distances in relatively less time. Even such a distant point as Melbourne is only 5½ days out from New York; and Buenos Aires, Cape Town, and Hongkong are respectively 2½, 3¼ and 5¼ days.

It seems hardly necessary to point out that the speed of the dirigible is three to six times that of a steamship, twice that of an express train, and equals the speed of a large airplane. Of course, it does not approach the enormous velocities of the small, fast machines, but it is very doubtful whether these extreme speeds of 160 miles or better will ever be attained in commercial passenger-carrying work. Perhaps 120 miles per hour is a fair maximum for fast passenger airplanes. However, it is not so certain but that a dirigible could be made to compete at this speed. With increasing airplane speed, first and operating costs mount rapidly, and at the same time carrying capacity is reduced and frequency with which stops must be made to take on fuel are increased.

It is not the aim of this article to attempt to prove the superiority of the dirigible over the airplane, but to show what the usefulness of the airship is going to be, and to drive home this point it is necessary to compare it with other vehicles of transportation, and airplanes particularly, since competition will be closest between these two.

The Landing Problem

In passing, it is only fair to remark that many thinking people do not look upon the airplane as a future universal means of travel, and there are a large number of aviators, and even some airplane manufacturers, who also hold this view. Lest this statement be misunderstood, let it be added that this does not mean that there will not be many, many airplanes used both for business and sport, but that their number will not be as great as many people like to suppose. After eliminating all other danger factors—fire, derangement of controls, and the like, in order to put the best face on the case—there is still the problem of a *safe* forced landing to be considered, something that may be called for in cross-country flying with even the best imaginable machine. A fence or a ditch, not to mention telegraph poles, trees, and houses, might cause disaster. Landing on the sea is safe except in rough weather.

It is hardly too much to say that a helium-filled dirigible offers at least as safe a mode of travel as a ship. It floats in the air in a manner comparable to a ship on the sea. Its big, rigid bag is divided into bulkheads, so that even a rent in the bag would not affect the buoyancy seriously. It floats at least as securely in the air as a ship upon the water. So, unlike the airplane, the danger of a forced landing is practically eliminated.

There remains the problem of foundering on trees, hills, or buildings. This is a remote possibility, as rare as the foundering of a ship at sea. With present perfection of dirigible control, and knowledge of navigation there is no cause for serious apprehension on this score.

Fog does not present the same danger for the dirigible as it does for the airplane. The former may reduce speed, or stop, but the latter must keep on, at least at its minimum flying speed, which is not less than forty miles per hour, and usually nearer sixty. Nor can fogs always be avoided. Perhaps the greatest danger for the dirigible in a fog will be airplanes, but fog horns should reduce this liability to a minimum.

Wings Cause of Trouble

On the other hand, consider the flying boat. It is hard to conceive of one so large that it will, when forced to land, ride a rough sea with safety. The difficulty lies not in making a seaworthy hull on which to mount the wings and tail. Even the hulls of the present-day flying boats, with lengths of 40 to 60 ft., and beams of 6 or 8, are quite seaworthy *per se*. It is the wings, stretching far out to each side, which cause the trouble, the angry waves battering them until they break up, and with them the whole boat gradually swamps. It is difficult to imagine a flying boat so large that it would be seaworthy in rough weather.

However, assuming that it would resist a rough sea successfully until the necessity for a landing was passed, engine repairs, dense fog, or what not—the man who believes that flying boats will never be forced to land is too optimistic—there is the problem of getting off the rough water into the air again. Skimming the surface of the water at 50 or 60 miles per hour is no joke when it is rough, and even if the boat escapes serious injury there is the certainty of missing teeth or even cracked skulls among the passengers as a result of the rough getaway.

Rising from even a moderately rough sea is a serious matter, as the few naval aviators who have accomplished it will testify.

According to present-day experience, a flying boat which lands in stormy water is doomed. Fortunately, there has usually been a ship near enough to rescue the passengers, but the boat has invariably been lost, unless there was a means for lifting it on board. Towing a flying boat at a greater speed than 4 miles per hour is out of the question; it will not stand up at a higher speed, and yet this is too slow to allow navigation of the rescuing vessel.

Curiously, experiments have just been successfully completed in which a dirigible acts as the rescuing vessel, picking the disabled plane up bodily and carrying it to shore. This expedient was hit upon as a means of rescuing disabled flying boats that would otherwise be lost.

It is argued that the multi-engined plane of the future should never be forced to land, inasmuch as it is not likely that more than one engine will refuse to run at

one time. But this view is debatable, although there is not space to discuss its technicalities here.

No comparison of fire hazards in airplanes and airships is attempted, because the indications are that these will presently be practically eliminated in both.

Docking of a big airship presents some difficulties, but with the special facilities which must certainly be developed it should offer no more risk than bringing a large ocean liner to its berth.

From the standpoint of comfort, the roomier airship should prove preferable to the airplane. As to steadiness, the advantage, if any, is in favor of the plane, the air liner having a tendency to roll and pitch. Engine noise should be less in the dirigible; in fact, there is no reason why it should be greater than in the modern automobile, for high power and low weight can be subordinated to quietness, and the engines may be well muffled. The difficulty in quieting an airplane engine lies not in the extra weight and wind resistance of the mufflers, but in the fact that their presence reduces the possible power output, not directly by causing back pressure, as in the automobile, but by producing valve trouble. So it is a safe conclusion that the dirigible will be much quieter than the airplane.

The dirigible will offer a better view of the land underneath, since it can be operated with safety at a low level—1000 ft. is about right for the best view—while the airplane will soar at 5000 ft. so as to increase its gliding radius and allow a large choice of landing places in case of an urgent landing.

There seems to be no limit to the size of a dirigible but there is a limit to the size of the airplane, if the word of F. W. Lanchester, a noted English authority, may be accepted. Various considerations fix the maximum wing span at 160 ft., and there are also limits to the depth of the wings and to their number.

The weight-carrying capacity of the airship increases with the size, while the weight-carrying capacity of the airplane remains constant at about 33 per cent. It is estimated that large dirigibles will be able to carry a useful load of 70 to 75 per cent of their total lifting capacity, and even the large machines of to-day carry 60 per cent pay load.

Helium-Filled Dirigibles Logical for Commercial Use

The cost of an airship is, of course, many times that of a large airplane, but in comparison with a large airplane there is little difference, the cost per ton useful load being about the same.

So, viewing the matter from every angle, it is reasonable to expect to see large fleets of helium-filled dirigibles carrying passengers, valuable freight and mail to the far corners of the earth, speeding up intercourse at such an enormous rate that commerce and the march of civilization, interlinked, will grow far beyond the dreams of even the most ardent champions of aerial transportation.

The military use of the helium dirigible is particularly attractive. Its size and ample weight-carrying capacity permit it to carry an enormous number of bombs for use against submarines, particularly, but also for night bombing. It will also undoubtedly be of service in bombing enemy war vessels when used in connection with fighting planes, and perhaps also war vessels working in conjunction with it.

It will undoubtedly be equipped with small caliber guns for offensive use on both land and sea.

It will be invulnerable to enemy airplanes except against bomb attack. The weakness of the dirigible heretofore has lain mainly in the inflammability of the gas used in the bag, a few well-placed incendiary bullets quickly setting the machine in flames and destroying it, but with a non-inflammable gas, machine-gun fire will have practically no effect. The enormous bag might be fairly riddled with holes without causing a serious loss of gas. By armoring the vital parts, such as the engines, machine-gun fire would have little effect on the operating mechanism.

All of this is assuming that an airplane would dare venture near this new aerial monster. But with numerous machine guns and small-caliber guns for defense, it is doubtful whether any airplane would accept the risk. This circumstance is perhaps best illustrated by the experience of the British with the enormous flying boats which they used for submarine patrol work in the North Sea. These boats carried several men, had a wing spread of about 100 ft., and were equipped with two large Rolls-Royce engines. When first put into service some were lost in unequal combat with several fast enemy planes, the big boat being too slow to run away and being insufficiently armed to put up a fight. Presently, however, these big boats were armed with twenty machine guns, in pairs, and soon after one of them was sighted by a squadron of ten enemy planes. As is customary, it descended close to the water, so that it could not be sought from its blind spot under the large hull, and waited for the attack. The fight was soon over, for its twenty machine guns quickly accounted for all ten planes. Due to the total destruction of the enemy force, no inkling of what happened to the squadron reached enemy headquarters, with the result that shortly thereafter another squadron of ten appeared over the sea and gave battle to another one of these big boats which had formerly been such easy prey. One lone machine escaped from the fray and straggled back to Germany with the news. After that, enemy squadrons were very careful about attacking large flying boats until they had determined the power of the armament.

The point is obvious. If a large airplane is so nearly invulnerable against machine-gun fire of enemy planes, how much more so would the big dirigible be, with opportunity to install almost any number of guns with which to bring them down or ward them off? Even if an attacking machine did weather the storm of lead hurled against its practically defenseless and exceedingly vulnerable structure, and came close enough to insure accurate shooting, it is doubtful whether it could do any damage worth considering.

It may be objected that the monster airplane would at least be the equal of the air battleship, but the enormously greater carrying capacity of the latter would always permit a preponderously superior armament. Nor would the big airplane possess a tactical advantage because of greater speed, because the airship can at least equal it in this regard.

The big aerial warship is therefore an exceedingly formidable weapon, and has nothing to fear seriously as long as it keeps out of range of anti-aircraft guns on land and sea. It is quite certain that the navies of the future will have large numbers of these craft for offense, defense and observation.

Michigan Carries $50,000,000 Good Roads Bonds

MICHIGAN voted overwhelmingly in favor of the $50,000,000 good roads bond issue, the project carrying in nearly every precinct by a 4 to 1 vote. The campaign for the good roads movement was directed by the Michigan State Highway Association, backed by every automobile club and chamber of commerce in the State.

The project authorizes the State to borrow for the improvement of highways and to issue bonds not to exceed $50,000,000. It provides that counties bear from 10 to 60 per cent of the cost.

Review of English Labor Conditions

Trade Union-Manufacturer Agreements — Shop Steward System — District Allied Trades Council

REASONS FOR PRESENT LABOR UNREST INDICATED

By Harry Tipper

IN view of the reports which have just been made public, of the commission which was appointed to deal with the dispute between the coal miners, the owners and the Government and the general industrial commission, it is important that the background for the situation in Great Britain should be understood.

It is obvious that the results of these congresses of capital, labor and Government together, in Great Britain, will have considerable bearing upon the situation as it develops in this country, although the conditions are so different in that country that the methods adopted there would not be of immediate value in our considerations here.

The wide discussion which these measures are causing and the enthusiasm which they are creating in a good many quarters, where the difference in background is not understood, make it all the more important that the same consideration should be given to the conditions out of which these triangular agreements, or decisions, have arisen.

The custom of making agreements between the manufacturers individually, or in groups, and the trade unions interested in those manufacturing operations, is an old one in Great Britain. For at least twenty years there have been agreements between the engineering trades and the trade unions concerned in these special operations, which involve the question of shop committees and which involve the system out of which has grown the shop steward arrangement.

Union Agreements Made 35 Years Ago

The union has been accepted as a necessary means of arriving at arrangements in Great Britain during a period of from twenty to thirty-five years in the different lines of industry. For that reason, the question of the merit of collective bargaining in this way and of agreement upon matters of hours and wages, etc., through the trade union, in Great Britain, does not enter into the discussion. This historical background of usual practice in dealing with the local trade union and the national body in arriving at agreements upon matters affecting the workers has led logically to the situation which is indicated by the triangular conferences between labor, capital and Government as they exist to-day in Great Britain.

It is now some thirty years since the Labor Party, as such, entered into politics in Great Britain actively as a party. Originally this party began with the desire of the trade unions, or the workers, to be represented in the Parliamentary discussions, and the first representatives in Parliament were paid by the trade unions because there was, at that time, no payment of Parliamentary members by the Government. The writer recalls very well the meetings which occurred when the workers of the Lancashire district decided to secure representation in Parliament.

In the course of time the Labor Party as a political body, because of the similarity between its aims and the necessities of a good many of the smaller professional and other types of independent workers, extended itself and secured support from the small shopkeeper, the office worker, the professional class and the other brain workers to a very considerable extent. As a consequence, the influence of the Labor Party has grown out way beyond the original conception of the trade unions in desiring Parliamentary representation and has brought into the platforms of the Labor Party, as a political organization, a great many questions with which the trade union, as such, was not particularly concerned. In the meantime the growth in public power, through the organization of the Labor Party as a political entity, has strengthened the hands of the trade union in extending the organization of other workers into the ranks of the trade unions and in federating the different unions for purposes of organization upon public matters. Furthermore, the practice which began twenty or thirty years ago, of deciding such industrial questions as wages, hours and labor production and methods of operation, through the trade union, itself increased the power of the trade unions and the advisability of all workers aligning themselves with the unions. These considerations meant that at the beginning of the war the industrial workers in Great Britain were organized to the extent of a majority of the workers in the most important industries and in many industries almost exclusively so organized.

When the war broke out it was necessary for the Government, in its preparations to meet the enormous tasks imposed upon the country by the necessities of the war, to use this organized machinery of the workers to provide the means of selecting the essential workers, of diluting labor and of obtaining a more or less smooth and efficient continuance of operations. This was recognized by the Ministry of

Munitions, but the usual inefficiency of the Governmental bodies affected the results so that there was continual cause for dissatisfaction on the part of both workers and manufacturers, and these unsatisfactory methods of procedure were largely responsible for the number of strikes which occurred during the war period in that country.

For instance, the question of naming the essential individual workers and issuing cards to them was at first left in the hands of the local trade unions with the obvious result that great abuses crept in, producing dissatisfaction among the workers, trouble with production, and without properly accomplishing the purpose. This method was changed before very long and the method was adopted which was continued through the rest of the period.

In order to secure the adherence of the trade union organizations to the immediate purposes of the Government in prosecuting the war, it was necessary for the Government to promise these organizations that the privileges which they voluntarily abandoned should be restored to them when the war was over. It is due largely to the difficulty of restoring these privileges at once that the unrest occurred which has resulted in the conferences that have just closed.

A very discerning British manufacturer, with whom we have had the pleasure of talking just a little while ago, made the statement that the labor organizations, as such, were just revelling in their first knowledge of controlling power, and when they had been obliged to shoulder the responsibility which goes with such power, for a sufficient period of time, the situation would develop into satisfactory compromises.

Not only is the power of labor thoroughly organized and recognized in the discussion of labor questions so that treatment between labor organization and manufacturer has become the usual practice, but well defined systems of conference have grown around this power, which vary in practice from the systems that have been adopted in the United States and which lead to an entirely different necessity in present negotiations and those of the immediate future.

The shop steward system in England is one which has been in use for about twenty years and which has grown into a complete system in about the last ten years. The shop steward is the liaison between the workers in a department and the foreman. If the rules as expressed in the agreement between the trade union and the manufacturer are not lived up to, he can carry his grievance to the management. Collectively the shop stewards in a plant form a workers' committee, inasmuch as they are appointed by the workers in each department and are paid by the workers for the time which they must spend upon their shop steward duties. Together with the representatives of the managers they form a conference committee, and this practice has obtained in the engineering and some of the other industries for a number of years. While these shop stewards, together with the management, form a conference plan or joint shop committee, this whole system is bound by and affiliated with the trade union and the manufacturer's group, so that it must operate within the agreement between the union as a body and the manufacturer and be subsidiary to such an agreement.

It is not in itself, therefore, a complete system of co-operative responsibility in connection with the individual factory or manufacturing unit, but simply provides working machinery in the individual manufacturing unit whereby the decisions and agreements arrived at between the trade union and the manufacturer can be kept in orderly operation. The growth of the shop steward system, leading to this conference plan affiliated with the unions, has led to the formation of what is termed the District Allied Trades Council, which consists of representatives of each union in the district in alliance, for the purpose of keeping the district in uniform practice in respect of matters relating to wages, hours and working conditions. This District Allied Trades Council is the bone of contention between the manufacturer and the union organization and has been the seat of revolt against the federated trade union on many occasions during the war and afterwards. In other words, the District Allied Trades Council has secured by its organization sufficient power in its local district to take the power away from the central organization and threaten to disturb the traditional method of agreement between the nationally organized union and the manufacturer's group. Furthermore, this District Allied Trades Council follows the local demand for action much more quickly and much more definitely than the centralized body and is apt to favor the radical demand, which gives more hope of satisfying their immediate constituency in their desire for action rather than deep consideration.

Intensive Force of English Organized Labor

When it is understood that this general condition in the industrial fields in Great Britain is coupled with the desires of a class of great solidarity, homogeneous in its growth, permeated with pretty much the same ideals and the same political outlook, the intensive force of organized labor and its great influence upon the future development of Great Britain politically and economically can be understood.

Great Britain is the oldest machinery manufacturing country in Western civilization. Its generations of workers have worked upon the same line of work from one to the next generation. They have lived in the same towns, they have been imbued with the same ideals, intensified by their definition and application and the homogeneous character of the people. It is for this reason that co-operative societies, organized by workers, have had such a large success in that country, and it is for this reason that profit sharing has made so little headway. These differences need to be thoroughly understood in this country if the developments which are taking place on the other side are to be understood properly in respect of their applicability to our problems and the modifications which must arise in our methods due to the difference in the conditions.

Turning Out 100 Tractors Per Day

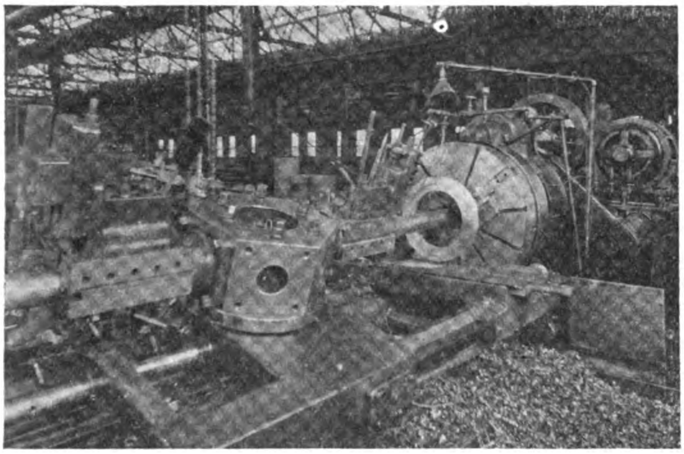
PART II

Production System Employed at the Milwaukee Plant of the International Harvester Co.—Details of Machining and Assembling Methods

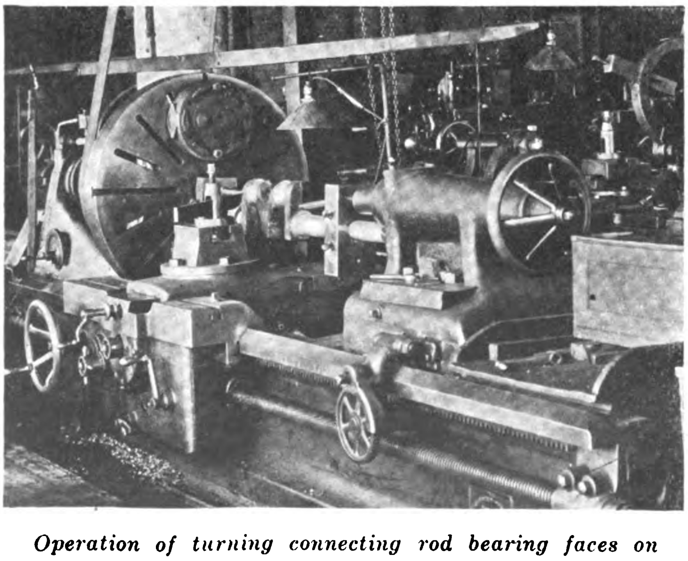
By P. M. Heldt

MOST of the fifth floor of the International Harvester Co. is devoted to the manufacture of piston rings. These are made from the usual cast-iron pots, and are of the eccentric type. Boring out the pot, turning off the outside eccentrically and cutting off the rings are performed in one setting. The lathe carriage carries the boring tool; the turning tool has a sliding mount and is moved back and forth by means of an eccentric pin, and the rings are cut off by means of a multiple cutting tool on the back of the lathe which is fed in toward the axis of the spindle as the carriage with the boring and turning tools progresses toward the lathe head. The cutting-off tools, of course, are so set that the outermost ring is detached first, then the next, and so on, so that the boring and turning operations on any ring are always completed before it is cut off.

All keyways are cut by broaching, and the broaching process is very extensively used in the plant. For instance, all sliding gears are bored out, and then have a square hole broached. All of the small gear blanks are finished in double spindle turret lathes. The small bevel gears are cut on three spindle cutters and the large bevel gears on two spindle cutters. The reverse gears are cut on three spindle machines, six gears being put together on an arbor and cut at the same time. Every gear is tested for trueness on a special testing machine. The broaching and gear cutting work here described are also done on the fifth floor.



One of the large turret lathes



Operation of turning connecting rod bearing faces on the crankshaft

On the fourth floor there is a miscellaneous collection of machine tools, including drills, lathes, etc. Here the steering knuckles are machined up. These are drop forgings, and are subjected to a heat treatment which increases their scleroscope hardness from 28 to 45. In order to provide a proper surface for the rollers of the roller bearings to roll on after the heat treatment, the knuckle is straightened in a straightening press, and is then tested by means of a dial gage.

Practically the whole of the third floor is devoted to tool making, making of dies for sheet steel work, and to tool service.

A platform has been erected in the yard, level with the second floor of the machine shop, so that castings from the foundry which are intended for the second floor of the machine shop can be deposited on this platform by means of the outside crane, and then transferred directly to the second floor of the shop, thus obviating unnecessary congestion of the main floor. Metal shavings from the machine shop are loaded on to cars in the yard in the same way.

Finishing the Crankshafts

On this floor the crankshafts are finished up. Owing to the motor being a two-cylinder machine, the crankshaft is comparatively simple, but a number of interesting machining operations have been evolved. Thus two crankshafts are milled at the same time for counterweights. The crankshafts are drilled for oil delivery to the crank pin bearings. Both ends of the crankshaft forgings are sawed off in power hack saws at the same time, and then center-drilled at the same time. In order to conserve human energy as much as possible, a monorail is installed under the ceiling of this floor, and all crankshafts are handled by blocks and tackle in transferring them from one machine to another. The camshafts are also turned up and ground in this department. The crankshafts are rough turned, finish-turned and ground, and very fine limits must be worked to, as the tolerances on the crank pin are + 0.0005 in. and — 0.001 in. A lapping tool of the nut cracker type is sometimes used, if it happens that a pin or main bearing is very close to the proper size. The camshafts are rough-machined on the round portion and the cams are rough ground, after which the shaft is heat treated. Then the whole is finish-ground.

On the ground floor there are miscellaneous machine tools, including key-way cutters, lathes, drill presses, etc. Both ends of the connecting-rods are bored out at the same time, and after boring they are reamed at the same time. The rods are next put into the milling machine and have the caps cut off and the lugs milled. At this setting, one slitting and two surfacing operations are performed at each end. Flywheels are turned up in a vertical lathe, and are balanced on a static balancing machine. By means of a horizontal mul-

General view of the main assembly room of the International Harvester Co. Here assembly of the clutch, flywheel, pistons, connecting rods, oil leads, muffler, etc., is carried on in the aisles under the balconies. The tractors are then moved around the ends into the main aisle, where the assembly operations are completed

tiple spindle drill, holes are drilled in the flywheel arms for the bolts by means of which the friction clutch pulley is secured to the flywheel. In drilling these holes, the flywheel is centered on the tail stock and a template is used in locating the holes. The friction clutch pulleys are turned up in a heavy turret lathe.

All heavy work is done in the main machine shop, which has one center aisle and two side aisles. Three overhead cranes run on a craneway extending the whole length of the building. Each heavy machine tool has its own air hoist on an arm swinging from a post. In this department there are many heavy continuous millers, as well as large boring machines and drills. Both sides of the crankcase are face-ground on a diamond face miller. The cylinder blocks are milled off at both ends and at the top, in an Ingersoll continuous milling machine in one setting. There are four Foote-Burt two spindle boring machines for boring and reaming crankcases in one setting. A radial drill press is used for spot-facing the surface around the bolt holes of the crankcase on the inside. Four Baush multiple spindle drill presses are installed for drilling and tapping all of the holes in the crankcase, using a jig for locating the holes. Next there are two large continuous millers, one for milling the crankcase, the other for milling the lower half of the transmission case. The former operates with four cutters, of which two are arranged vertically and two horizontally. Many of these machines are fitted with turntables, so that the machine can be loaded at the same time that it is working.

An interesting method is employed for moving the flywheels over the floor. A steel tube is put through five of these flywheels and then a bent bar, forming a handle, is hooked into the ends of the steel tube, whereupon it is possible to roll the flywheels over the floor, the same as a wheelbarrow.

A horizontal milling machine is used for facing the bearing slots in the crankcase. and six of the cases are clamped on the carriage of the machine at the same time. Another continuous miller, with six cutters, operates on two rows of crankcases (8 in all) facing off the top surface and the surface to which the cylinders bolt. A number of other continuous millers are used to finish the frame support faces on the upper half of the transmission case, the cases on each machine being strapped on the carriage in two rows, and the machine being provided with four cutters.

Boring and Milling Operations

After the transmission case halves have been fitted together, the ends of the bearing hubs are milled off, three cases being placed in the machine at one time. There is also in this department a battery of eight boring mills for boring and facing operations on the flywheel, and facing the lower half of the crankcase. A double-ended boring mill serves to bore in one operation the bearing hubs at each end of the transmission case and the reverse gear eccentric shaft holes. The holes in the crankcase are drilled in a multiple spindle drill, and another similar machine serves for tapping these holes.

The holes for bolting the driving sprocket wheels in place are drilled in a multiple spindle drill. Then the wheel blanks go on to an automatic gear cutter that finishes the sprocket

teeth in one operation. Both sprocket wheels on each tractor are interchangeable, there being no rights and lefts. There are four of the automatic gear cutters working on driving wheels.

Pistons are made in one of the galleries. The first operation is to face the open end in a turret lathe, and all subsequent work is located from this machined surface. Next, the piston goes into the drill press for boring the piston pin hole. It is then put into a Potter & Johnston lathe for roughing the outside surface, the top surface and the ring grooves, and then into another one for finish cutting. Next, oil holes are drilled through the piston wall, and the hole for the piston pin set screw is drilled and tapped at the same time. Holes are also drilled for pins for the piston rings. These pins are located one-half in the groove and one-half in the solid metal, and after they have been screwed tight, they are cut off with a hacksaw. After the final grinding of the piston, these pins are slightly relieved by means of a file, so that they will not project above the surface of the piston when the latter is hot, owing to the greater expansion of steel as compared with cast iron. After the pistons have been rough-ground, they are set aside for a while, which gives them a chance to age or relieve themselves of internal strains, after which they are finish-ground on the same machine. The final grinding of the pistons has to be held within limits of + 0.001 and — 0.001 in. Next, the cross hole is finish-bored and reamed in a lathe. A special clamping jig is used for holding the piston to the face plate of the lathe, and there is a taper centering pin on the turret for squaring the piston in the jig.

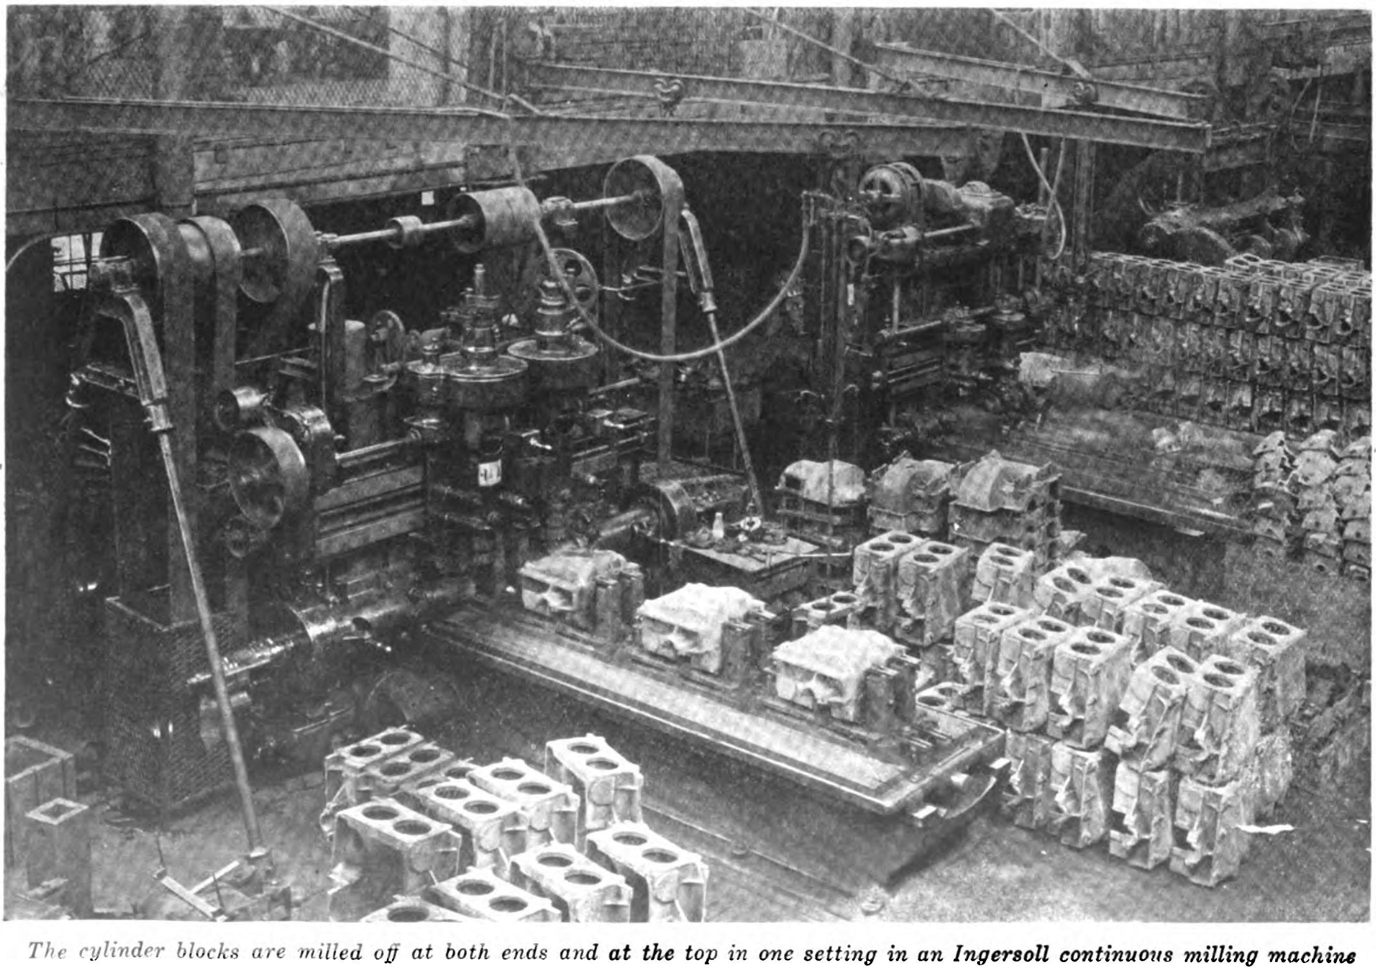
The cylinder blocks are bored and reamed, and the upper edge of the cylinder bore is beveled out so that the piston and rings will enter readily. This operation, performed in a double spindle vertical boring mill, is shown in one of the illustrations. All cylinder and cylinder head castings are given a water pressure test. The water enters the casting through a hose at the bottom; then air under a pressure of 120 lb. to the square inch is applied through a hose at the top. This method has the advantage that one test suffices to show any leakage through either the inside or the outside wall. The cylinder head flange holes are drilled in a multiple spindle drill with 11 spindles. This drill is also provided with a turntable, so that it can be loaded and worked at the same time. The drills are self-feeding, and the operator can devote all his attention to the loading of the fixture. A similar plan is used in drilling the crankcase, this being performed in two operations, four holes being drilled in the first, and five holes in the second operation in the same drill. The holes in the sides of the crankcase are drilled and tapped in single spindle drills.

In one of the galleries of the machine shop, the transmission bearings are babbitted and broached. This broaching operation includes a compacting operation, an arbor with a very small taper being forced through the babbitted bearings. Oil grooves are provided for in the arbor, and do not have to be cut specially. This compacting arbor compacts and smooths the surface of the bearing and imparts to it greater wearing qualities. The arbor is split lengthwise, at a slight angle, so that there is no difficuly in withdrawing it from the bearing after the operation is completed.

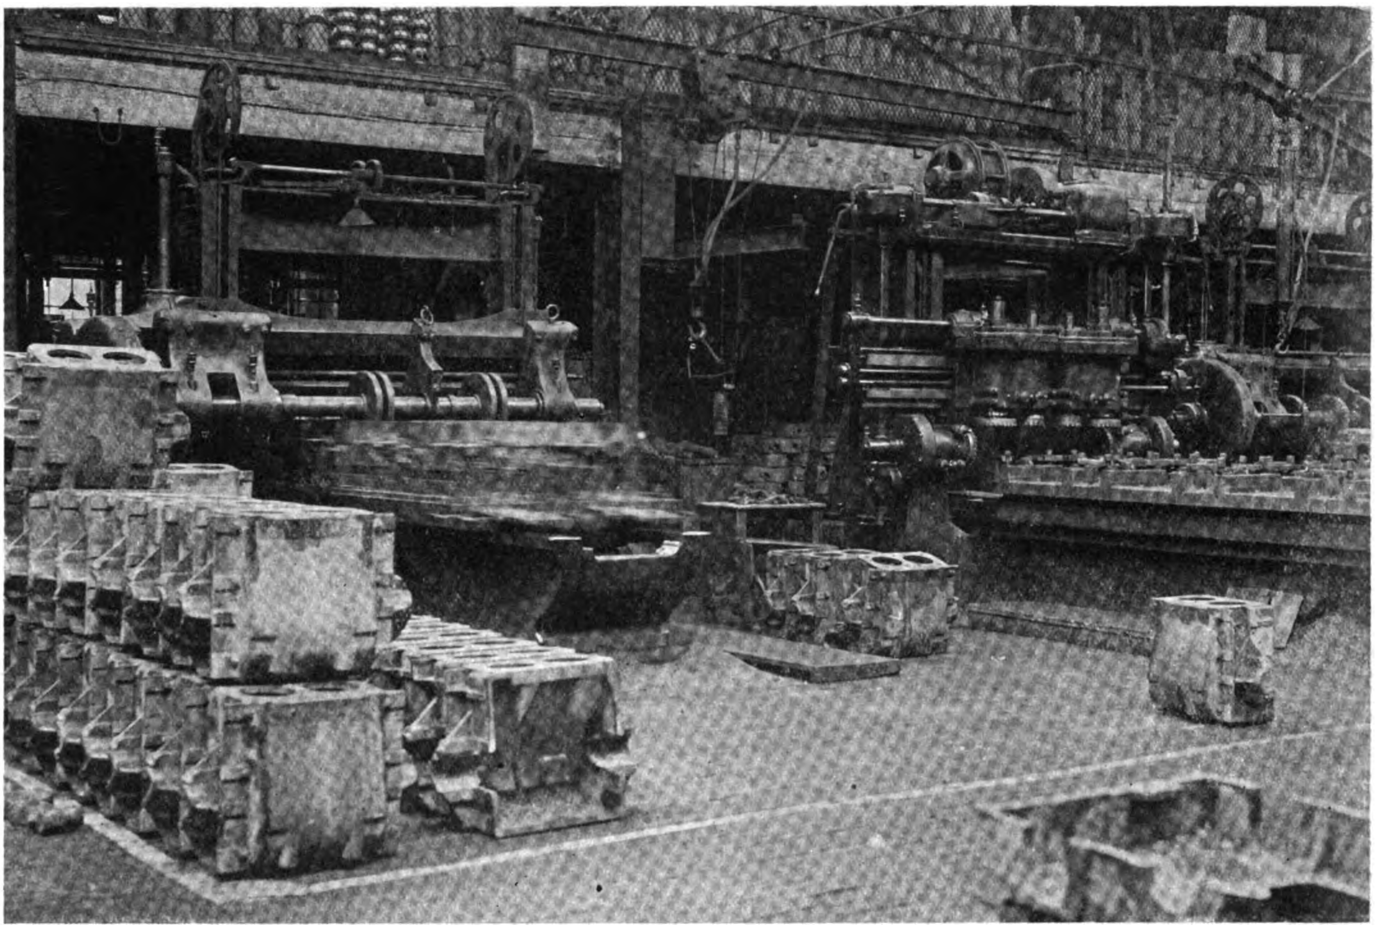
The Brass Foundry

The plant also has a brass foundry, although not a great many brass castings are used in tractors. All brass shavings are recovered in a separator, which works on the magnetic principle. The shavings are fed on to an inclined shaker, over which is passed a revolving multiple electromagnet. As the magnets pass over the shaker, at a short distance, they pick up all magnetic shavings (iron and steel) and carry them along, and as soon as they are beyond the shaker, they are demagnetized and then drop the magnetic shavings into a collector.

In the carbonizing room there are 23 furnaces for carbonizing such parts as the small sprocket, camshaft, valve push rods, cam rollers and valve rods. The connecting-rod bolts, which are made of special material, are heated in a barrel furnace for heat treatment. A recording pyrometer is in-



The cylinder blocks are milled off at both ends and at the top in one setting in an Ingersoll continuous milling machine



Both sides of the crankcase are face-ground on a diamond face milling machine

stalled in the foreman's office, and records the temperature of everyone of the furnaces, being automatically switched into circuit with the thermo-couples of the different furnaces, at intervals of one minute. This pyrometer, as stated, is of the recording type, and the records from it are sent to the assistant superintendent every day. The record is burned into the record sheet by means of electric sparks, passing from the point of the indicator arm to the drum on which the record sheet is mounted. All furnaces in the works are heated by crude oil. It should also be pointed out that all of the heavy machine tools are driven by independent electric motors.

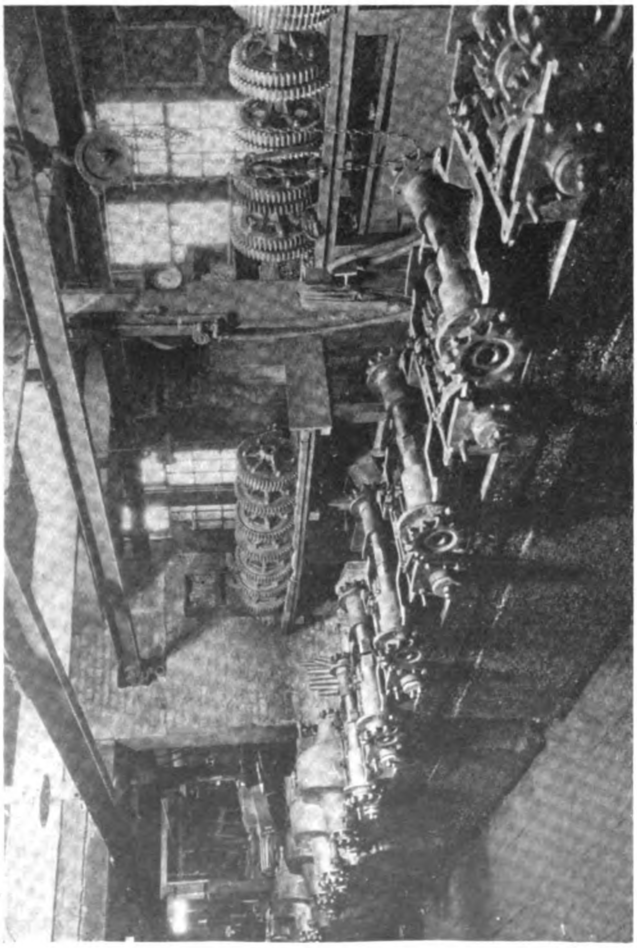
In the assembling department the so-called progressive system is used. First the frame, which is made of steel channels that are bent to form while at a red heat, are assembled with the rear axle housing and the front bolster in a jig, and riveted together. The use of this jig insures that the frame will be square. Next, the frames are placed on three caster wheels, which facilitate their movement over the floor. Each unit is brought assembled to the main line of assembly. A good example of the assembly of components is furnished by the transmission, which is assembled on the progressive plan. The transmission cases are slid along a pair of rails, at a convenient height above the floor for the workman to work upon. The low and high speed ring gears and the differential gear have been assembled previously, and come to the transmission assembly line in the form of a complete unit. An overhead monorail over the differential assembling bench delivers these units to the transmission assembly line and also serves to move the complete transmission to the main line of assembly.

The first part of the assembling work is done in what is referred to as the truck shed. When the tractor frame leaves this shed, the transmission, rear axle, gear shift mechanism and part of the steering gear (the worm and sector) are in place. In the next building, which is the main assembling room, the crankcase is put on and then the crankcase bearings are put in place. These bearings are given a double reaming, which is done by means of air tools. On a side line, oil rings and the counterweights are put on the crankshaft and the crankshafts are balanced. Then on the main line the crankshafts are put into the engine. The next assembling operation is to put on the clutch, clutch wheel and flywheel. Each end of the crankshaft is center-drilled and screw threaded, and these screw threads serve as an anchorage in forcing the flywheel and clutch onto the crankshaft. All of the heavier operations and many of the lighter ones in the assembly are performed by means of air tools. This greatly expedites the work, and obviates fatigue of the workman. Next, the keys are fitted, and the gear shields for the countershaft put on. The next operation consists in putting the cylinders onto the crankcase, the studs having been put into the cylinder block on a side line. All studs are put in place by means of air tools. A jig is used for centering the cylinders with the crank pins, the cylinder flange holes being made slightly larger to permit of this adjustment.

Assembling Piston Rings and Connecting-Rods

On a side bench the piston rings are put on the pistons and the connecting-rods are put in. These complete assemblies of pistons and rods are brought up to the main line at the proper place, where they go on to the chassis. Next, the oiler and oil leads are put on. The cylinder heads, with the valves, tappet arms and studs, are assembled at a side bench, and at the same point on the main line are put on to the engine. Next, the muffler is put on. At this point, the engine is subjected to a low pressure water test (30-40 lb. per square inch) to test the water tightness of the gasket.

All operations described so far are performed on a side aisle under the balcony. The chassis now having reached the end of this aisle, is turned around and enters the main aisle, and here is moved along by an overhead crane. Through the main aisle the chassis move in three parallel lines. Here the crankcase covers, with the governor, camshaft, push rods and guides, which have been assembled on another bench, are



Transmissions are progressively assembled on rails, the finished product passing to the main assembly room

After final inspection the engine is submitted to a Prony brake test and operated at 500 r p.m. under various loads for 30 min.

put on to the engine. The crankcase covers are assembled in one of the galleries, and are brought down on trucks on an elevator. At this point also the valves are timed and the magneto is set. While this is being done, other minor parts are added, such as the seat and spring, steering wheel, mixer, fuel tank and piping, governor rod and bracket, air cleaner, air pipe and water piping. All these parts are stacked up at the side of the main line of assembly opposite the particular point where they go on to the chassis.

When all these parts have been fitted, the mounting gang takes hold. They put on the front wheels, the front axle, the driving chains and steering rod, all at the same point. Then another gang puts on the water tank and connections. At the same time that the wheel shields are put on, the engine is being filled with kerosene, oil and grease. The water is delivered to the tank through a hose, which depends from a water box mounted overhead. This box is fitted with a flushing valve and all the operator has to do is to insert the end of the hose into the filling hole of the tank, pull a line connected to the valve, and the proper amount of water to fill the system will be released. The grease reservoirs are filled by means of hand grease guns, and fuel is pumped into the fuel tank by means of a measuring fuel pump.

This completes the assembly operations, and a man from the test floor now takes charge of the tractor. He primes the engine with motor spirit, and starts it with a hand crank, which operation usually succeeds at one of the first trials. Then the tractor is driven across the yard to the test floor under its own power. As more than a hundred tractors are turned out every working day, this performance is repeated every six minutes.

On the testing floor the engine is first given a 1½ to 2 hr. idling test, to limber up its moving parts. At the end of this test the connecting-rod bearing caps are removed and the bearings are inspected to make sure that they are in perfect condition. Also, the valve timing is checked over and the magneto timing and wiring is inspected. The mixer is looked over to see that its valve is set properly.

Next the engine is submitted to a Prony brake test, the ordinary water-cooled Prony brake being used. The engine is started up and its speed adjusted to 500 r.p.m., after which it is given a 30 min. variable load test. Having satisfactorily withstood this test, it is run for an hour under 20 per cent overload. After this period, the engine is given a final inspection by the test floor foreman. He removes the crankcase cover, and feels the bearings to detect any possible overheating. The tractor having satisfactorily passed this final test, it is delivered to the paint shop.

There are about 50 tractors under test at the same time on the test floor, and each tractor remains in this department for about 8 hr.

Painting is done entirely by hand, and each tractor is given two coats. As soon as the paint is dry, the tractors are loaded on platform cars or put into storage. They are driven onto the cars under their own power.

Box Handles of Webbing Save Space

IN export shipment, boxes loaded with 200 to 300 pounds are most easily manipulated when provided with handles. Usually such box handles are made of rope, inserted through holes in the ends of the box and secured with wall knots, or inserted in grooves on the under sides of the cleats on the ends of the box and held in place by nails or screws driven through the cleats.

A box handle made of webbing instead of rope has been suggested by the Forest Products Laboratory as a means of conserving space. For this purpose webbing about ⅛ in. thick and 1⅛ in. wide, which has a breaking strength of 800 lb., should prove suitable.

A New Shop Accounting System

As Installed by the Tractor Branch of the Moline Plow Co.—Gives at All Times a Correct Record of the Situation in the Plant with Respect to Raw Materials and Finished Parts

IN order that a production schedule may run ahead smoothly, it is necessary that all parts required for the complete product, whether manufactured directly in the plant or obtained from outside sources, be always kept on hand in sufficient quantity to allow of assembling work going on unhindered. To insure this regular supply of parts, most large plants have a stock accounting or stock chasing department, the duty of which is to keep an accurate record of the stocks of all parts on hand and to issue a warning when the supply of any one part runs low. A special system for accomplishing this object has been worked out and applied by the tractor branch of the Moline Plow Co. and has proved most satisfactory.

Each department is provided with a schedule which covers the various items on which that department does any work, showing what quantity it is necessary to produce each day. These schedules are made up a whole month in advance. As the parts are produced, the production figures are posted on the schedule. When production of a part is up to or runs ahead of the schedule, the figures are posted in black, otherwise they are posted in red ink. Figures regarding parts that are not made in the factory, but obtained from outside sources are posted from the receiving slips made out when the parts come in.

The master sheets are kept in the Production Department, but duplicates of the sheets are sent to the respective factory departments. There are six departments for which duplicate sheets are made out, namely:

1. Purchasing department.
2. Foundry.
3. Forge shop.
4. Grinding and snagging.
5. Machine shop A.
6. Machine shop B.

A master sheet is made out for each department. Each of these sheets contains columns for the parts, numbers and names of all parts which the particular department handles.

Then follows a column in which are entered the numbers of parts required per month, and then another column in which the numbers required per day are entered. At the beginning of the month there are entered upon the sheets the numbers of all parts on hand, the total numbers required for the month, and the requirements per day, the latter figures being extended across the sheet. Production data are entered upon the sheet in cumulative figures, in black or red, according to whether production runs ahead or behind schedule.

The product of each department goes through the hands of inspectors, and all inspectors make a daily report to the Production Department. One of these inspector's blanks is shown herewith. Red and blue buttons are used to indicate a dangerous shortage in the amount of stock on hand, which is figured in terms of number of days' supply. When the stock of any particular part runs low, a red button is placed on the sheet to indicate the day on which the supply, if not replenished, would run out. Blue buttons are used when the supply of parts runs low, but will last into the following month, in which case it is necessary to post the button in one of the first columns of the sheet. The blue button really indicates that the date to which the supply on hand lasts is in the following month. When new stock is received, the buttons are moved. One man does all the posting, and spends only about one-half of his time at it.

Weekly Check Up of Scrapped Material

At the end of every week, pieces that have been scrapped and parts that have been sent out for repairs are checked off. At the end of every month the man having charge of the accounting system takes the stock on hand at the beginning of the month, adds the number of parts produced during the month, subtracts the number of parts used in manufacturing operations, the number of parts scrapped, and the number of parts sent out for repair purposes, and the remainder is the stock on hand at the beginning of the next month.

The schedule here described acts as a shop order, and also as a stock record. The Moline Plow Co., in its tractor department, issues no special shop orders for any parts manufactured in its own plant, the schedule of the Production Department serving this purpose.

Sources of Production Sheet Data

The form herewith serves for collecting the data which are entered on the production sheets. All product completed by any department of the works passes through the hands of inspectors and the inspectors' reports are sent to the production department. Similarly when material purchased by the company arrives at the factory it is checked up by the receiving department and the report made out is sent to the production department.

Airplane view of Motor Reconstruction Park

M. T. C. Salvage Park in France

PART I.

An American War Factory in the Heart of France—3500 Employees—Built in 65 Days—Was 120 Miles Behind Front—Engine Department Overhauls 100 Engines Per Week—1000 Jobs Weekly Output—Manufactures New Parts

By W. F. Bradley*

PARIS, Feb. 11—Early in May, 1918, a staff of Motor Transport Corps, U. S. A., officers and mechanics was put in possession of 337 acres of agricultural land in the center of France and told to erect on it a main salvage and reconstruction park capable of taking care of all the wreckage then accumulated from the front, and to provide for the huge quantity bound to come with the summer fighting.

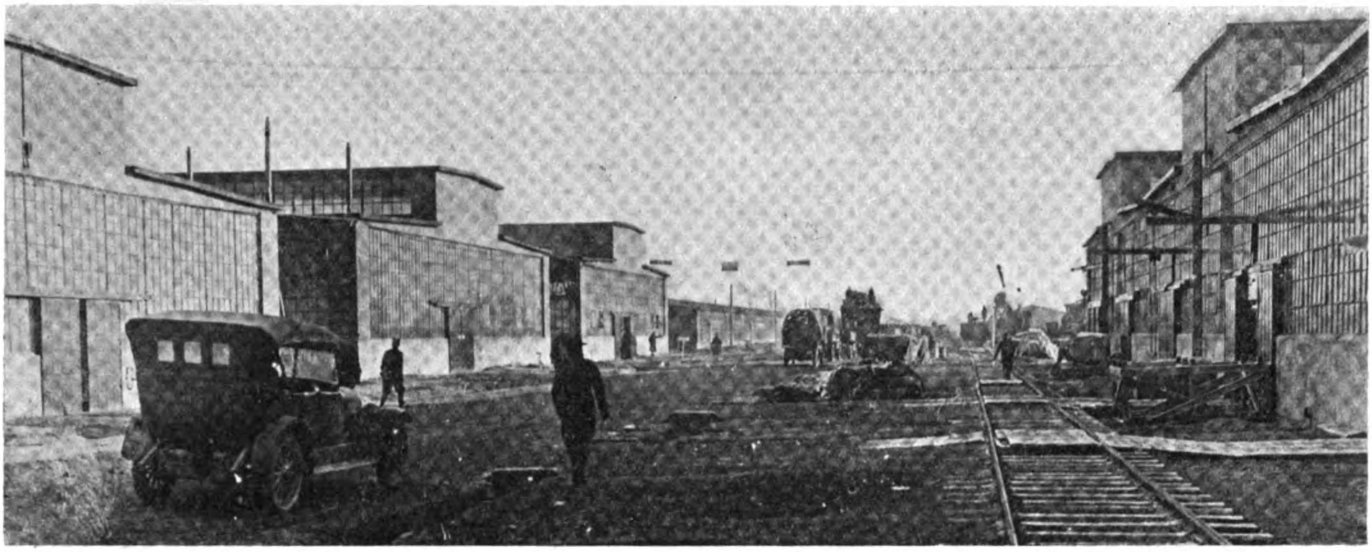
The first task of the M. T. C. men was to drive the cows off the land, then to erect buildings, and, as each one was completed, to appoint a staff and start production. The ground was purely pastoral. A railroad ran through it, and the nearest village comprised a score of houses. The 3500 men put on this job brought all the material, with the exception of some lime and stone. They prepared their own plans. They cleared and drained the land. They erected the buildings and installed machinery, and on July 15, or only 67 days after taking possession of the bare land, moved into the shops. Fifteen days later they were in production.

5300 Busy Workers

When I visited this reconstruction park in November, 1918, there were 3500 skilled mechanics at work in the shops and a gang of 1800 German prisoners and civilians doing such general work as making roads, laying foundations for buildings, unloading freight cars, etc. The whole organization had grown so fast that outsiders had not had time to marvel at it. Paris had not heard of its existence. Other branches of the army knew in a vague sort of a way that a reconstruction park was being erected and assumed that it was still in the erection stage.

There has been a lot of quick work done by the American Army in France, but it is doubtful if there is anything to equal this job of erecting an automobile reconstruction park to employ 3500 men, and having those men working at their own trades within 4 months of breaking ground. And these M. T. C. mechanics did not

*EDITOR'S NOTE—*W. F Bradley has studied motor transport during the war in France, Belgium and Italy and has been associated with this department of war since 1914. He assisted in the purchase of many automobiles and trucks for the A. E. F. in the summer of 1917 and personally superintended the overland delivery of many Fiat vehicles for our army. He made a minute investigation of the Salvage Park described in this article.*



Main street at Motor Reconstruction Park. On right are offices and stockroom; on left are machine shops

A line of trucks to be salvaged by Motor Reconstruction Park

apply to the Engineers Corps for assistance, nor did they requisition for labor battalions. Being practically all skilled workers from the automobile factories in the United States, they estimated that they were capable of erecting buildings, laying foundations, and installing machinery as efficiently as any bricklayers or masons. And they did it. It was not until after they had enough buildings up to enable all of them to be employed at the jobs for which they were specially skilled that they were given prisoner and civilian help for the rougher work.

The scope of this reconstruction park is to receive all the wreckage from the front, and to repair or salvage it, according to its condition; also it has to act as main supply depot for the Motor Transport Corps of the A. E. F. It has to cover all vehicles, with the exception of foreign makes, which go to a special park; and in addition to motor equipment it has to take care of all such Quartermaster horse-drawn vehicles as field kitchens, wagons, etc.

The Wreckage of War

Up at the front, 120 miles away, they collected everything on wheels which they were unable to repair, loaded them on freight cars, and dumped them by the train load in the grounds of the reconstruction park. When the front was quiet there was a steady stream of vehicles which had broken down in service, or which had been damaged in accident. But after every big battle there came a mad torrent of almost indescribable wreckage.

Looking it over, the question which naturally arose was, "How is it possible for automobiles to get into such a condition?" If a gang of ruffians had been put in possession of several hundred automobiles and told to wreck them so that they would look as unlike automobiles as possible, it does not seem conceivable that they would have succeeded in getting anywhere near the wrecking perfection attained by war.

They were all war wrecks covered with a thick coating of yellow, French mud. With some the story could be traced, as for instance the Cadillac limousine which had been in the direct line of a bursting shrapnel shell, and which had been sent back with blood, bits of flesh, remnants of uniform and equipment intermingled with its torn upholstery and horsehair stuffing. A few weeks later that car went out practically new, and the men who are riding in it at this moment undoubtedly are unaware of the grim tragedy attached to it.

As there was no time to prepare the ground, a Holt tractor had to be used to haul damaged trucks inside the park

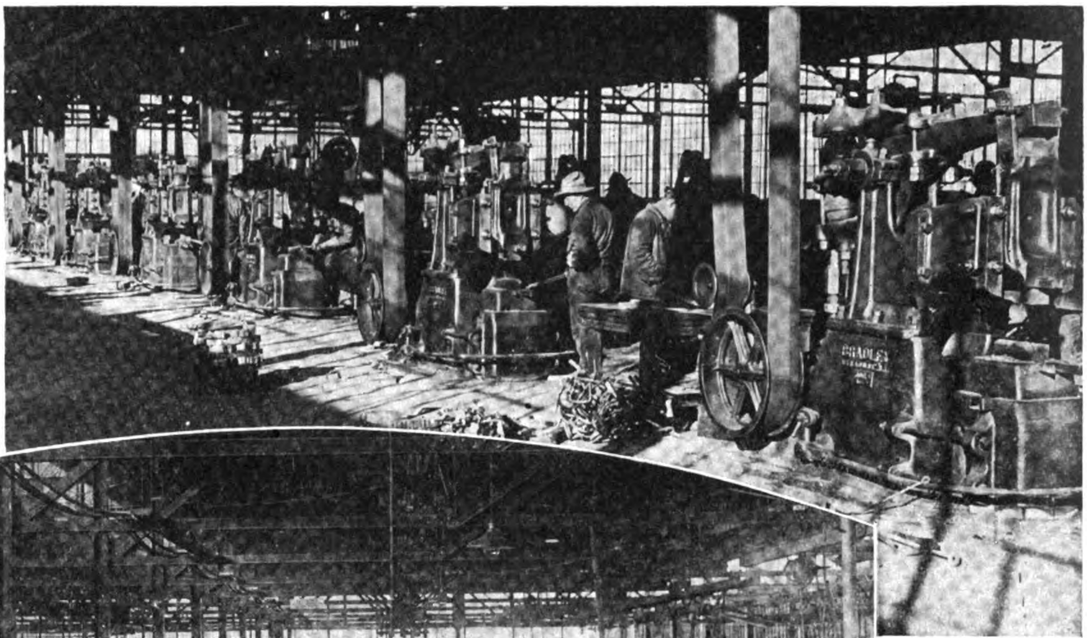
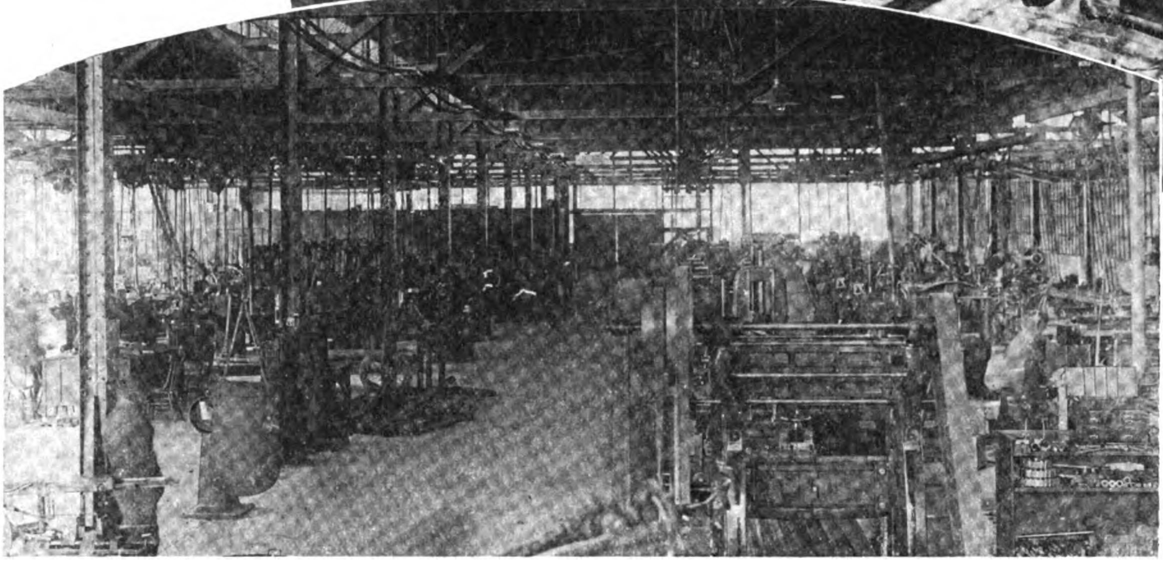
Left—Gas compressors at Motor Reconstruction Park. Right—Part of power plant. White steam engine being installed. Gasoline-electric groups developing 700 hp. are made use of



One line of the 14 Bradley hammers in Motor Reconstruction Park



One of the four machine shops

How a six-cylinder Mercedes aviation engine, complete with radiator, instruments and some of the fuselage, found its way into a wrecked American truck and was then dumped off into the mud of the reconstruction park, nobody ever will know. But the mechanics accepted it without asking any questions, stripped it, relined the bearings, repaired the pierced intake manifold, which had been the original cause of its capture, and soon had it in running condition.

It takes the better part of a day to completely travel over the whole of the motor reconstruction park, of which Colonel H. A. Hegeman is the commanding officer and of which Major J. A. Hickey is the master mechanic. The main office, right in the center of the camp, is an Austin type building 100 by 140 ft., with modern office furniture, a telephone on every desk, and the commanding officer accessibly placed at the head of the building, with the whole of the service under his direct supervision. This American method of placing the chief in the same buildings as his assistants, accessible to every visitor, is an unfailing surprise to the French, who have been taught that a leader's importance is measured by the number of doors separating him from his subordinates.

Of the 337 acres of ground given over to the reconstruction park, 207 had been covered between May 8 and Nov. 1, and the floor space of the shops comprised 485,300 sq. ft. Most of the buildings are of the Austin type, of steel construction, with a small amount of brick. Generally they are 100 by 260 ft. In addition to a number of others of different type, four of these Austin buildings had been erected and were in full operation early in November. The first one was a metal working shop, given over to the repairing of tanks, radiators, gasoline drums, etc. The following, and similar sized building, was a machine shop, fully equipped with modern machinery for all kinds of work. The third building in line was a machine shop with a thoroughly up-to-date tool room. The fourth was the forge, having among other equipment ten Bradley drop hammers and a modern spring making department, controlled by a specialist from Detroit, who produced from 40 to 60 sets of springs per day.

The main engine shop is of different structure, being a long building 639 by 96 ft., with seven bays, each 240 by 50 ft. This shop has 72 engine stands and 14 special Ford stands. It completely overhauls 90 to 108 engines per week. The wood-working department comprises two main buildings, each 100 by 260 ft., fitted with power-driven saws, planers, mortising machines, etc., and used specially for rebuilding horse-drawn vehicles. Adjoining are separate buildings for automobile upholstery, leather work, tops, hood covers. There are completely equipped shops for battery work, for electrical appliances, and for magnetos.

Most of the acetylene, oxygen and hydrogen required by the M. T. C. is produced at the reconstruction park and sent out from there. The plant, at the time of my visit, was filling 60 big acetylene bottles and 69 motorcycle acetylene bottles per day. In the hydrogen and oxygen department 80 of the former and 40 of the latter bottles were being filled, each bottle having a capacity of 200 ft. The compressors were under cover, but the gas lines were led out of doors, so that the actual filling was carried out in the open air. The filling of the motorcycle acetylene bottles was done under water.

Buying Uncertainty

RARELY has there been such a wary attitude on the part of purchasing agents in going ahead with their inventories for the coming year as there is at present. At this season of the year the material for summer production is generally well in hand, but this year the purchasing agents are not buying more than a month or two ahead, except in very particular instances where the market conditions appear particularly favorable. One of the main reasons for this is the inability of the purchasing agent to accurately gage whether or not there will be a further drop in steel prices. The slowness of the Government in making adjustments on contracts is another factor, and there is no doubt that the continued control of the railroads by the Government is also having an effect, as this has influenced to some extent the release of purchase orders for steel by the railroads.

The practice of "hand to mouth" buying is disturbing and expensive. The cost of handling small orders is almost as great as that of handling larger ones, with the resulting tendency to keep costs up. It is about time that stabilized conditions were reestablished in the industries, and if purchasing agents generally will gather a little more confidence in the situation and act on their beliefs that prices cannot come down materially for some months, it will at once relieve the situation.

Uncertain conditions are not confined to the automotive industry, but obtain in all industries, and the inter-locking relationships of different industries make the uncertainty in the purchasing field of a contagious nature. Once the field goes ahead on its knowledge that material prices are not apt to change radically during the next few weeks, it will have a marked stabilizing effect on business in general.

Since there are no signs at the present time that wages will be reduced, it is quite certain that all other matters are going to remain in about the same state, and reductions in the price of materials, of labor and of factory space are not to be looked for during the balance of this year. The important point is to have manufacturers realize this condition and that they should go ahead and buy for manufacture on a longer time schedule than is being done at present.

Tractor Demands

THE open winter permitting plowing with horses and thus getting away from the peak of early spring plowing, to a measure accounts for the slowing up of tractor demand on the farm, but this is not the complete explanation of the situation. The farmer is better able to purchase tractors today than at any time in his history, but he still holds back and may continue to hold back for 2 or 3 months more until he harvests the present crop.

Possibilities of lower prices are holding back many sales. The small reduction in steel prices is looked upon as but a starter, and the farmer considers himself peculiarly fortunate in being able to get by this spring without investing in a tractor and at the same time not have to reduce his crop acreage.

Too few people in the country realize that prices cannot drop to the pre-war level, but unfortunately the farmer is not one of these few. He looks too often for the price pendulum to swing back to the 1914 level, which it will never do. A little educational work by the tractor makers would accomplish a great deal in analyzing the price situation to the farmer. It would be a much more constructive and positive method of merchandizing than cutting prices.

The present offers a quite confused situation—open spring, high costs of materials, and increased production facilities with many concerns. The trouble will remain for a few months, perhaps until the present crop is harvested, after which it is difficult to see how there cannot but be a big tractor demand. The farmer may perhaps not in a generation be favored with such a set of conditions. It behoves the manufacturers not to do anything that will rock the boat.

Co-operative Plans Between Organization and Labor

CO-OPERATION is very largely psychological, whether it is between the employer and the employee or between persons occupying approximately the same business plane. You have two parties in co-operation, and if the co-operation is to be real then it must result from the united effort of both parties.

It cannot come if the plan is worked out by one of the parties and thrust on the other. That is not co-operation, but rather coercion. The plan must be one of mutual evolution.

In the labor problem many of the so-called co-operative plans have failed because they were evolved entirely by the employer. He worked out the entire plan. The workers were not consulted in it. The employer not only conceived the plan, but put it up to the workers as his plan. They had no voice in it. They were merely asked to accept it.

It did not get a favorable reception from the workers because it was thrust upon them more or less as a charity measure so far as any additional wages were concerned. As such it flavored too strongly of paternalism. It was not co-operation in the sense of two parties working to do a job better and for the improvement of the two parties on an equal basis.

It is not surprising that some workers view with suspicion such co-operative plans which have been cut and dried by the management and then thrust before the workers for speedy ratification by them. Too frequently the workers view the plan with suspicion.

Let the employer put himself in the place of the worker: Let the workers thrust into his hands a carefully worked-out plan of factory management and division of profits and then ask for the ratification of it by the management in a single day.

What management is there that would not want to refer such a document to a corps of lawyers and have it gone through from end to end to find the nigger in the fence?

After receiving such a document the employer might see that real, enduring co-operation must arise from the co-work of two parties in which each is a factor in evolving the plan. The plan must come from both sides. It must be the product of mutual conception and deliberation.

It is this psychological aspect of the worker that Charles P. Steinmetz lays special emphasis on in his address printed on another page in this issue. It is to the failure to recognize this factor that he attributes the failure of so many so-called industrial relationship movements.

The worker has been suspicious of what has come from the management because, as Dr. Steinmetz says, the trouble between capital and labor today is a historical one. It began more than a generation ago and being of such long standing cannot be corrected in a day, a week or a month.

Unfortunately, labor and capital in too many cases occupy hostile camps. Instead of working together for increased production and reduced prices with the greater profits that ensue, labor stands off in its camp and capital stands opposite in its camp.

With the higher average of educational training the employer should take a broader view of the situation than labor. If education is to be of value, this is one way in which it should exhibit itself. Breadth of view is a natural product of education.

To start the solution process and to untangle the present knot, labor must see capital take the initiative.

Capital has been the stronger and as such can the more afford to approach the subject on a real basis of co-operation. Capital must give the worker a free opportunity to discuss the plans. The worker cannot be expected at the start to have as complete a grasp of the situation as the management and will make errors. These will have to be handled carefully.

The organization will discover it has an educational work on hand that it is obligated to carry on. It will require greater investments for this work than many organizations have been accustomed to make, but the goal is deserving of the price, and we cannot afford to fall short in the attainment.

Overland Refuses to Increase Wages

Employees Threaten Walkout But Have Not Done So Yet—General Labor Unrest

DETROIT, April 17—The Willys-Overland Co. has refused the demands of its employees for increases in wages amounting to from 15 to 40 per cent, but though an immediate walkout has been threatened, this has not occurred. Vice-President C. A. Earl does not believe that the men will walk out, his belief being based on the fact that on Monday the Willys-Overland Co. will make the first distribution of profits under the profit-sharing plan which it recently adopted. This will give about $200,000 to employees who have been in the service of the company for more than 6 months.

The workers definitely demanded an increase of 15 cents per hour, the demand representing a total of 12,000 workers. They also demand that piecework be abolished and the working day be shortened to 8 hours, with 4 hours Saturday, and double time for overtime work.

Willys-Overland has not reduced the war wage scale. The demand for an increase would put wages from 15 to 40 per cent ahead of this scale and, if granted, would cost the company approximately $4,000,000 annually.

General Demand for 8-Hour Day

The discontent in labor circles is not confined to the Overland plants. In and around Detroit labor is in a state of unrest, with a general demand for an 8-hour day. The workers do not want their labors reduced to 8 hours a day, but want a 9- or 10-hour day with double time for the one or two hours overtime. At the Wadsworth Mfg. Co., which is a large top maker, the day force of 300 men has walked out, demanding a general increase in wages.

There is no longer any unemployment in Detroit, the pendulum having swung the other way. It is now difficult to get skilled labor, though unskilled labor is plentiful. Skilled men are averaging 65 cents per hour and unskilled men 45 cents.

Apparently there is a stable element among the older men, who have saved money and built homes, and this is having a good influence. The general impression is that the employers will win out.

Another matter which is causing some trouble is the competition among cities for labor. Cities around Detroit resent employers in Cincinnati, Cleveland and Detroit advertising in papers in those cities for help.

Sinram Heads Gear Makers for Third Term

CLEVELAND, April 16—F. W. Sinram, of the Van Dorn & Dutton Co. of this city, who has been president of the American Gear Manufacturers' Association since its formation at Lakewood, N. J., two years ago, was unanimously re-elected for a third term at the annual meeting of the association held here yesterday.

Fordson Plant Closed for Inventory

DETROIT, April 17—The Henry Ford & Son factory plant at Dearborn has closed down for the first time in 18 months and will remain closed for 2 weeks for a general inventory. The plant has been running three 8-hour shifts daily. On Saturday there was a clean-up and 914 tractors were turned out. The normal daily production has been running about 240 to 250 tractors. To date 53,075 tractors have been completed.

Want Government Tractor Tests

CHICAGO, April 11—Tractor manufacturers who are members of the Tractor and Thresher Department of the National Implement & Vehicle Association, at a special meeting to-day formally expressed to the Department of Agriculture at Washington a desire that it establish a bureau to conduct tractor tests to determine draw-bar and belt-power ratings of machines and to furnish a certifictae of the findings made by the bureau on each tractor tested. It is believed that certificates of power ratings, issued by a government bureau, would be of such standing nationally and internationally as to fully satisfy all interested persons.

Under this plan a variety of tests proposed by the several state legislatures would be done away with, and a much more satisfactory uniform national rating would be applied. This would eliminate the tremendous expense of the manufacturers in having their tractors tested by each of the states and would eliminate the variety of conditions to be met under the state control in all sections of the country. With the rapidly increasing volume of export trade, the tractor manufacturers feel that a federal certificate of horsepower ratings would be more recognized by all foreign countries.

A committee of the Tractor & Thresher Department was appointed to bring this matter before the proper officials at Washington in the hopes that this very desirable legislation may be procured.

Repair Agencies for Trucks Sold to A. E. F.

WASHINGTON, April 15—Thirteen American truck and car manufacturers have arranged to maintain agencies in Europe to supply parts and make repairs for all vehicles sold by the A. E. F.

S. A. E. Summer Meet June 23-27

Will Combine Business and Recreation Convention at a Great Lakes Hotel

NEW YORK, April 17—The summer meeting of the Society of Automotive Engineers will be held at Ottawa Beach, an exclusive summer resort on the east shore of Lake Michigan, 6 miles from Holland. The society has secured the exclusive use of the Ottawa Beach Hotel and cottages for June 23-24-25-26 and 27. Accommodation will approximate 1000 members and guests. The Standards meeting will be held Monday, June 23. In the evening the annual business meeting will take place and on Tuesday, Wednesday, Thursday and Friday professional sessions will occupy the program. Two half days will be given over to recreation and sports.

The rule which barred ladies from attending the sessions the last 2 years during the war has been waived and members will have an opportunity of taking their families and combining a vacation with the summer meeting.

The Meetings Committee, in deciding upon the nature of the meeting, took a mail vote of over 100 members to discover the kind of meeting they desired, and the vote was overwhelmingly in favor of a convention of professional sessions and recreation. The members are anxious to have an opportunity of fraternizing with one another and discussing many matters that cannot be discussed in a regular meeting. In view of this, approximately 30 per cent of the time will be given over to recreation and sports.

The program has not been definitely outlined as yet, but the general plan is to devote 50 per cent of the time to discussion and handle only a few important subjects. Thus the "Future Design of the Passenger Car" will be the subject for an entire session.

In a similar way the questions relating to production as concerned with cars, trucks, tractors, motorcycles, etc., will be the subject of an entire session. It is hoped to handle motor trucks, farm tractors and aviation in a similar way. There will be papers on motor boating, electric lighting systems, etc.

The Meetings Committee that has the meetings of this year in charge has been appointed by President Manly and consists of: Chairman, David Beecroft, W. A. Brush, C. F. Scott, B. G. Koether and Dent Parrett.

Automotive Industries

General Motors Sales $326,044,755

Financial Report Shows Large Increase in Profits, Assets and Capital

NEW YORK, April 12—Net profits of the General Motors Corp. for the year ended Dec. 31, 1918, increased $26,127,-754 over the balance for the previous year, and during that time net sales of all companies were 246,834 cars, valued at $326,044,755. During the year the company's assets increased $165,699,611. This increase in assets is made up to a considerable extent of increased holdings in real estate, amounting to approximately $46,000,000; $27,000,000 increased investment in Liberty bonds, about $44,-000,000 increased value of inventory, $7,000,000 due from the government on war contracts, an increased valuation of $24,000,000 on good-will, patents, etc., and about $16,000,000 increase in notes and accounts receivable.

After deducting reserves for federal taxes and other contingencies amounting to $28,000,000, the surplus for the year increased $24,900,545 and is now $36,-408,937. On Jan. 1, 1918, the working capital of the corporation was $64,554,-765, but by Dec. 31 this had increased to $149,902,028, the increase being $85,347,-263. The net manufacturing profits amounted to $35,504,576, after deducting $4,616,344 to cover depreciation of buildings, machinery and equipment. These profits are exclusive of profits which accrued to the several companies in 1918 prior to their acquisition by the corporation.

The combined profits of the corporation and subsidiary companies before deducting Federal taxes for the twelve months ended Dec. 31, 1918, and including the proportion of profits which accrued to the several companies in 1918 prior to their acquisition by General Motors, amounted to $45,541,726.

Included in the consolidated balance sheet are the assets and liabilities of the following divisions and subsidiary companies, in addition to various sales companies with nominal capitalization:

GENERAL MOTORS GROUP

Buick Motor Co. Division..............Flint
Cadillac Motor Car Co. Division......Detroit
Central Forge Co. Division...........Detroit
General Motors Truck Co. Division..Pontiac
Jackson-Church-Wilcox Co. Division.Saginaw
Northway Motor & Mfg. Co. Division..Detroit
Oakland Motor Car Co. Division.....Pontiac
Olds Motor Works Division.........Lansing
Samson Tractor Co. Division......Janesville
Scripps-Booth Corp. ....Detroit
Champion Ignition Co..................Flint
The McLaughlin Motor Car Co., Ltd..Oshawa
The McLaughlin Carriage Co., Ltd...Oshawa
General Motors Export Co.........New York
General Motors (Europe), Ltd........London
Janesville Machine Co.............Janesville

CHEVROLET GROUP

Chevrolet Motor Co. of Michigan ......Flint
Chevrolet Motor Co. of New York, Inc. Tarrytown
Chevrolet Motor Co. of Texas ...Fort Worth
Chevrolet Motor Co. of St. Louis..St. Louis
Chevrolet Motor Co. of Canada, Ltd..Oshawa
Chevrolet Motor Co. of Bay City...Bay City
St. Louis Mfg. Corp................St. Louis
*Toledo-Chevrolet Co. ....Toledo

UNITED MOTORS GROUP

Dayton Engineering Laboratories Co..Dayton
Hyatt Roller Bearings Division......Newark
Jaxon Steel Products Division.......Jackson
Remy Electric Division.............Anderson
Harrison Radiator Corp.............Lockport
New Departure Mfg. Co..............Bristol
Lancaster Steel Products Co......Lancaster

Following are excerpts from the report of the General Motors Corp.:

The net sales of General Motors Corp. and subsidiary companies for the twelve months ended Dec. 31, 1918 (not including the sales of the companies purchased during the year prior to their acquisition), amounted to $269,796,829.78. The net sales of all companies for the twelve months ended Dec. 31, 1918, amounted to $326,044,755.95. The number of cars, trucks and tractors sold during the year was 246,834.

The payrolls for the year 1918 aggregated $52,500,000. The number of employees in the service of the corporation and its subsidiary companies on Dec. 31, 1918, was 49,118.

Concerning the work done by the corporation on war products, a word at this time may not be out of place. Of the twenty-three operating units, eighteen were engaged on government contracts. The gross value of the products actually completed was approximately $35,000,000. At the time the armistice was signed the orders and contracts in hand exceeded $50,000,000.

The United States had been at war hardly a month when the Truck Division received a large order for its Model 16 chassis to be used for ambulance mounts. During the Mexican trouble this chassis, in actual service, had proven to be especially well adapted to ambulance work and was adopted by the Medical Corps for all motorized units. In the summer of 1918, after having spent months on the design of a new chassis for universal military service, the Army finally acknowledged the sterling worth of the G.M.C. Model 16 chassis by making it the standard ¾-ton chassis for all arms. General Motors furnished over 5000 of these vehicles.

The Quartermaster's Corps, supplying the majority of the vehicles used by all branches of the service, early adopted the Cadillac as the standard officers' car. A total of 2350 Cadillac cars practically standard in all respects were supplied.

The Cadillac eight-cylinder engine, with a few slight changes, was adopted by the Ordnance Department as the power plant for the 2½-ton artillery tractor. A total of 1157 engines were supplied for this purpose.

In the production of Liberty motors for aircraft work, the Buick and Cadillac divisions made an exceptional record. Regardless of the delayed start, due to the fact that the General Motors Corp. had been

To Sell 1000 Liberty Engines

WASHINGTON, April 17—One thousand Liberty engines have been placed on sale by the War Department. They are 12-cylinder, V-type, 5 x 7, 400 hp., at 1700 r.p.m., and are equipped with a Delco generator, battery-type ignition, and two complete distributing units working independently with specially designed Zenith duplex carbureter. These engines are all new and are a surplus above the requirements of the Air Service. Bids should be made to the Sales and Salvage Section, Army Air Service, Washington.

SKF and Hess-Bright Brought Together

With Atlas Ball, They Form SKF Industries—Establish Research Laboratory

NEW YORK, April 17—The SKF Administrative Co., which was formed in May, 1917, to consolidate the interests of the SKF Ball Bearing Co. and the Hess-Bright Mfg. Co., has been merged, with the Atlas Steel Ball Co. into a new company to be known as SKF Industries, Inc. The Atlas company has for some time been controlled by the SKF company.

The immediate purpose of the merger, which brings together the sales and executive departments of the three companies, is to facilitate the carrying on of important research work. For this purpose ground is being broken adjacent to the Hess-Bright plant in Philadelphia.

The merger will not affect the financial status of any of the companies and is largely to simplify merchandising problems. Heretofore, Hess-Bright and SKF bearings have been sold separately and in competition. Hereafter, they will be sold by the same sales organization, with the assistance of the research and engineering laboratory, and not in competition. Both names will be perpetuated, Hess-Bright for the company's deep-groove type of bearing, and SKF for its double-row self-aligning type. The establishment of the laboratory permits the company to give scientific advice on anti-friction matters, entirely divorced from the sale of any specific type of bearings.

B. G. Prytz, who has been president of all three companies, is president of the new company. Associated with him are: Vice-president, W. L. Batt, formerly vice-president of the Hess-Bright company; Comptroller J. P. Walsh; Sales Manager S. B. Taylor, formerly vice-president of the SKF company.

The company will consolidate its sales and executive offices at 165 Broadway, New York. The SKF, Hess-Bright and Atlas plants, the former in Hartford, and the latter two in Philadelphia, will be maintained without change.

—

Holt-Best Patent Litigation Settled

SAN LEANDRO, CAL., April 11.—Litigation between the Holt Mfg. Co. and the C. L. Best Gas Traction Co. over certain patents has been adjusted. The Holt company has acquired the Lombard patents, Nos. 674,737 and 854,364, from the Best company and has licensed that company to manufacture under the Holt patents. The number of the patent in the suit instituted by Holt is 874,008.

Militor-Knox Merged as Militor Corp.

Will Continue Militor Motorcycles and Knox Engines and Add Passenger Car

NEW YORK, April 12—The Knox Motors Co., Springfield, Mass., and the Militor Corp. have been merged and will do business as the Militor Motors Co., with a capital of $2,500,000. The company plans to increase the production of Militor motorcycles and will also add a light passenger car. It is planned to continue production of Knox engines.

The original Militor Corp. was organized for the production of war vehicles for the Government, and received contracts for a considerable number of four-wheel-drive trucks, though these contracts were canceled before the company could get into actual production on them. The Militor motorcycle is a four-cylinder, shaft-driven vehicle which differs from other motorcycles in that it is of automobile construction to a very great extent.

N. R. Sinclair, president of the Militor Corp., will be president of the new company. Associated with him are George W. Dunham, vice-president of the Militor Corp. and formerly president of the S. A. E.; second vice-president, R. L. Notman, secretary of the Militor Corp. and formerly vice-president of the McKinnon Dash Co.; treasurer, E. O. Sutton, formerly treasurer of the Knox Motors Co. Production activities will be centered in the Springfield plant, which has more than 230,000 sq. ft. of floor space and a complete equipment of machinery. General executive and sales offices are at 111 Broadway, New York.

Fokker Airplanes to Be Made in Holland

WASHINGTON, April 12—A factory is being erected in Holland for the manufacture of Fokker airplanes, according to information received here by the War Department. Two American army officers, Col. Earl McFarland and Major Robert Marsh, Jr., have been assigned to visit the factory and study the Fokker plane, afterward reporting to the American military attaché at The Hague.

U. S. Chamber of Commerce Convention at St. Louis

WASHINGTON, April 12—The meeting of the Chamber of Commerce of the United States at St. Louis, April 28-May 1, will include in its program discussion on the disposition and operation of the country's railroads and merchant marine, revision of anti-trust legislation, foreign relations and foreign trade, agriculture, industrial production, domestic distribution, waterways and highways, industrial relations and finance. The Advisory Council of American Industries, which comprises 400 war service committees, has been asked to attend the meeting.

Speakers already designated include Carter Glass, Secretary of the Treasury; William C. Redfield, Secretary of Commerce; Edward N. Hurley, chairman of the Shipping Board; Walker D. Hines, Director of Railroad Transportation; Senator Albert B. Cummins; George Ed Smith, President of the Manufacturers' Export Association, and Maurice Casenave, former French Minister to Brazil, now Director-General of French Services in this country, who will speak as the special representative of France.

French Accessory Competition

PARIS, March 26—On June 9 the Touring Club of France will hold a competition for the equipment of automobiles for extensive touring and camping. This competition is a part of the program drawn up by the club in celebration of its twenty-fifth anniversary.

It is felt that very few automobiles are so designed that accessories, such as tires, rims, tools, batteries, etc., can be carried conveniently. The object of the competition is not only to find the best ways of lodging these essential accessories, but also to reveal the best methods of carrying baggage and touring equipment. Light two-wheel trailers suitable for placing behind a passenger-carrying automobile will be admitted at this competition.

Major Halford in America in Interest of English Patents

NEW YORK, April 12—Major F. B. Halford, representing Engine Patents, Ltd., of England, which developed the Ricardo cross-head piston type engine used in the British tanks, and also the slipper design of piston, arrived in New York recently in the interest of American patents on these products, and also the possible development of them in America.

Major Halford was one of the three to develop the B.H.P. aviation engine which was used so much in British bombing planes, and of which perhaps over 6000 have been built. The B.H.P. was a 6-cylinder design and in 1916 was fitted in the first DH-4 bombing plane. With cylinders 145 x 190 it furnished approximately 1 hp. for every 2¼ lb. in weight. The object of the development of the B.H.P., which took its name from the three men who worked on its development, namely, Sir William Beardmore, Major Halford and T. C. Pullinger of Arrol-Johnson, was to give maximum reliability without excess weight. It was a direct-drive engine, and with its use the speed of the bombing planes was increased from 92 to 116 m.p.h.

Closing of Cleveland Plants Throws 1200 Out of Work

CLEVELAND, April 11—The entire works of the Theodore Kundtz Co., comprising five plants, were closed to-day, throwing more than 1200 men and women out of work. Officials say that the step was taken because of agitation among the workers for a wage advance of 10 cents an hour and a 6-hr. day.

$152,000,000 Voted for French Roads

$112,000,000 for Devastated Area —65,000 Miles to Be Entirely Rebuilt

PARIS, March 25—The sum of $152,000,000 has been voted by the French Government for the repair and upkeep of roads. Of this amount $112,000,000 will be devoted to the repair of roads in the devastated regions of France. Approximately $40,000,000 are to be spent on the repair of roads which have indirectly suffered owing to the war. These include roads which, owing to military activities, have had to carry an amount of traffic for which they were never designed.

Careful examination of the roads situation in France shows that 65,000 miles of main roads in the war area must be entirely rebuilt. In addition to this several hundred bridges, which at present are of a temporary nature, must be reconstructed. It is estimated that to put these war-stricken roads into proper condition 10,400,000 tons of material will be required. The estimated cost of this work is $64,000,000. This is in addition to the $48,000,000 which have already been spent by the military authorities during the war for the maintenance of roads in the war area.

For the past 4 years all the roads in the war zone of France have been under the direct control of the army authorities. At the end of April this control will be taken away from the army and vested in the Ministry of Public Works, which will occupy itself not only with the main or national highways, but also with the local or departmental roads. In the past the State only maintained national roads, leaving the upkeep of the secondary roads to the department or local authorities. In view of the enormous task facing it, this divided control has been abolished. All the gravel pits and stone quarries at present worked by the military authorities will be taken over by the Ministry of Public Works. Also all road work which is now handled by the American and British armies will be transferred to the French civilian authorities. Many of the contracts for this scheme have already been placed, and it is believed that active work on the repair of roads will begin by the end of April.

Repair Outside War Zone

The second part of the program, which deals with the repair and improvement of roads outside the war zone, is almost as big as the first. In asking for and obtaining a credit of $40,000,000 the French authorities realize that a tremendous effort must be made to make the roads equal to their condition of 10 years ago. A technical committee has been appointed to determine the kind of material necessary for each type of road. It is probable also that there will be a reclassification of roads.

Since the development of the automo-

bile many roads which were classified as fourth or fifth grade have become of primary importance. These roads should have spent on them an amount of money commensurate with the traffic they have to carry. Under this scheme it is estimated that it will be necessary to furnish immediately 5,000,000 sq. yd. of broken stone and to repair more than 1,000,000 sq. yd. of granite-paved road.

Pershing Highway Planned

WASHINGTON, April 11—The Department of Labor plans to construct a highway, to be known as the Pershing Highway, across the continent from New York to San Francisco, touching various places connected with the life of the commander of the American Expeditionary Forces. A temporary association has been formed for this purpose, and it is believed all the States will co-operate. A preliminary meeting was held in Lincoln, Neb.

The approval of Congress will be necessary, and appropriations made by Congress. Nearly 800 road projects have been approved in various States, and $21,000,000 as now available for State roads, according to the Federal Road Aid Act, by which the Government allows the individual States as large an amount as the States themselves appropriate for road construction.

Nebraska has taken the lead in the Pershing idea and also has 13 road projects of 388 miles approved at a cost of $809,401.43, of which $320,206.66 will be from the Federal funds. New York State has received Federal approval for 13 projects of 61 miles and California has had approved 6 projects covering 96 miles at a cost of $1,290,613.84.

Road-Building Freights Cut

WASHINGTON, April 12—Reduced rates on road building material for Federal, State, county or municipal work were ordered yesterday by the Railroad Administration. All railroads were authorized to cut, without filing tariffs, 10 cents a ton from regular rates exceeding 40 cents a ton on all shipments of broken, crushed or ground stone, sand and gravel, slag, shells, chatts and cherts, where the benefit of the reduction would accrue to the Federal, State or local governments.

Director-General Hines took this action after conference with the Departments of Agriculture, Commerce and Labor.

Gasoline Stocks Are Well Maintained

January Figures Disclose Satisfactory Position—Production Has Increased During Month

PRODUCTION

	January, 1919	December, 1918
Crude oil (bbl.)	26,967,332	26,958,157
Gasoline (gal.)	303,710,556	291,744,465

	Stocks on Hand Jan. 31, 1919	Stocks on Hand Dec. 31, 1918
Crude oil (bbl.)	15,380,185	15,749,771
Oils purchased to be re-run (bbl.)	1,088,264	1,300,018
Gasoline (gal.)	383,212,692	297,326,983
Kerosene (gal.)	332,393,181	380,117,829
Gas and fuel (gal.)	646,411,414	359,001,357
Lubricating (gal.)	158,370,431	138,853,574
Wax (lb.)	189,064,329	199,657,542
Coke (ton)	28,732	22,605
Asphaltum (ton)	93,027	76,858
Miscellaneous (gal.)	483,942,833	477,783,740

WASHINGTON, April 14—In comparison with the past few months, the figures relating to petroleum products for the month of January, 1919, are very satisfactory.

It is true that production of crude oil has remained practically stationary as compared with the total for December, 1918, and gasoline production has increased by less than 12,000,000 gal. Nevertheless we are now getting the benefit of decreased consumption and, accordingly, the position in regards to stocks held on Jan. 31 last is distinctly good.

It is reasonable to suppose that gasoline consumption should be at its lowest point around January, and no doubt it is mainly for this reason that our stock has increased by about 85,000,000 gal. Stock of fuel oil has increased by no less than 287,410,057 gal., a circumstance which augurs well for the maintenance of our new oil-burning merchant marine. Our stock of lubricating oil is also satisfactory, but stocks of crude and kerosene show slight decreases.

Almost all through the year 1918 consumption of crude petroleum and, inferentially, its derivatives has been in excess of production. In June the lines of production and consumption crossed for about a week, but later on the position altered and it was not until almost the end of December before production was again in excess of consumption. In January, 1919, both consumption and production dropped, but as the former decreased more rapidly our position improved.

Gasoline Shortage Affects South African Trade

WASHINGTON, April 12—Shortage of gasoline in British South Africa has affected the use of motor cars and trucks, according to a report from the American consul. Sales of gasoline were suspended by the Government in order to insure adequate supplies for military use. The position is not so serious now, and gasoline is again being sold for commercial requirements.

Parliament has legislated that no excise duty should be levied on Union spirits or on ether manufactured from spirits, if they are used for internal-combustion engine fuel, in order to stimulate and encourage the establishment of a motor fuel industry. As a result a factory has been erected near Durban costing $400,000 and with a full capacity for 3000 gal. daily. This fuel is being placed on the market at a price just below that of gasoline. No statement can be made yet as to its success as a substitute fuel. Warnings have been issued against its used in carbureters with cork floats, as it apparently contains some denaturing chemical which quickly destroys the shellac coating.

Carload Shipments Increase 5000 in March

NEW YORK, April 15—Shipments of automobiles increased nearly 5000 carloads in March, 1918, over the same month last year. In March, 1918, the shipments totaled 16,728, as compared with 21,500 in March, 1919, according to figures presented before the monthly meeting of the directors of the National Automobile Chamber of Commerce.

In the last month the condition of the factories in so far as their ability to get automobile freight cars is concerned has been materially bettered. This has been brought about through the efforts of the N. A. C. C. in having a representative of the railroads permanently located in Detroit with authority to check up and route freight cars.

DALLAS, April 15—The Spencer-Carroll Co. has moved from Waco, Tex., and will now operate its wholesale business in automotive equipment from that center.

Output of Refineries of the United States by Months

1918	Crude (bbl.)	Other Oils (bbl.)	Gasoline (gallons)	Kerosene (gallons)	Gas and Fuel (gallons)	Lubricating (gallons)	Wax (pounds)	Coke (tons)	Asphaltum (tons)	Miscellaneous (gallons)	Losses (bbl.)

Purchasing Pitfalls Pointed Out

Detroit Purchasing Agents Hear of Wide-Open Traps for the Unwary Buyer

DETROIT, April 14.—How to avoid legal pitfalls in buying was pointed out by Edward G. Wasey, a prominent attorney, at the April meeting and dinner of the Detroit Branch of The National Association of Purchasing Agents, held on April 9. Mr. Wasey pointed out a number of the wide-open traps which catch the unwary buyer unless he is posted on the laws which regard his occupation. His speech followed the banquet and was heard by about 100 prominent purchasing agents of Detroit. A digest of his remarks follows:

"In buying goods where the purchasing price is over $50, there must be a written contract in order to make the sale valid. If, however, special manufacturing operations have to be gone into to produce the goods, or if a part of the order has been delivered, a contract has been consummated. As a rule, however, goods purchased to the extent of over $50 must be purchased through a written contract.

"It is necessary that the man with whom the contract is made have the power to make the contract. This is something which must be watched carefully, as in the employee's contract with his company he may be limited in his powers, and the purchasing agent should not close the purchase, nor should the salesman, on the other hand, conclude a contract, unless he is reasonably sure that the person with whom the contract is being closed is empowered to make the purchase."

Another matter similar to this which must be watched is that a concern is doing business along the lines for which it is incorporated. That is, a corporation cannot be held responsible for debts incurred in doing business in a field for which it is not incorporated. For example, if a concern is incorporated to manufacture a certain article, and for some reason takes a part of its capital and invests it in a farm and starts paying on this farm and suddenly ceases payment to the land company, that land company would have no redress against the corporation, since that is a business beyond the powers of the corporation to conduct.

This defense, known technically to lawyers as *ultra vires* (meaning beyond the powers), is quite common and must be guarded against by the seller in making his contract. That is, he should know that the concern with which he is contracting is undertaking to do something that is directly in its line of business. Of course, the individual officers of the company are liable for the bill incurred in the case of an *ultra-vires* defense.

Another very important requirement is the use of printed forms of contract wherever possible. With such it is highly improbable that anything will be omitted from the contract. Mr. Wasey points out a very typical example of this. A lease was drawn up stating that the tenant was to return the property to the landlord in as good condition as he received it, taking into consideration normal wear and tear, and not including damage by the elements such as fire or flood. By an error the last phrase was left out.

The property was damaged by fire and the building burned to the ground, whereupon the tenant wrote the landlord asking him when he was going to rebuild the property. The tenant was very much surprised to receive a reply from the landlord stating that it was up to him to rebuild the property. A study of the lease showed that this important phrase had been left out and the tenant was forced to rebuild.

Another thing that both the purchasing agent and the seller must watch is that there is an agreement between the parties buying and selling. Sometimes, where a case is brought into dispute, one of the disputing parties will bring a mass of correspondence to the attorney's office, and somewhere in that correspondence is supposed to be evidence that the parties have agreed upon the purchase and sale, or on the specifications or other matters necessary in consummating the deal. Very often a careful search through the entire correspondence fails to reveal any such agreement. It is very necessary therefore, that the purchasing agent so arrange his correspondence on the matter of the sale or purchase as to bring out the fact that there is a definite agreement.

Another failure in the conducting of business along purchasing lines is that of the concern which fails to describe plainly the goods that are to be bought or sold. It is also highly advisable to put in the contract the exact purpose for which the goods are suitable. This then binds the seller to deliver materials or products which are satisfcatory for the purpose intended. Some of the purchasing agents go further than this, and are able to "get away with it" in most instances. They incorporate a phrase stating that the goods must be to the satisfaction of the buyer.

Mr. Wasey dwelt at some length on the bad results of buying too cheaply. If the price is made too low and the seller is not able to make a reasonable profit, the quality of the goods is lessened, or in some way the lack of profit is made up. A concern which forces another concern to operate at a loss to fill an order is not going to get the same sort of treatment as one that allows a reasonable profit, and eventually this curtailment of price will some back in some detrimental way to the purchaser.

The practice of canceling parts of orders increases the risk of the seller and naturally, since he is taking a higher risk, he will ask higher prices. In the case of cancellation, the buyer is also liable for anticipated profits and in some cases for a certain portion of the cost of material if it has been bought specially. The only way of getting around this situation correctly is to make an option form of contract. Wherever the buyer forces the seller to take a risk he must be willing to pay for it.

It is always advisable, if possible, to pay bills quickly. There are certain concerns which have a habit of sending out vouchers on the day the invoice is received or, at most, the day following. This practice is highly beneficial to the seller, as it is a factor in allowing him to turn over his capital more quickly.

Improvements in New DeDion

NEW YORK, April 17—The post-war program of DeDion Bouton has been slightly uncovered, and details of one of the new models which will be on sale in America by the end of June have reached this city. It about follows the previous DeDion design, using a "V" type 8-cylinder engine which is improved in many respects. Cylinder dimensions are 70x120 mm., wheelbase 134⅝ in. and tires 34x4½ in. with standard tread.

Several unusual features are the mounting of the four-speed gearset as a unit with the engine, and the adoption of a conventional rear axle, consisting of a stamped housing with floating drive shafts, in place of the former double type, consisting of a fixed axle with a separate driving system and the differential mounted on the frame and transmitting by two universal shafts to the wheels.

The car is fitted with a single-unit motor-generator for starting and lighting, driven by a silent chain. The springs are very flat semi-elliptical types. Thermo-syphon cooling is retained.

Kalamazoo Spring President Dies

DETROIT, April 17—Charles H. Eaton, president of the Kalamazoo Spring & Axle Co., died yesterday after a brief illness.

Government Vehicles Not For Sale

Federal Requirements Likely to Account For All War Trucks and Cars — Remainder to Makers

WASHINGTON, April 15—Reports, current during this past week, that many thousands of trucks and passenger cars would be thrown on the market in the next few days are untrue. The rumors are the result of action taken by the War Department to learn what possible surplus of trucks and passenger cars can be expected as a result of the reorganization of the army.

Following the inquiry by Acting Secretary of War Benedict Crowell, the Motor Transport Corps notified him that after detailing trucks and passenger cars to the various divisions of the army in accordance with the reorganization plans there will probably be about 30,000 motor trucks and 5000 passenger cars surplus, most of the passenger cars being Fords, while the trucks are divided up among all the different makes which were ordered during the war, some of them new and the balance used.

This surplus, however, is not an indication of a sale to the public. As soon as these amounts are definitely ascertained the War Department will ask the various government bureaus for requisitions for trucks and cars to meet their needs.

The plan is to first provide all government departments with their requirements and then if there is a surplus to allow the manufacturers to rebuy their cars and trucks at reasonable prices. Third, if after these two methods are used a surplus still remains, it will be disposed of by auction sale to the public. It is not expected, however, that there will be any vehicle left for public purchase, and it is very doubtful if there will be any for resale to the manufacturers.

The Post Office Department, the Department of Agriculture, the Department of Commerce, the U. S. Health Service and, in fact, all of the government agencies, are expected to make demands for a large number of the vehicles, probably for more than the War Department can spare. The Post Office originally requisitioned 16,000 motor trucks; 3000 of these have been delivered.

Of the remaining 13,000 the Post Office Department is now able to take only 4000 whenever the War Department can provide them due to the fact that the Post Office appropriation bill failed to pass in Congress in the recent filibuster. The remaining 9000 trucks will be asked for by the Post Office Department if the bill passes in the next session of Congress.

The Department of Agriculture has already signified a need for 1000 passenger cars, 4500 trucks and several hundred trailers, and anticipates that it will use considerable more than this as soon as it definitely formulates its road building program. The plan is to use these cars and trucks for road construction.

The U. S. Health Service has already taken 1000 ambulances, and will take all that the army can spare, which may possibly mean that ambulance bodies will be fitted to some of the truck chasses to meet the needs of the U. S. Health Service.

Likewise, the Departments of the Interior, Commerce, Labor, etc., are expected to ask for considerable numbers of vehicles, all of which can be turned over to the different government agencies under the Act of Congress which authorizes the Secretary of War to meet any such requisitions. Consequently it appears at this time that there will be very few vehicles, if any, remaining to be offered for resale to the manufacturers.

General Motors Sales $326,044,755

(*Continued from page* 867)

selected to build a special type rotary engine which was afterward abandoned, Liberty motors were being delivered within five months from the time the contract was taken. The high standard of excellence of the product of these divisions has everywhere been recognized. At the time the armistice was signed there were orders for over 10,000 Liberty aircraft engines on the books and 2528 Liberty engines were actually completed and delivered.

The Jackson-Church-Wilcox Division, operating an entire plant on trench mortar shells, reached a production of 20,000 per day. This division holds the record as the largest producer of these shells in America. Substantially every claim against the government has been satisfactorily adjusted.

The development of the tractor business is continuing most satisfactorily, and production of Samson tractors in quantities is expected to be reached shortly.

During the year the corporation acquired the following interests:

All the assets of Chevrolet Motor Co., a Delaware corporation (except 450,000 shares of General Motors Corp. common stock), as of May 2, 1918, paying therefor $28,268,400 par value of common stock.

All of the common capital stock ($1,000,000 par value) of the Janesville Machine Co., Janesville, Wis., on July 1, 1918, paying therefor $1,000,000 in cash.

A controlling interest on July 1, 1918, in the no par value common stock of the Scripps-Booth Corp., paying therefor through an exchange of securities on the basis of one share of General Motors common stock for six shares of no-par value Scripps-Booth stock.

All of the capital stock of Chevrolet Motor Co. of Canada, Ltd., the McLaughlin Carriage Co., Ltd., and the balance of the capital stock of the McLaughlin Motor Car Co., Ltd., not already owned by the corporation, as of Nov. 1, 1918, paying therefor $4,900,000 par value common stock and $550,000 in cash.

All the assets of United Motors Corp., subject to liabilities, as of Dec. 31, 1918, paying therefor $29,869,200 par value debenture stock, $9,956,400 par value common stock, and 106,000 shares of United Motors stock owned by General Motors Corp., plus an amount in cash equal to the dividends on the debenture and common stock subsequent to Oct. 1, 1918.

All the preferred and common stock of Lancaster Steel Products Co. and $1,566,000 par value of General Motors debenture stock as of Dec. 31, 1918, paying therefor $1,617,500 par value common stock and $500,000 par value debenture stock.

All of the ($387,100 par value) Harrison Radiator Corp. preferred stock as of Dec. 31, 1918, paying therefor $387,100 par value debenture stock and $38,710 in cash.

There was authorized an issue of $24,000,000 par value of common capital stock, which was sold without expense to the corporation, for $28,800,000 subject to the right of the common stockholders to subcribe therefor.

The corporation has adopted a bonus plan under which stock of the corporation is distributed each year as a reward to its employees, including employees of subsidiary companies, who have contributed to its success in a special degree, by their inventions, ability, industry, loyalty or exceptional service. It is hoped thereby not only to compensate services rendered, but also to encourage further efforts by making its employees partners in the corporation's prosperity. Under the bonus plan, the amount which may be distributed each year is determined by taking 10 per cent of the net earnings of the corporation after deducting therefrom an amount equal to 6 per cent on the capital invested. The bonus plan is in no sense a "profit sharing plan" in the meaning of that term as generally used. There was awarded for the year 1918, under this plan, a total of 24,334 shares of the common capital stock of the corporation, at a cost to the corporation of approximately $2,798,410.

The outlook for the coming year is most promising. Since the signing of the armistice and the subsequent liquidation of the war contracts, which your corporation was engaged in, the plants and facilities have been reconverted in an incredibly short time to their regular lines of activity, and as a result the manufacturing operations are considerably advanced, as is evidenced by the showing for the first quarter of 1919; the number of cars, trucks, and tractors sold to March 31, 1919, inclusive, being 82,456; the net profits before deducting Federal taxes are estimated at upward of $20,000,000.

Condensed Comparative Consolidated Balance Sheet of General Motors Corp. and Subsidiary Companies as of Dec. 31, 1918 and 1917

ASSETS

	Dec. 31, 1918	Dec. 31, 1917
Permanent Investment:		
Real estate, plants and equipment..	$86,818,414.51	$40,086,374.34
Less: reserve for depreciation.....	10,061,983.38	1,428,539.28

Surplus	$36,408,937.43	$11,508,392.57
Total	$299,489,335.73	$133,789,724.47

Income Account for Twelve Months Ended Dec. 31, 1918

Net profits after deducting all expenses of manufacture (including maintenance) selling and administration, as well as ordinary taxes, insurance and depreciation		$35,504,576.41
Less: Provision for Federal taxes and extraordinary expenditures		20,113,548.19
		$15,391,028.22
General Motors Corporation proportion thereof......		$14,825,530.19
Preferred dividends for 12 months at rate of 6%	$1,180,901.00	
Debenture dividends for 5 months at rate of 6%.........................	739,566.00	1,920,467.00
Undivided profits for 12 months ended Dec. 31, 1918.		$12,905,063.19

Profit and Loss Account

Profit and loss surplus at the beginning of the year..		$11,508,392.57
Add undivided profits per Income Account above....		12,905,063.19
Additions through acquisition of properties:		
Chevrolet Motor Company (of Delaware)	$8,065,083.10	
United Motors Corporation	9,714,607.59	
Other companies	653,100.98	
Profit from sale of new common stock..	4,800,000.00	23,232,791.67
		$47,646,247.43
Less: Cash dividends paid on common stock:		
February 1, 1918—3%..................	$2,292,150.00	
May 1, 1918—3%..................	2,292,567.00	
August 1, 1918—3%..................	3,205,704.00	
November 1, 1918—3%.................	3,446,889.00	11,237,310.00
Profit and loss surplus December 31, 1918.........		$36,408,937.43

NOTE—The various tangible and intangible assets acquired by the corporation during the year were valued and written on the corporation's books at the same aggregate amount as they had been carried on the books of the corporations so purchased. As these amounts are in excess of the par value of the securities of the General Motors Corporation issued in payment for such assets, the difference results in an addition to the surplus account of the corporation, as shown above.

The properties of the Chevrolet Motor Company of Canada, Ltd., The McLaughlin Carriage Company, Ltd., and The McLaughlin Motor Car Company, Ltd., which were acquired during the year, were appraised and the book values adjusted to agree therewith.

Will United States Hold Trade in the Argentine?

WASHINGTON, April 11—Asking the question, "Will the United States hold its present trade in Argentina?" Commercial Attaché R. S. Barrett at Buenos Aires states that while this country will lose business which will be diverted to Europe, on the other hand imports to Argentina of automobiles, motor trucks, parts and accessories should increase. He points to the fact that the war decreased imports on these commodities and that the great demand now will probably be filled by the United States.

His report states that American manufacturers are beginning to study, know and meet the requirements of the Argentine buyer, and with the establishment of two branches of important national banks of the United States in Argentina, together with the general adoption of trade acceptances, has made the financing of shipments to Argentina easier, and allows the American manufacturer to grant the credit necessary to compete with other countries.

He also states that American concerns are establishing branch houses in Argentina which sell automobiles and parts directly, and that this is encouraging trade. Furthermore, large Argentine concerns heretofore were controlled by large European capital, but are now buying in the United States, locating buyers in this country, and will probably continue their trade.

The United States, says the report, should be placed on a parity with European nations in the matter of shipping and freight rates, must train young men for foreign service, must adopt some plan to protect the Argentine buyer from unscrupulous and unreliable merchants, and should invest American capital more freely in South American securities of proven worth.

—

French Tractor Trials

PARIS, March 25—Agricultural tractor trials will be held in Lorraine about the end of May, and also in Alsace, near Strasbourg, at the end of September.

The Lorraine competition is scheduled for the neighborhood of Metz, where the earth is of a heavy nature. The Strasbourg trials will take place in light Alsatian soil.

These competitions are open to allied and neutral nations.

—

Kansas City Tractor Club Annual Dinner

KANSAS CITY, April 14—The Kansas City Tractor Club, with a membership of 29, gave $112,000 for the tractor show here this year, it was stated in the report of Guy H. Hall, secretary of the club, read at the annual dinner at the Hotel Muehlebach. The club is composed of managers of factory branches and distributers of tractors and tractor-drawn tools. The fifth annual Kansas City tractor show was planned for February, 1920, and Mr. Hall was elected secretary of the club and manager of the show for another year. Other officers elected were: President, R. F. Crawford; vice-president, M. R. Vorhees, and J. A. Keating, R. W. Johnston, Harry Kaufmann, G. T. O'Maley and L. T. Yount, directors.

—

Wichita Demonstration Date Pushed Forward

CHICAGO, April 12—It is likely that the Wichita tractor demonstration, which was scheduled for the week of July 21, will be held instead during the week of July 14. The advance in date is probably because of land conditions. The demonstration is being staged by the National Implement and Vehicle Association, of which E. W. McCullough is secretary and general manager.

—

Tractors Needed in France

WASHINGTON, April 12—Farm tractors are urgently needed in France, according to a report received by the United States Department of Labor, and especially those of the heavier types capable of plowing land that has lain fallow for the last four years and which is practically buried under a growth of thistles 2 ft. high.

—

Lifting Canadian Import Restrictions a Spur to Trade

DETROIT, April 12—Reports coming from Ottawa telling of the lifting of restrictions on the importation of automobiles into Canada by the War Trades Board of Canada, if true, are going to cause a great boom in the export business of Detroit automobile makers. Customs officials at Windsor, Ont., Detroit's port of entry into the Dominion, have received no official notice of such action, however, and, in the meantime all war restrictions as pertaining to cars of the $1,250 class and over are still in full effect.

The effect of the lifting of the British war embargo on Canadian goods, thus giving the Canadian manufacturers practically free access to all parts of the British Empire, is already stimulating Canadian as well as United States automobile makers for renewed activities. Detroit manufacturers see in the lifting of the embargo an open road to the British market. This, coupled with the decision of the Crown customs officials at Windsor, who hold that an assembled car, even if assembled from parts made in the United States, may be considered a Canadian car if assembled by Canadian labor, is bringing many branch plants to Windsor and is causing Canadian part makers to plan plant extensions.

It is stated at the Border City Chamber of Commerce, Windsor, that a number of Detroit automotive factories are contemplating Canadian branches.

The Paige-Detroit Motor Car Co. has just announced its intention of establishing a Canadian assembly plant for its cars and trucks. R. D. McCain, traveling representative of the Paige Co., is in Canada looking over the situation and preparing data on the advisability of such a move.

Truck Delivery Possibilities in South America

BUENOS AIRES, April 1—Purchasing representatives have come from Chile to the United States to purchase 60 motor trucks to replace all horse carts in the delivery system of Valparaiso and Rio Santiago, Chile. In South American cities the municipal meat delivery has been generally carried on by horse vehicles, but since the start of the war there has been a growing sentiment in favor of motor trucks.

The city of Buenos Aires is a typical example of this practice, in which beef from municipal slaughter houses at one end of the city is delivered by horse carts to the retail butchers of the city. Buenos Aires uses from 220 to 250 horse carts in this service, and the delivery must be accomplished by 11 a. m. each day. At present these carts are owned by different concerns, and the thought is that they could all possibly be replaced by motor vehicles. What seems to be the greatest objection to the motor vehicle is that the work does not require the trucks for the entire day, and to use them eventually would mean employing them in some other work that portion of the day not needed for meat delivery. This calls for some interchangeable feature of bodies, which has not as yet been worked out successfully.

It was estimated recently that approximately 100 motor trucks of 3-ton capacity would be needed in this service in Buenos Aires alone, as approximately 310 tons of meat have to be delivered each day. The longest trips are 25 miles and the average would approximate 10 miles. Now that the war is over more attention is being given to this matter than formerly.

Exhibit at Venezuela

WASHINGTON, April 11—The National Exposition of Venezuela will be held May 15-June 1, and manufacturers of automobiles, motor trucks, farm tractors and parts and accessories will be permitted to exhibit their goods.

—

To Hold Pan-American Meeting

WASHINGTON, April 12—A meeting of the Pan-American commercial conference will be held here either late in May or early in June, and plans are being arranged by the Pan-American Union to invite commercial and financial experts to attend. It is expected that more than 1000 representatives of the various American republics will be present. Sessions will be held at the building of the Pan-American Union here.

—

Trade With German Austria Permitted

WASHINGTON, April 9—Automotive manufacturers can now export automotive products, excepting those of a military nature or character, into German Austria, according to announcement made by the War Trade Board. Any commodities exported must be intended solely to supply domestic needs in that country.

G. M. Proposes Plan for Savings

Will Set Aside Dollar for Dollar With Employees—Classes Mature in 5 Years

DETROIT, April 14—The General Motors Corp. has inaugurated a savings and investment plan for the benefit of employees of General Motors Corp. and subsidiary companies. At the annual meeting of stockholders to be held April 30 in Wilmington, Del., an amendment to the by-laws, calling for the operation of this plan, will be submitted. Only such stockholders as are on record at the close of business, April 9, are entitled to vote on the amendment. The plan has already been approved by the officers and directors. It aims to encourage and assist all employees in the saving and investment of money and to afford them opportunity to become stockholders and share in the development of the business. Excerpts from the plan follow:

All employees who have been in the employ of the corporation or its subsidiaries for 3 months or more are eligible to participate in the plan. Each employee shall have the right to pay into the savings fund each year an amount not to exceed 10 per cent of his wages or salary, and in no event shall the amount so paid exceed $300 per annum. Payments must be made in amounts of $5 or multiples thereof.

The corporation will also establish an Employers' Investment Fund, and will pay into such fund an amount equal to the total net payments made by the employees into the savings fund. The corporation will credit interest semi-annually at the rate of 6 per cent per annum upon all amounts paid into the funds.

The savings and investment funds will be divided into yearly classes, that is, a new class will be formed each year to be designated "Class of 1919," "Class of 1920," "Class of 1921," etc., and each class will mature 5 yr. from the date of its formation; thus the Class of 1919 will mature on Dec. 31, 1924, the Class of 1920 will mature on Dec. 31, 1925, etc.

The amounts paid into each respective class of the investment fund by the corporation will be credited over a period of 5 yr. to the individual employees participating in the corresponding classes in the Savings fund, that is to say:

One-fifth thereof will be credited 1 yr. after the date of the respective payments into the savings fund; one-fifth 2 yr. after the date of the respective payments into the savings fund and so forth.

It is the intention of the corporation to invest and reinvest the investment fund, preferably in common stock of the General Motors Corp., but if this is not readily obtainable, then in such other securities as in the discretion of the board of directors may seem advisable.

Statements will be rendered periodically by the corporation to each employee showing the status of his account in both the savings and investment funds.

Upon giving 15 days' previous written notice, an employee will be entitled to withdraw all or any part of the amount to his credit in both the savings and investment funds.

Withdrawals must be made in amounts of $5 or multiples thereof. In case of withdrawals, the amount so withdrawn by the employee shall be deducted from his most recent payments into the savings fund, and from the credits in the investment fund corresponding thereto, if any. In addition, he shall forfeit the payments made by the corporation into the investment fund corresponding to the payments withdrawn by him from the savings fund, except to the extent that such payments have been credited to him in the investment fund, and such forfeitures shall be charged against his investment fund account. Such forfeitures, however, shall not revert to the corporation but shall remain in the investment fund to be distributed among the employees at the maturity of the class as provided in Section "b" of paragraph 11 hereof.

In the event of the death of an employee, his legal representatives shall be entitled to receive immediately, in cash, the full amount standing to his credit in the savings fund plus a like amount to be paid from the investment fund.

As previously stated, each class will mature in 5 yr. after its formation and at the maturity of each class each employee will be entitled:

(a) To withdraw, in cash, the total amount to his credit in the savings fund; and

(b) Either to withdraw, in cash, the total amount to his credit in the investment fund or to receive his proportion of all securities and cash them in the investment fund of that class, including all forfeitures made by employees who have withdrawn money from the class during the 5-yr. period as provided in paragraph 9 hereof.

Each employee's proportion in distribution will be in the ratio that his total credit in the class bears to the total credit of all employees in the class at maturity thereof. In case of fractional shares, adjustment will be made in cash, valuing stock at current market prices.

Should an employee so desire, he may leave with the corporation all or any portion of the amount of cash he is entitled to receive upon the maturity of each class. The corporation will hold such cash subject to his right to withdraw upon 15 days' written notice and will credit his account with interest thereon, semi-annually, at the rate of 6 per cent per annum.

Likewise, should an employee so desire, the corporation will have the stock which he receives at the maturity of each class, transferred to his name and hold the certificates in safekeeping for his account, which certificates will be delivered to him on demand.

Money Refunded on Leaving Employ

If an employee leaves the service of the corporation of his own volition or is dismissed from such service, such employee will be paid in cash an amount equal to the same amount as said employee would receive if electing to withdraw said savings at that time. However, if the employee so desires, the corporation may in its discretion, if it determines his record to be satisfactory, continue such employee as a beneficiary under this plan to the extent that said employee's payments to the date of dismissal entitle him.

The corporation shall have the right to reinstate any employee who shall have lost his membership in any class if in its judgment the circumstances surrounding the loss of such membership are such as to warrant reinstatement.

While the corporation proposes a continuance of this plan from year to year, the directors shall have the right, from time to time, to modify or entirely repeal the plan, or to discontinue the receiving of payments hereunder, either temporarily or permanently. However, no modification of this plan shall in any way affect the rights of employees hereunder insofar as they may apply to payments theretofore made.

—

Jobbers to Hold Exhibit

CHICAGO, April 15—There will be a business exhibit of the Automotive Equipment Association in this city the latter part of October or first part of November in connection with the annual meeting, as was planned last year and dropped because of the war. This was decided at a meeting of the board of directors Tuesday. The matter of admitting other than members will be decided at the Hot Springs meeting June 2-6. Last year it was voted to admit outsiders if there was any space left after members were taken care of.

An exhibit committee was named, consisting of R. R. Englehart, Davenport, Iowa, chairman; N. H. Oliver, Chicago; Fred Campbell, St. Louis; R. A. Stranahan, Toledo; J. S. Proctor, Minneapolis; L. P. Halladay, Streator, Ill.

The name of the Ways and Means Committee was changed to Board of Governors. Discussion of the handling of the revenue tax was left for the Hot Springs meeting.

Industrial Relations Principles

U. S. Chamber of Commerce Takes Up Problem and Lays Down Thirteen Rules

WASHINGTON, April 14—Concrete realization of the new problems that employers must face is brought directly to them by means of a referendum vote on principles of industrial relations requested by the Chamber of Commerce of the United States. The Chamber has prepared a statement of 13 principles, following a study of industrial relations by a special committee. It is placing these 13 principles together with pros and cons before its members.

The conduct of industrial enterprise with regard to both employer and employee, adjustment of industrial relations, employment, organization, representation, wages, production and administration of employment and management of labor form the basis of these principles, which are as follows:

1. Industrial enterprise, as a source of livelihood for both employer and employee, should be so conducted that due consideration is given to the situation of all persons dependent upon it.
2. The public interest requires adjustment of industrial relations by peaceful methods.
3. Regularity and continuity of employment should be sought to the fullest extent possible and constitute a responsibility resting alike upon employers, wage earners, and the public.
4. The right of workers to organize is as clearly recognized as that of any other element or part of the community.
5. Industrial harmony and prosperity will be most effectually promoted by adequate representation of the parties in interest. Existing forms of representation should be carefully studied and availed of in so far as they may be found to have merit and are adaptable to the peculiar conditions in the various industries.
6. Whenever agreements are made with respect to industrial relations they should be faithfully observed.
7. Such agreements should contain provision for prompt and final interpretation in the event of controversy regarding meaning or application.
8. Wages should be adjusted with due regard to the purchasing power of the wage and to the right of every man to an opportunity to earn a living at fair wages, to reasonable hours of work and working conditions, to a decent home, and to the enjoyment of proper social conditions.
9. Fixing of a basic day as a device for increasing compensation is a subterfuge that should be condemned.
10. Efficient production in conjunction with adequate wages is essential to successful industry. Arbitrary restriction on output below reasonable standards is harmful to the interests of wage earners, employers, and the public and should not be permitted. Industry, efficiency and initiative, wherever found, should be encouraged and adequately rewarded, while indolence and indifference should be condemned.
11. Consideration of reduction in wages should not be reached until possibility of reduction of costs in all other directions has been exhausted.
12. Administration of employment and management of labor should be recognized as a distinct and important function of management and accorded its proper responsibility in administrative organization.
13. A system of national employment offices, with due provision for co-operation with existing state and municipal systems, can be made, under efficient management, and if conducted with due regard to the equal interests of employers and employees in its proper administration, a most helpful agency, but only if all appointments are made strictly subject to the Civil Service law and rules. Policies governing the conduct of a national system of employment offices should be determined in conjunction with advisory boards — national, state and local — equally representative of employers and employees.

Picture Range of Heavy Oil Engines for Variety of Uses

Joint Meeting of S. A. E. and Society of Mechanical Engineers Discusses Problems of Design, Including Ignition, Carburetion and Thermal Efficiency

NEW YORK, April 15—Various phases of the subject of heavy oil engines were illuminated at the joint meeting of the American Society of Mechanical Engineers, New York Branch, and the Society of Automotive Engineers, Metropolitan Section, which was held at the Automobile Club of America on April 9. Dr. Charles E. Lucke of Columbia University was in the chair, and led off with a general discussion of the subject. He said that each of the two societies represented at the meeting was interested in internal combustion engines. This engine is particularly adapted to transportation purposes, on account of the concentration of the liquid fuel, the fact that there is no residue left after the fuel burns, and that the engine lends itself to a great variety of forms, from the light aircraft engine on the one hand to the heavy marine engine on the other. The idea of the meeting was to give a sort of picture of the range involved in the application of heavy oil engines. There were two possible solutions of the problem of internal combustion engines, one being that of adapting the fuel to the engine and the other that of adapting the engine to the fuel. The fuels we are using range very widely in price, from about 30 cents per gallon for gasoline to a few cents per gallon for fuel oil. Then, there are a number of possible fuels which, though not extensively used at present, offer certain possibilities, such as alcohol and benzol. Generally speaking, the lighter the fuel the easier it is to make an engine that will handle it successfully, and vice versa. If we design our engines to consume a fuel of some particular kind the inevitable consequence is that, as the demand for that particular fuel rises, the price increases, and then someone else will make an engine that will burn a different fuel.

Gasoline and Kerosene Costs

In a paper prepared by E. W. Dean of the Bureau of Mines, and read at the meeting by J. S. Smoots, the statement was made that the manufacturing or processing cost is about the same for gasoline and kerosene. The selling cost is largely determined by the proportion betweeen the supply and demand, the cost of manufacture being small. Mr. Smoots exhibited samples of gas oil and of residuum fuel oil, the former being light in color and the latter dark.

Prof. H. Diederichs of Cornell University was to have given a talk on the development of the heavy oil engine, but was unable to be present, and so Prof. Lucke spoke on the subject instead. He said that in the early days of liquid fuel the light constituents of petroleum were a drug on the market. It was a very easy matter to make an engine that would run on these very volatile fuels, all that was necessary being to have a hole in the air pipe through which some of the liquid fuel could be drawn in with the air. As the supply of this volatile constituent decreased a somewhat heavier oil had to be used, and this required a carbureter and heat supply. With the pre-heating of the fuel and air there came a loss in volumetric efficiency. Next, new types of engines were introduced, in which some part of the combustion chamber wall was kept at a high temperature. This was known as the hot surface type of engine, and was developed chiefly in England. The fuel was injected in the form of a spray. Unfortunately this type of engine, in the early days, fouled up very quickly. The great difficulty, however, with the hot bulb or hot surface type of engine was that it was given to pre-ignition. This resulted in a low mean effective pressure. Fuel consumption also was excessive, which was largely due to the fact that the mixture was not homogeneous, some parts of the charge being practically pure air and other parts pure gas.

Injection of the fuel at the end of the compression stroke did away with the difficulty of pre-ignition and permitted of very much higher compression. Late injection, according to Dr. Lucke, is a fundamentally important feature. There are components of crude oil which have a decomposing temperature below their vaporizing temperature. If the spray is very fine, and if it is sufficiently well scattered through the air, then a solid fuel mixture or oil spray mixture will explode, and we can adapt the engine to any fuel we can get. The question then naturally arises, "Can the same sort of engine be developed for heavy work, such as the propulsion of motor ships and for light work such as motor tractors, trucks and automobiles. The speaker did not attempt to answer this question, but intimated that it was one of the problems of the future to adapt the automotive engine to heavier fuels.

Another one of the papers of the evening was by J. M. Hunt, research engineer of the Dayton Engineering Laboratories Co. Mr. Hunt started out by saying that his firm believed in preparedness, and it had looked to them that in a very few years there would not be fuel enough for the automobiles that would then be in use, so they got into the subject to find out what that would do to the ignition problem. The subject of effective ignition could really be divided up under four headings, namely, starting, distribution, vaporization and burning of fuel in the engine, and Mr. Hunt proceeded to discuss these four problems in succession. The problem of starting is not confined to getting a couple of explosions in the cylinder, but getting the cylinder up to its normal temperature. A pre-heater, used to pre-heat the inlet header, would give the desired result, and Mr. Hunt referred to some experiments with the Good pre-heater, which had been described by Dr. Lucke in a paper read before the S. A. E. some two years ago. Another method of solving the problem of starting was to carry two different fuels, a light fuel for starting and a heavy fuel for general running. Problems of distribution are encountered only in multi-cylinder engines. Proper distribution can be attended to after the charge has left the carbureter, and it seems best to incorporate the vaporizing device in the engine itself. The Good pre-heater previously referred to has been extensively tested on a Ford car, fitted with a kerosene carbureter, which has been run 20,000 miles in two years. During this time there has been no mechanical trouble, though it has been necessary to decarbonize the cylinders and to renew the crankcase oil slightly more frequently. The pre-heater has also been tested on a Buick car, which has been run about 12,000 miles to date.

Problems of Vaporization

Vaporization can be discussed under two headings, viz., loss in volumetric efficiency due to heating and the necessity for scrubbing the air against a rough surface. This scrubbing of the air means a further loss in volumetric efficiency, and consequently in the horsepower output.

When it comes to the burning of heavy fuel in an automobile type engine, the most characteristic feature is that the engine is apt to develop a knock. This leads us to the question of what a knock is. It was formerly supposed that a knock was generally due to pre-ignition, but this theory was disproved by experiments at the Dayton Laboratory, and the fact established that knocking is due to a sort of deterioration. Mr. Hunt said that if we want to get rid of crankcase oil pollution, we shall have to raise the temperature of the combustion chamber still higher, and this will further reduce the volumetric efficiency. It will undoubtedly be necessary before long, to devise automotive engines that will operate on gas oil. What is really needed is a sort of priorities board which will tell us just what percentage of all the fuel available, say 5 years hence, can be had for automotive apparatus.

A paper by Mr. Goldingham of the De La Vergne Refrigerating Co., on the heated metal type of heavy oil engine, was read by the chairman. Mr. Goldingham said that this type of engine was often erroneously called a semi-Diesel. Twenty years ago a British manufacturer of internal combustion engines offered a prize to any employee who could produce a heavy oil engine which would run continuously for 10 hours without stoppage. Now it was a common experience to have engines of the heated metal type

operate continuously for six months without stoppage. Great improvements had been made in this type of engine in recent years, which might be summarized briefly under the following headings: (1) More thorough atomization of the fuel, which was injected either by air pressure, or by the solid or mechanical method; (2) improved construction of the vaporizing chamber; (3) force feed oiling; (4) correctly designed air starting mechanism; (5) improvement of the vaporizor lamp.

The rest of the papers of the evening dealt chiefly with the application of heavy oil engines to the wooden ships of the U. S. Emergency Fleet Corporation during the war. Most of the engines used were of the hot-surface type, and it appears that considerable trouble was experienced, which, however, was ascribed to causes not directly connected with the engines. For instance, much green timber was used in the construction of these ships, and the engine bearers often would warp out of place to such an extent that the engine supports would break. Also, it was necessary to get a great many engineers for tending to these engines, and as no experienced men were available, green hands had to be employed.

National Assn. of Truck Sales Managers to Continue

PHILADELPHIA, April 15—The National Association of Motor Truck Sales Managers will continue as a separate body and devote its energies and attention to the problems of merchandising trucks, as hitherto. This decision was reached at the convention of the association held at the Bellevue-Stratford Hotel on Friday and Saturday, after careful consideration of many proposals and suggestions to do otherwise, and to cast its lot, through affiliations, with other bodies.

It was also decided to appoint a committee to take up the question of organizing an association of truck dealers. The committee will determine whether it will be better to strive for the results which such a dealers' organization would yield through a separate truck dealers' association or through the co-operation of the sales managers' association with the National Automobile Dealers' Association. This committee will report at the next convention, which will be held in Detroit. Future meetings of the association will be purely executive in character. They will be devoted solely to discussion of truck-selling problems.

New members were elected to the association as follows: The Vim Motor Truck Co., Fulton Motor Truck Co., Noble Truck Co., Parker Motor Truck Co., Menominee Motor Truck Co., J. C. Wilson Co., Velie Motors Corp., Canadian Ford Motor Truck Co. and Corbitt Motor Truck Co.

Reo Returns to Pre-War Hours

LANSING, April 14—The Reo Motor Car Co. will return to its pre-war working schedule April 19, calling for 9 hours a day with half day Saturdays. During the war period it operated on a 10-hr. schedule.

Sees Possibilities in Turbines

Dake Believes They Hold More Promise Than Do Any Reciprocating Engines

CHICAGO, April 12—At the meeting of the Mid-West Section of the S. A. E., yesterday, the possibilities of steam and gas turbines for vehicle propulsion were discussed in a paper presented by Charles W. Dake, chief engineer of the Pyle-National Co., manufacturers of steam turbines for train lighting. Mr. Dake has spent many years in designing turbines of small size and believes that the turbine offers more for the steam-driven vehicle than does the steam engine.

The steam turbine has many features that make it particularly fitted for the propulsion of motor vehicles, said Dake. The turbine will operate perfectly under initial steam pressures and temperatures of superheat far higher than that under which is it possible to operate any other type of fluid motor for the reason that there are no moving surfaces contracting stationary surfaces within the turbine structure, thus taking advantage of the efficiency gained by the use of high pressures and high superheat. Due to the absence of the friction within the turbine, it is not necessary that internal lubrication be provided, and by the elimination of internal lubrication, the exhaust steam is free from oils and greases; consequently the water of the condensed exhaust steam from the turbine can be returned to the steam generator (boiler) without fear of injury thereto.

The turbine, being a high speed machine, requires a system of reduction gearing. This can readily be accomplished with but slight power loss. A pair of properly generated herring bone gears having a reduction ratio of 10 to 1 has a power loss less than 1 per cent.

While the steam turbine can be readily made reversible, due to its high speed and the time required to bring the rotor at rest and start it revolving in a reverse direction, it is advisable to provide gearing for this purpose.

Unlike the reciprocating engine, the efficiency of the steam turbine remains constant throughout its life. This is due to the fact that no packing is required to prevent leakage of high pressure steam and the absence of wear to parts operating under the steam pressures and actions.

The mounting of a turbine rotor in its bearings and the lubrication of the bearings is very much more simple than is possible with either the reciprocating steam or gasoline engine. Ball bearings lend themselves admirably to high speed turbine operation. The size bearings required for a 40-hp. turbine of the type described below can be operated successfully at speeds as high as 60,000 r.p.m. or peripheral velocities of the turbine rotor of approximately 1832 ft. per second.

The steam turbine is commonly thought of as a constant speed and constant load machine, which, in order to obtain high efficiency, should be operated at high velocities and under constant pressure. This is true of most of the present designs of turbines.

However, with proper design and construction, the turbine will give a high efficiency at greatly varying speeds, loads and pressures. This is accomplished by so designing the turbine that the velocity of the steam jets or motive fluid which exceeds the velocity of the rotor shall be entirely absorbed by the rotor's steam passages, and the steam will come to rest in relation to the movement of the rotor at the instant of its exit, regardless of the velocity of the rotor or the velocity of the steam jet.

The dimensions of the rotor, exclusive of the shaft, for a 40-hp. turbine designed to operate under 1500 lb. gage pressure of steam, or rather the velocities derived from that pressure, would be 7 in. in diameter and 4 in. long, and would weigh but 7 lb. The complete turbine, exclusive of external fittings, would weigh less than ¾ lb. per brake horsepower.

The torque delivered to the turbine rotor of the type in mind increases with the decrease in velocity of the rotor, and decreases with the increase of the velocity. In other words, the velocity of the steam jet is absorbed by the rotor regardless of whether it is revolving slowly, or at top speed; therefore, a vehicle propelled by a steam turbine, as above, can be started from rest and will traverse grades at reduced speeds and as well, if not better, than will one propelled by a reciprocating steam engine.

There is at the present time considerable activity among inventors and engineers to produce a turbine that can be operated by the impulse of the explosive combustion of such a mixture as is used in the reciprocating internal combustion engine. This activity, however, seems to be confined to only types and designs of turbines in use at the present time and no effort, it appears, is given to lines of new thought. This, in the writer's opinion, is a mistake, for it is impossible to produce a turbine employing buckets which will withstand the impact of high temperatures such as are delivered by the gasses of combustion.

However, there is under process of development a turbine of great promise designed to overcome many present obstacles, and to provide higher efficiency than is given by the gas engine. Unfortunately, the writer is not at liberty to disclose the details of this machine owing to the conditions of the patent rights both in this country and abroad, which might be jeopardized by so doing. Nevertheless, a brief description of its possibilities and operation will be more in order than its construction.

The flexibility of this turbine is as great as that of the steam turbine, which I have previously referred to. It will operate at any speed from one revolution per minute to the bursting speed of the rotor. The compression of the gas, which is very high—at times reaching 2000 lb. per square inch—is accomplished without mechanical means, and this while the turbine is at rest.

The initial ignition is accomplished by means of a spark from a battery of two dry cells and then continued by means of a hot tube, which, if desired, may be kept hot during stops and for long periods of time. Regardless of weather conditions, the time required to start the turbine is almost instantaneous, and in no case would it be greater than 30 seconds. The turbine can be started from rest, doing away with all starting mechanisms.

The starting torque is greater than that of the reciprocating steam engine of equal power, operating under permissible steam pressures. A 40-hp. turbine complete, including ignition system, gas compression means, controls and shaft coupling, will develop one actual brake horsepower for each 3 lb. of its weight when operated at permissible speeds.

William J. H. Strong of the Strong Engineering Co., Chicago, the other speaker of the evening, presented the plans that were developed for the Government for steam power plants in airplanes. Mr. Strong's company designed for the government aviation officials a steam plant which at 15,000 ft. altitude weighed about 9 or 10 lb. This included engine, boiler, condensing system, auxiliary pumps and the electrical equipment, the horsepower of the plant being 580. The engine operates on the uniflow principle, and in appearance resembles the King-Bugatti. The boiler is a water tube type, having the individual tubes welded into sections and the sections welded to headers.

$3,199,828 Waste Materials Sold by Army

WASHINGTON, April 11—Waste materials sold by the army during the eight months ending Feb. 9, 1918, totaled $3,199,828, and included:

British Westinghouse Control to Vickers

Through Absorption of Metropolitan Carriage Company in Deal Involving $132,500,000

LONDON, April 1—One of the biggest business deals in which British interests have figured for some time is the absorption by what is known as the Vickers interests of the Metropolitan Carriage & Wagon Co. The event here referred to is not of interest to the motor trade in itself, but the latter company recently acquired a controlling interest in the British Westinghouse Co., Manchester. This company, aiming at a variety of output, is interested in the British replica of the Pittsburgh company's dynamo and starter for vehicles.

This new step by the Vickers Co. through a subsidiary company in their own group, concerned with the B.L.I.C. (late Bosch) magneto, dynamo and starter, is likely to involve the cessation of the corresponding Westinghouse lines. Otherwise there would be virtual competition between these rival wares.

The B.L.I.C. manufacturing side is being transferred from London to a factory in Birmingham, until recently used by the Electric & Ordnance Accessories Co. Up to this time this company has built the Wolseley Co.'s Stellite car, the complete manufacture of which, however, is being arranged for in the Wolseley Co.'s now much extended factory.

The amalgamation or absorption of the Metropolitan Carriage company's business involves a capital of $132,500,000, which will give some idea of the vast financial resources of the Vickers group. Many people read into this expansion of the Vickers interests the intention to be prepared for quitting armaments manufacture, if necessary, in favor of a wholesale concentration on peace industries. By the way, it is reported that the Wolseley and Vickers interests have arranged an alliance with a Japanese engineering company, who will build Wolseley cars for its Far East territories.

New English Insurance Company Emphasizes Service

LONDON, April 1—The Motor Union Insurance Co., one of the leading insurance organizations in writing motor car insurance, has entered the garage and repairshop field. This move comes as retaliation to the Motor Trade Association, which some years ago formed an insurance company as an independent venture for the benefit of its members as well as for the revenue obtained. As the membership of the M. T. A. is large and increasing, the move of this new insurance company means that the number of garages and repairshops will increase.

The insurance company has chosen the subject of service as one of the requirements of its garages and repairshops. Hitherto service has been a sort of counsel of perfection, but the Motor Union Insurance Co.'s scheme makes it obligatory, and also imposes the condition that the garages favored with its patronage shall conform to its standard of equipment and facilities for repairing, etc.

The alternative to these conditions will be for the local dealer to send his work to one of the Union's pivotal depots, as they are to be called, and he will be allowed a trade abatement at a fixed rate or per cent off the price levied on private customers.

Each pivotal depot will be a center for an associated group of repairers and dealers, approved by the Union Insurance Co., which seems to imply that membership of the M. T. A. will be a ban on membership in the new company's pivotal scheme.

Public and private motorists will be the gainers by the proposed competition, much of it centering in the quality of service benefits of the competing parties. Hitherto there can be no gainsaying the fact that the M. T. A. has been regarded by ordinary motorists as being more concerned in pushing up and maintaining prices than in securing a common standard of high grade service. The new issue seems a favorable opportunity to set this matter right.

English Truck Company Adds 6-Cylinder Car

LONDON, April 1—The Straker-Squire Co., manufacturer of the Straker-Squire truck, has purchased one of the Government war factories and plans to concentrate on the manufacture of a 6-cylinder car in addition to one or more sizes of trucks.

The new Straker-Squire "six" with cylinders 80 x 130 has them as separate castings. The reason for reverting to the separate cylinder as compared to the block type is that there is not so much danger of hot spots developing in the individual cylinder as in the block type due to difficulties incidental to misplaced cores and the irregular flow of metal in the block. The car has dial on the dash showing the speed of crankshaft rotation and the speedometer is driven from the gear-box.

The factory purchased occupies 14 acres and was bought at $700,000, which is more than the original cost of construction and equipment by the Government. Formerly the Straker-Squire Co. had a factory at Bristol which was recently sold to the Cosmos Engineering Co., Ltd., which concern at that time had interests in the 6-cylinder car and in reality developed it. The Cosmos company entirely disposed of its interests and is now developing a new car employing a radial engine which also carries several other earmarks of airplane development. Roy Fedden, who designed the Straker-Squire 6-cylinder car, remains with the Cosmos Company.

Aluminum Castings Operations

MILWAUKEE, April 12—The Aluminum Castings Co., Cleveland, probably will discontinue its Manitowoc plant on May 1 and divide the operation between its works at Cleveland and Detroit.

No Guarantee for English Tires

Solid Tires to Be Judged by Performance, Not Guarantee, Is Reason for Decision

LONDON, April 1—The abandonment of a guarantee on solid rubber tires by the British tire makers has naturally aroused a good deal of criticism, and many business organizations do not know just why this step was taken. The guarantee of 10,000 miles on these tires had its origin in the early days of the motor truck when tire costs were about as fluctuating as the mileage was varied. At that period, too, the initial cost of a set of truck tires was a much more serious item than latterly, being often sufficient, in the event of a premature collapse of two or more of a set, to preclude the vehicle concerned from showing a profit on a year's turnover. It is now frequently the experience of users that a set of tires go far beyond the mileage guaranteed.

Reasons assigned for the decision to withdraw the guarantee of mileage are:

That it leads users to expect the guaranteed mileage and nothing more; that it tends towards the production of a stereotyped tire, just capable of fulfilling the guarantee and no more; encourages carelessness on the part of the driver, who regards the responsibility for the tire as solely that of the maker; and that it is necessarily hedged about by technical conditions and stipulations, which in some circumstances are difficult to see.

The British Rubber Tire Manufacturers' Association for the future will be content to allow their products to be judged by the service given as distinct from merely guaranteed.

Considerable assistance in regard to these points is expected from systematic collective research and the British Rubber & Tire Manufacturers' Research Association, which is now in process of formation.

Twin City 12-20 Kerosene Tractor

(*Continued from page 839*)

worm and sector type of steering gear of generous proportions is mounted on the right-hand side of the transmission case, and runs in oil. The size of the steering wheels, and a liberal gear reduction, coupled with the light weight of the tractor and the weight distribution, make it a very easy machine to handle in the field. Stops are provided on the front wheel tie rod to limit the maximum turning angle of the front wheels.

The belt pulley is 16 in. in diameter and has a 6-in. face. It is mounted on the left-hand end of the first countershaft, and is removable. The linear belt speed is 2700 ft. per minute.

The front end of the tractor is supported through coil springs upon a drop-forged steel front axle of I section, with reversed Lemoine steering heads. This axle swings vertically on a center pivot. The front wheels have rolled-steel flanged rim 34 in. in diameter and 6 in. wide. The wheelbase is 84 in., and the weight of the tractor stripped is 4000 lb.

Field tests have proved that a load of 35 per cent in excess of the rating can be easily sustained, and the engine when running at its governed speed of 1000 r.p.m. will develop a maximum of 35 b.hp. on kerosene.

Men of the Industry

Changes in Personnel and Position

Dawson to Manage Gary Truck

GARY, IND., April 12—A number of important additions have been made to the personnel of the Gary Motor Truck Co., although the officers remain unchanged. Frank Dawson has been appointed general manager of the company. He was formerly factory manager of the Randolph Motor Truck Co., Chicago; was later with the Mogul Truck Co., St. Louis, and in 1916 was appointed factory manager for the Master Truck Co. E. Von Rakowski has been appointed chief engineer, and has been closely associated with Dawson for several years past. Theodore B. W. Zumstein has entered the sales department. The Gary company has just closed a contract with the Cooper Motor Co., Kansas City, with branches in Omaha, Tulsa and other western and southwestern cities for more than a million dollars' worth of Gary trucks, to be delivered within the next 12 months. The company will operate as a factory branch and will have exclusive sales of Gary trucks in Missouri, Arkansas, Oklahoma, western Iowa, Nebraska and South Dakota.

Frank W. Haskell, president of the Carborundum Co., Niagara Falls, N. Y., died April 2 at Daytona, Fla. His death was due to heart failure.

J. G. Lude, for six years purchasing agent of the Falls Motors Corp., Sheboygan Falls, Wis., has resigned to become assistant general manager of the Lewis Steel Products Co., Toledo. Angelo R. Clas, formerly secretary-treasurer of the Falls company, has been president and general manager of the Lewis company since Jan. 1.

C. H. Margell, formerly assistant general manager of the Monarch Governor Co., Detroit, has become associated with LeRoi Co., maker of car and tractor engines, Milwaukee, as assistant chief inspector.

G. H. Hamilton, Milwaukee, has been appointed manager of the new export department of the Federal Rubber Co., Cudahy, Wis., which has been established, with headquarters at the Federal company's eastern headquarters, 38 and 40 West Sixty-second Street, New York City. The export business heretofore was handled through the general offices at Cudahy.

R. T. West has been appointed sales manager for the Hession Tiller & Tractor Corp., manufacturer of the Wheat tractor.

Duplex Adds Sales Engineers to Staff

BROOKLYN, N. Y., April 11—V. N. Barton has been added to the sales engineering department of the Duplex Engine Governor Co., and will cover Pennsylvania and the southern states. R. Weston Doherty has a similar position covering New York, New Jersey and New England territories.

Clyde Export Representative on Business Tour

NEW YORK, April 11—In order to keep more closely in touch with their foreign dealers and conditions in the Far East, P. W. Gaylor has left on a trip through that territory for the Clyde Cars Co. He will visit China, Japan, Siam, the Federated Malay States, Straits Settlements, Dutch East Indies, India, etc.

Horning to Speak at Detroit

DETROIT, April 12—At the April 25 meeting of the Detroit Section of the Society of Automotive Engineers H. L. Horning, chief engineer and general manager of the Waukesha Engine Co., Waukesha, Wis., will deliver a talk entitled "Tractor Engines." The meeting will be held in the ballroom of the Hotel Pontchartrain.

John A. Glaspy, who has been manager of the Kelly-Springfield Tire Co. at its Milwaukee branch, has resigned to become assistant general sales manager of the International India Rubber Corp., South Bend.

C. W. Whitston, until recently sales manager of the Panhard Motor Truck Co. of Grand Haven, Mich., has been made district sales manager for the Nelson Motor Truck Co., Saginaw. He will handle the Southwest territory, with headquarters in Los Angeles, Cal.

J. F. Fernihough, formerly district representative for the Bethlehem Motor Truck Co. in the Middle West, will be in charge of the Northwest territory sales of the Nelson Motor Truck Co. Chicago will be his headquarters.

Raymond A. Long, chief engineer of the Columbia Motors Co., who for two years was engaged in Government work, assisting in designing the Militor truck, has returned to Detroit and resumed his duties with the Columbia company.

C. K. Sincebaugh has severed his connection as sales engineer with the tractor equipment division of the Remy Electric Co., and is associated with the Rex Machine Co., Chicago, as general manager.

H. H. Burger has taken charge of the Stewart Products Co., Cleveland, as manager. This company, which has been operated as a Stewart-Warner factory branch, has been changed to a service station.

National Designer Is Back

INDIANAPOLIS, IND., April 12—Lieut.-Col. William Guy Wall has returned to assume his connection as vice-president and chief engineer of the National Motor Car & Vehicle Corp. He has been chief engineer of the National factory for 15 years. He headed that section of the ordnance department charged with design, construction and maintenance of armored cars, tanks, ammunition trucks and artillery tractors.

Allen of Austin Co. Returns to England

NEW YORK, April 15—C. H. Allen, manager of the sheet metal department of the Austin Co., Birmingham, England, and who has been in this country for several weeks purchasing presses for body manufacturers in production quantities, returned to England this week. Mr. Allen has been in sheet metal work for 20 years and has been making a complete study of the different American plants in addition to having ordered 7 special presses for body production work. These are to be used in connection with the production work of Austin Model 20, one of the British war cars.

Pogue Now With Division of Mineral Technology

WASHINGTON, D. C., April 12—Joseph E. Pogue, formerly connected with the Bureau of Oil Conservation, which has recently ceased activities, is now connected with the Division of Mineral Technology in the United States National Museum. This division is carrying on educational work with special reference to the mineral industry. Mr. Pogue, while with the Bureau of Oil Conservation, gave much attention to the question of possible supply of crude oil.

Edge to Re-enter British Industry

LONDON, April 1—S. F. Edge, one of the best known figures in the British motor industry, until his withdrawal 7 years ago from the Napier organization, is expected to return to the industry now that his 7 years' contract to refrain from enterprise in the motor trade has expired. He is expected to take up the manufacture of a fully equipped car that will list at $1500.

C. F. Rouze, formerly sales manager for the Knox-Martin Tractor Co., has been placed in charge of the sales promotion department of the General Motors Truck Co., Pontiac.

Charles Kuehn, who has been with the Packard advertising department for a number of years, has been put in charge of advertising and sales promotion department of the Packard Detroit branch.

K. W. Macrae, for the past 5 years in charge of the Canadian sales for the Saxon Motor Car Corp., has tendered his resignation, to take effect at once.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Chalkis Will Make Lock Washers

DETROIT, April 12—The Chalkis Manufacturing Co., organized during the war by Hugh Chalmers and W. C. Kiser to manufacture guns for the Government, and whose war operations were brought to a sudden halt before they were well started by the signing of the armistice, will shortly enter the automotive parts field. The company will start the production of lock washers within 30 days, and later other lines will be added.

The present Chalkis plant on Mack Avenue has been sold. Nearly $500,000 worth of machinery designed for munition work will revert to the Government. The Detroit Culto-Tractor Co. first proposed locating in the Chalkis plant, but this plan was abandoned some time ago.

The Chalkis Co. will move into the down-town district, having leased the sixth and seventh floors of a new Power building. At a recent election of officers Hugh Chalmers was elected president; W. C. Kiser, vice-president and general manager, and A. W. Lott, secretary and treasurer. Mr. Lott comes to the Chalkis company from the office of A. W. Wallace Co., brokers.

International Rubber to Increase Output 200 Per Cent

SOUTH BEND, IND., April 12—G. W. Odell was elected president and treasurer of the International India Rubber Corp. at a meeting of the board of directors, and he will also continue the general management of the company. Other officers are: Vice-president, Peter E. Studebaker; secretary, J. A. Bennett. The officers and C. W. Truxell and J. W. Ridge form the board of directors.

It was decided at the meeting to go ahead with the plans made last year to extend the length of the main building to 967 ft. This extension with additional equipment will increase the output of the plant about 200 per cent.

Arrow Grip Capital Increased to $500,000

GLENS FALLS, N. Y., April 12—The Arrow Grip Mfg. Co., Inc., has increased its capital from $100,000 to $500,000, and is at present erecting a new factory here.

Aluminum Goods Spending $1,250,000 on Plant Additions

MANITOWOC, WIS., April 14—The Aluminum Goods Mfg. Co., with branch factories in Two Rivers, Wis., and Newark, N. J., will this year invest approximately $1,250,000 in the enlargement of the Two Rivers and Manitowoc plants. Contracts have been awarded for three new buildings at Two Rivers, and another contract will be awarded for a 5-story addition, 160 x 280 ft., here during the coming week. The Two Rivers buildings are: Plant No. 1, 50 x 320 ft., 3 stories; plant No. 4, 60 x 300 ft., 4 stories; warehouse, 44 x 137 ft., 3 stories. The present works here and at Two Rivers each employs more than 1500 operatives.

Japanese Truck Manufacturer Organized

DETROIT, April 11—A Japanese company is being organized to manufacture motor trucks in that country. Through Gaston, Williams & Wigmore, New York City, this company is placing orders with Detroit automotive firms for parts for several experimental trucks which it proposes to assemble at once. The company, with $2,500,000 capital, is buying engines, transmissions, steering gears, wheels, clutches and other parts. Cutting, Armstrong & Smith and the Grey Motor Co. of this city have received preliminary orders for this material and are preparing shipments for New York.

Swedish Company Enlarges Plant

WASHINGTON, April 11—The Scania Vabis Works, Malmo, Sweden, have completed additions to their factory enabling them to manufacture complete automobiles. This company, which manufactures gas engines and electric motors, turned out a production in 1917 valued at $1,622,000.

G. M. Absorbs Michigan Crankshaft

LANSING, April 12—The Michigan Crankshaft Co. is the latest organization to be added to the General Motors holdings. By this deal the National Engineering Co., Saginaw, which was owned by the Michigan Crankshaft Co., automatically becomes General Motors property. Much of the grinding work of Lansing General Motors companies will be handled in the new plant.

The Michigan Crankshaft Co. was organized ten years ago with a capitalization of $50,000. This was later increased to $200,000. With the additional capital it bought the National Engineering Co. at Saginaw. J. W. Wilford will remain at the head of the company, and will continue the management of both Lansing and Saginaw plants.

Branch of General Asbestos Moved

CHICAGO, April 12—The Chicago branch of the General Asbestos & Rubber Co. has been moved into new and larger quarters at 14 North Franklin Street.

Porter-Cable Buys Lathe Company

SYRACUSE, April 12—The Porter-Cable Machine Co. has purchased the business of the Mulliner-Enlund Tool Co. and will move the latter company's equipment to the Porter-Cable plant. The production of Mulliner lathes will be continued. Both Mulliner and Enlund will be connected with the Porter-Cable organization.

Moon Victory Model in Production

ST. LOUIS, April 14—The Moon Motor Car Co. is now in production on its new Victory model, which is to sell at $1,685, and which was first exhibited at the St. Louis show. It is a 5-passenger, 118-in. wheelbase car, equipped with a 3¼ x 4 6-cylinder Continental engine.

New Jumbo Model

SAGINAW, MICH., April 11—The Nelson Motor Truck Co. is getting into production on a new 2-ton tractor. The tractor has a 108-in. wheelbase. All specifications are the same as the regular Jumbo truck. The tractor will be marketed in connection with 3 to 5 and 5 to 7-ton semi-trailers as a 6-wheel unit for heavy-duty work.

This company also proposes to bring out a new 3½-ton truck in about 90 days. The new truck will have a T-V Buda engine, Clark axles, four-speed transmission, unit power plant with drive torque rods and a pressed-steel frame. The manufacture of the regular 2-ton model will be continued.

New 1½-Ton Selden Ready for Delivery

ROCHESTER, April 14—The Selden Truck Sales Co. will commence deliveries of its new 1½-ton worm-drive model on April 21. It is equipped with a 3¾ x 5 Continental Red Seal engine with high tension magneto and Stromberg carbureter. It will sell for $2,185. Tires are 34 x 3½ single, front, and 34 x 5 single, rear. Pneumatic equipment is extra. The wheelbase is 140 in. and the length of the loading space 9 ft. 6 in.

Shipping Board to Use Wisconsin Engine Plant

RACINE, WIS., April 14—A lease taken by the United States Shipping Board, Emergency Fleet Corp., of the plant of the defunct Wisconsin Engine Co. at Corliss, will not affect the possession held by the Corliss Motor Truck Co. of one of the group of buildings which it uses as a factory. The Shipping Board will use the plant for assembling, storage and shipping vessel parts, machinery and equipment. The lease is for 5 years.

National Tractor Now GO

CEDAR RAPIDS, April 14—The National Tractor Co. has changed the name of its product from National to GO, and is bringing out a new machine similar to its older model but equipped with a Waukesha 4½ x 5¾ engine.

D. & L. Will Make Mechanical Appliances

MILWAUKEE, WIS., April 14—The D. & L. Mfg. Co. has been organized at Milwaukee with an authorized capital stock of $50,000 to manufacture tools, dies, fixtures and general mechanical appliances. The incorporators are Henry C. Dorn and Herman L. Luedke.

Calendar

SHOWS

April 16-19 — Waynesburg, Pa. Automobile Dealers' Assn. of Greene Co., Armory. Frank L. Hoover, Mgr.

May 10-17—Bristol, Va.-Tenn. Cars, Trucks, Tractors, Airplanes and Accessories. Bristol Chamber of Commerce. C. W. Roberts, Manager.

May 15-June 1—Venezuela. National Exhibit of Venezuela.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

*Oct. 15—Paris. Grand Palais, International Automobile Mfrs. Congress.

Nov. 7-15 — London. Olympia Motor Car Exhibition—Society of Motor Mfrs. and Trades.

December—Brussels. International Automobile Mfrs. Congress.

January—New York. International Automobile Mfrs. Congress.

February — Chicago. International Automobile Mfrs. Congress.

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

April 23 - 25 — Walla Walla, Wash. Sectional Tractor Demonstrations.

May 5—Sacramento, Cal. Sectional Tractor Demonstrations, Demonstration Field.

June — Denver, Col. Sectional Tractor Demonstrations.

July—Wichita, Kan., Automotive Committee of National Implement Assn.

Aug. 18—Aberdeen, S. D. Sectional Tractor Demonstrations.

RACES

April 24—San Bernardino, Cal. Rim of the World Hill Climb.

†May 17—Uniontown, Pa., probably 112½ miles.

†May 31—Indianapolis, Indianapolis Motor Speedway Assn., 500 miles.

*June 14—Sheepshead Bay, L. I. Speedway race.

*July 5—Cincinnati, O., Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15—Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

†Sanctioned.
*Tentative dates.

CONVENTIONS

April 24-26—Chicago — National Foreign Trade Council. Sixth National Foreign Trade Convention. Congress Hotel.

April 28-May 1—St. Louis, Mo. Chamber of Commerce of United States Convention.

May 1-June 1 — Atlantic City, N. J.—Pan-American Aeronautic Convention and Exhibition — Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

May—Washington, Pan-American Commercial Conference, Pan-American Union Building.

June 23-28—S. A. E. Mid-summer Meeting.

Sept. 22-24—Philadelphia, Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

Allen Motor Co. to Boost Production

COLUMBUS, OHIO, April 14.—The Allen Motor Co., of Fostoria and Bucyrus, Ohio, will move to Columbus. It is a $3,000,000 concern with five plants in operation for six years. Its record output is 5000 cars made in 1916 and its pay-roll aggregates $1,000,000 annually. The company hopes to boost its production to 20,000 after it is located in its new Columbus plants.

The factories formerly occupied by the Columbus Buggy Co., will be occupied by the Allen Co. The Scioto Rubber Co. is to be absorbed in the deal. The Allen Motor Co. is at present employing 500 men.

Fordson Dealers Get More

DES MOINES, April 15—The price of the Fordson in Iowa, Nebraska and South Dakota, the territory of the Herring Motor Co., has been advanced to $926, f.o.b. Dearborn, Mich., plus handling charges. The dealer price remains as before, giving the dealer about $40 additional in lieu of an increase in the discount. The increase makes the discount from 15 to 17 per cent.

Kelsey Wheel Addition

WINDSOR, ONT., April 12—A building permit has been granted to the Kelsey Wheel Co. for the erection of an addition to the plant.

Haynes to Have Capacity for 50 a Day

KOKOMO, IND., April 12—Work is to be begun immediately by the Haynes Automobile Co. on the erection of a building 150 x 500 ft., 4 stories high, and of a new forge shop, 70 x 180, following the recent increase of its capital from $3,500,000 to $5,000,000 through the issue of $1,500,000 preferred stock at 7 per cent. Other improvements in the plant are to be made, and when all the work is completed in the fall the normal capacity of the plant will be increased to about 50 cars a day.

General Motors Truck Co. Finishes War Work

PONTIAC, April 14—The General Motors Truck Co. finished its war work in January, when 500 trucks were turned over to the Government, and is now getting fair production for commercial sales. An average of 30 machines is being turned out daily, but plans call for a material increase in production during May and June. This company, having extended its manufacturing facilities last year, does not come in for a split of the General Motors expansion budget.

Maxwell to Retire $145,244

NEW YORK, April 15—The Maxwell Motor Co. is shortly to retire $145,244 of its first preferred stock. This amount is now held by the Central Union Trust Co. of New York as trustee for the company. On May 16 the trust company will receive bids for the retirement of not to exceed 2880 shares of stock.

Eagle Officers Changed

APPLETON, WIS., April 14—Frank Saiberlich, president and founder of the Eagle Mfg. Co., maker of farm tractors, gas engines, etc., has disposed of his interest and will retire. His brother, Oscar, also has sold his third interest, but Edward Saiberlich, secretary and treasurer, remains a stockholder and officer. The new interests are represented by August Knueppel, Nicholas Dohr and Matt Rossmeissl, all of whom are large stockholders in the George Walters Brewing Co.

Dorr-Miller Differential Acquires Tool Company

NEW YORK, April 12—The Dorr-Miller Differential Co. has purchased the interests and plant of the Ward Machine & Tool Co., Detroit, and will correspondingly increase its manufacturing facilities. A part of the plant will be devoted entirely to the special differential for Fords. This type is to be distributed through county agents who are now being appointed.

Columbia to Double Production

DETROIT, April 12—The Columbia Motors Co., while working on plans for a new factory plant, will not build this year but will lease buildings providing sufficient facilities to permit the company to double its production. Extension plans for doubling its floor space would add 100,000 sq. ft. It has orders for 1300 cars and contemplates producing 3000 passenger cars this year.

Maxwell Completes Last Tractor

DETROIT, April 11—The last military tractor was completed by the Maxwell Motor Co. last week, and the company is getting back into full peace production of cars. The machine finished last week was No. 2000, and was a 5-ton model. The original contract called for 3000 tractors, but the early termination of the war cut this number by one-third. This company has already run its passenger car production up to 220 daily.

New Torbensen Axle Officials

CLEVELAND, April 12—J. O. Eaton was elected president, with two vice-presidents, W. J. Baxter and C. F. Hepburn, at the directors' meeting of the Torbensen Axle Co. Other officers are: Chairman of the board, V. V. Torbensen; treasurer, F. A. Buchda; secretary, A. H. Ide; assistant secretary, R. C. Hyatt, and comptroller, M. M. Risberg.

Stewart CUSTOM BILT **NECESSITIES**

"They're More Than Accessories"

You Owe It to Your Business Success to Sell Stewart Products

We do not infer that it is impossible to achieve success without handling Stewart Custombilt Necessities. But we do say emphatically that you are not reaching, and cannot reach, the highest pinnacle of your possible success unless you become known as a headquarters for Stewart Necessities.

You are in business, we presume, for one prime object—to make money. Then you owe it to your business to avail yourself of every opportunity to make money.

In Stewart Necessities you have the biggest and surest money-making opportunity ever offered a dealer. The demand for Stewart Products is already created for you. They are the best-advertised, best-known, best-liked accessories on the market. All you have to do is be prepared to reap the business harvest this year—to fill the tremendous demand.

Stewart Custombilt Necessities are products you can sell with a clear conscience. They are the best values in motordom. They make good every time, or we will.

Install a Stewart "Big Ten" section in your store. Tie up with our wide-spread advertising campaign. Carry all the Stewart Products. It's the only way to get all the profits.

You owe it to your business success to sell the Stewart "Big Ten" Custombilt Necessities. Take a big step forward, to-day, by ordering them from your favorite jobber.

American Report on British Labor Conditions

Findings of the Employers' Industrial Commission of the U. S. Department of Labor

British Government officials and most employers now believe that the best way to arrive at and to maintain agreements with labor lies in strengthening well established systems or organizations of both employers and employees.

There is a marked disposition among workmen to be represented in the national councils by actual workers. They feel that labor union officials have become detached from the atmosphere of the shop and are not in sympathy.

WASHINGTON, D. C., April 21.—The cause of labor unrest in Great Britain today is the demand of the working people for a better industrial day providing not only better wages, but also better conditions of life and labor. This is a brief statement of the basic cause of conditions which are aggravated by the strain of four years of war, the feeling that labor does not receive its proper share of the combined product of capital and labor and the fact that, under the British labor union system, the process of handling grievances is too slow to get adequate and prompt relief.

These conclusions are taken from the report of the Employers' Industrial Commission, appointed by the U. S. Department of Labor to study the labor situation in Great Britain which has just been filed.

The committee found no panacea for industrial unrest. Many of the workmen were found to be critical of and disposed to disregard their unions, believing that the officials of the unions have become detached from the atmosphere of the shops and have thus lost their proper sympathy for the workmen. They also believe that they are not benefiting properly from inventions and improved shop methods.

Inquiries among a large number of workers in many different lines for suggestions for the improvement of conditions resulted principally in demands for employment insurance, health insurance and old age insurance.

It was found by the committee and pointed out in its report that the term labor, which is employed somewhat differently in England, whether used by working men or employers, always carries a recognition of mental as well as of physical labor. Capital is used to define the stockholder who is usually an absentee proprietor, while the term "worker" included every one contributing to the actual management of the business from the managing director to the men who sweep the floors.

Shorter hours of labor form an important factor, and the 44-hr. and 47-hr. weeks, and even 40-hr. weeks, are being demanded.

That housing is playing an important part in the matter of labor unrest was evidenced by the discovery that less than 200,000 workers out of 14,000,000 own their own homes. At the same time

it was found that many workers do not desire homes in England, in contrast to the ambitions of American workmen.

It was found that shop committees, although sometimes difficult to deal with, result in good by bringing about direct contact of employers with employees. The problem appears to be not only that of securing and keeping good shop committees, but also maintaining them under control of large labor organizations. It was because of this problem that the Whitely plan providing the industrial district councils and works committees was formulated.

Beneath the general turmoil and numerous reports of chaos, the commission found no signs of disorder in England and discovered that in general the government, the employers and the conservative employees are agreed; that co-operation between labor and capital is desirable; that conciliation will benefit both the employers and employees in stabilizing business and in preserving regularly organized unions, and that collective bargaining benefits both employers and employees.

Disregarding the radical groups, who, it is thought, are being fostered by foreign Bolshevists, the commission found that the employers are recognizing organization of employees, that both now recognize the need of maintaining production and have discarded the ideas about restricted outputs, and are very much in favor of the Whitely industrial plan. This plan proposes the establishment of industrial councils comprising employers and employees to deal with industrial problems affecting the entire country, district councils to deal with matters of local concern, and works committees made up of workers and the management in each plant to deal with the problems affecting each particular shop.

The commission learned from authorities in England that the radical leaders are opposed to collective bargaining and aim to bring about complete revolution of the present system of society.

Women in industry should not receive the same wages as men, according to the general belief of the British working men, unless they deliver equal value as the men. They point to the fact that unless women produce equal value they will be crowded out of employment if they insist on equal wages.

Following is the complete report of the Industrial Commission, which was composed of E. D. Gundlach, chairman; R. J. Caldwell, Dorre E. Felt, William H. Ingersoll, R. R. Otis and Elden B. Keith, who died while abroad:

Report of the Employers' Industrial Commission

To Hon. ROGER W. BABSON, Director General Information and Education Service, United States Department of Labor, Washington, D. C.:

The commission of employers designated to visit Europe and to report on industrial conditions in order that employers and employees might have the benefit of the longer experience of European—and especially British—employers and labor leaders, submits the following as a statement of its observations in Great Britain:

A Revelation for American Business Men.—What we have learned as to the attitude of the Government toward organizations of labor and organizations of manufacturers and as to the attitude of employers toward the trade unions, and that of labor toward federations of employers, as well as the general system being evolved to handle industrial disputes, proved in more than one respect a revelation to us. We believe it will be a revelation also to those at home, disclosing the promise, we think, of constructive co-operative relations which must result in good for all.

Underneath the seething unrest, as expressed in speeches and in newspapers, we found a remarkable harmony of purpose between Government officials, conservative employees, and practically all employers. These groups are to-day nearly a unit in urging:

First—The spirit of co-operation by recognizing and encouraging organizations of employers and employees; and

Second—The need of maintaining production, former ideas of restrictions on output having been discarded.[1]

The leaders of British industry (the men who control a large share of the world's steel and cotton and other products) and the officials of the great associations of British employers expressed their common verdict as summarized below.

If our observations and findings cause any surprise, our answer can only be that if other American business men will themselves go to Great Britain they will confirm our statements as to the viewpoint of Britain's conservative employers.

Sources of Information

Arriving in London Feb. 4 we presented our credentials to the United States Ambassador. He apprised the British home office, from which we received carte blanche to gather information from any source that seemed to us desirable.

Our next official step was to present ourselves before Sir Robert S. Horne, Minister of Labor, and Sir David J. Shackleton, K. C. B., permanent secretary of the Ministry of Labor.

Both of these gentlemen expressed themselves without reserve. They reviewed the situation in a thoroughly comprehensive manner. This was particularly enlightening, because of the fact that the Ministry of Labor, since its foundation in December, 1916, has successfully devoted a large part of its efforts to adjusting labor disputes and their avoidance.

[1]*All this is predicated on the accepted belief that labor is entitled to more consideration than it has heretofore been accorded.*—THE CHAIRMAN.

Shortly thereafter we were privileged to have an audience lasting several hours with George H. Roberts, at present Food Commissioner and former Minister of Labor prior to Sir Robert S. Horne's appointment a few months ago.

In the meantime, and up to the present, it has been our good fortune to have a continuous series of conferences throughout the day and each evening with members of both Houses of Parliament, the Federation of British Industries, the chairman of the Engineering and National Employers' Federations, and prominent students of industrial problems.

Also on a trip to industrial centers of the north, viz., Birmingham, Sheffield, Manchester and Glasgow, your commission interviewed numerous large employers and officials of labor organizations, groups of workingmen of all degrees of radical and conservative thought. Like the Government officials in London, these employers, the workmen and labor leaders, freely expressed to us their ideas respecting the industrial situation in Great Britain.

We also had the advantage of a conference with the admiral commander in chief of the Rosyth Government Dockyard; also with the chiefs of the municipal tramways, gas works and electric undertakings of the city of Manchester, at a meeting presided over by the lord mayor of that municipality; also with the chiefs of similar municipal services at Glasgow, presided over by the lord provost.

Our search for sources of reliable information and our contact with men rep-

resenting all elements in society, stations in the community, and viewpoints, has been greatly facilitated by the capable efforts of the staff of experts and secretaries who accompanied us.

Summary of the Situation

Here is our summary of the British industrial situation:

In 1914 the leaders of the national labor unions signed an agreement with the Government pledging their organizations not to strike during the war.

But the Government soon found that the existing organizations could not control the workers. Because the hands of the national unions were tied, a succession of unauthorized strikes broke out locally in growing numbers.

Unrest in Individual Shops.—The men in the shops, sometimes through newly elected committees—more often through their regular shop stewards (the name previously given to the representatives of the unions working in the shops)—made successive demands upon their individual employers, either by strike or threat of strike. When an employer gave in to such demands this fomented other demands elsewhere by workers who wanted what others had secured, or more. Against these so-called "unconstitutional" strikes ("unconstitutional" because not authorized by the regularly constituted unions) the national leaders of labor unions seemed well nigh powerless.

The month of the armistice saw the expansion, perhaps more than a beginning, of new forms of organizations of shop stewards among themselves. These men to a large degree, while union men themselves, to-day ignore or defy the orders of the union leaders. By securing concessions from individual employers without regard to the central unions, the shop stewards feel that they have proven their power (temporarily, at least) to the workingmen in the shops.

Radicals Among the Shop Stewards.—Among the shop stewards are the young men of radical temperament and with extremely brief and limited experience in responsibility. They are the ones who are propounding the theories about a new state of society, and among them are the radicals who would eliminate the profit system.[1]

Many of these radical leaders frankly state that they oppose all machinery to bring employers and employees together by collective bargaining, because bargaining and conciliation tend to continue the present system of society.

Opposed to the radical wing of the shop steward movement we find:

First—Employers who are practically a unit in their general attitude;

Second — Regular organizations of labor unions with their leaders; and

Third—Those shop committees that believe in getting together with the employer, not in order to crowd demands until all profits are absorbed by labor, but sincerely and genuinely in order to adjust differences by collective bargaining.

The employers and conservative labor leaders in Great Britain have as their background a prolonged experience in

[1]*It is also to be recognized that among the shop stewards are capable leaders who believe that the demands of the national labor leaders are too modest.*—WILLIAM H. INGERSOLL.

THE COMMISSION'S FINDINGS

1. *EMPLOYERS IN GREAT BRITAIN generally recognize the desirability of bargaining collectively with labor.*

2. *EMPLOYERS nearly all agree that collective bargaining should always be undertaken between associations of employers and the regularly established well-organized trade-unions.*

> *While many manufacturers welcome organizations of workmen in their factories (shop or works committees), they want to limit the activities of such bodies to purely local grievances, and decidedly desire that the committee members come under the discipline of their unions.*

3. *MOST EMPLOYERS freely recognize the right of labor to organize; they regard organization as greatly contributing to the stability of industry. Some large manufacturers declare that they wish to see every workman within the unions, so that they must all come under organization control. Others feel that 100 per cent organization might lead to dangerous types of universal strikes and lockouts. The more conservative employers appear to make no effort to help along organizations of labor, merely dealing with such organizations when they appear on the scene.*

4. *EMPLOYEES IN GREAT BRITAIN are divided in sentiment shading from those who want to maintain the trade-unions along the regularly established so-called "constitutional" lines to ultra-radical socialists.*

5. *EMPLOYEES are nearly a unit, however, in expressing opposition to the use of force. The most radical who desire "now" a complete overturning of the present social structure, usually admit on close questioning that "now" may mean many years. They want to "start" now. Practically none appear to approve of a sudden change as in Russia.*

6. *EMPLOYEES of the ultraradical type look askance at collective bargaining and organizations of labor and capital. They freely express the view that they do not wish harmony between employees and employers, since harmony would help to continue the present system of society.*

7. *EMPLOYEES of the more conservative type (and to your commissioners they appear to represent the vast majority of British workmen) are largely in accord with employers in the desire (1) to head off labor unrest at this period; (2) to strengthen the unions by holding members under control; (3) to increase production for the sake of the nation, workmen included—with no restriction on output except as it affects the health of the worker; (4) to leave control of business policies in the hands of those managing the business.*

8. *GOVERNMENT OFFICIALS appear to be uniformly of the opinion that the Government should function in labor unrest only as an absolutely last unavoidable resort. On the other hand, they maintain the right of the Government to step in when necessary in order to protect public interests against minorities which try to force their terms upon the people.*

9. *IN GENERAL the Government, and most employers and conservative employees appear to be agreed:*

That the spirit of co-operation between labor and capital is highly desirable.

That the spirit of conciliation is important for the benefit of the employer in stabilizing his business and for the benefit of the employee in preserving his regularly organized unions.

That in collective bargaining the right-minded employer will not attempt to return to the pre-war industrial era, and that the right-minded employee will not attempt to crowd his demands to the point at which the stimulus for private business enterprise would disappear.

The spirit of a genuinely better NEW (and not NOVEL) era is thus being fostered by widely varied elements of Great Britain's industrial system.—R. J. Caldwell, Dorr E. Felt, Wm. H. Ingersoll, Robt. R. Otis, and E. T. Gundlach, Chairman.

The more intelligent workers realize that merely advancing wages does not meet requirements if the purchasing power of money is thereby proportionately reduced.

In their demand for a better industrial day, the working people seek not merely small non-essentials, nor commonplace essentials, but a real step forward in their conditions of life and labor.

dealing with each other by organization, and a great majority of them believe that it is best for both employers and employed to treat with each other collectively.

Employers Prefer to See Labor Well Organized—Years before the outbreak of the war the thought of breaking up labor organizations had been practically given up by employers, and the union leaders had abandoned opposition to associations of employers.

As the war measures took away the power of the central organizations over the workmen, the situation which developed seems to have convinced most employers as never before that workingmen are best dealt with by negotiation through large bodies of labor; not necessarily in order to concede to their demands but merely for the purpose of dealing with labor en masse.

For the war showed that irrespective of laws, employers' opposition, or Governmental agreements, workingmen today will find some way or other to act together in groups when their interests are vitally affected.

So the Government officials and most employers now express the belief that the best way to arrive at and to maintain agreements with labor lies in strengthening well-established systems or organizations of both employers and employees. These, they say, can be held responsible and kept to concerted action better than incoherent small groups.

Another point: The shop committees, although often difficult to deal with, proved to many employers that much good resulted from direct contact with their men.

By means of these committees industry avoided the necessity of depending on the detailed and intricate machinery of trade unionism for the adjustment of purely local grievances.

The problem then remained as to how to get and keep shop committees and yet maintain them under the control of the larger labor organizations. An effort in the direction of fitting shop and works committees into larger and more responsible organizations of labor was made by a Government plan, which in the last six or eight months has formed the basis of a great deal of public discussion in Great Britain. We refer to the program set forth in the British documents known as the Whitley reports.

Whitley Plan Explained

Before we came to England our attention was directed to the Whitley reports.[1] They were drafted by a sub-committee of the Committee on Reconstruction appointed by the Prime Minister in 1916.

Briefly the Whitley plan proposes the establishment for each industry of:

1. Joint standing industrial councils made up of representatives of employers and employees to deal with the larger questions that affect the industry throughout the whole country;
2. District councils constituted in like manner to deal with matters of local concern; and
3. Works committees also composed of representatives of the workers in each plant and the management to deal with conditions affecting each shop but not touching the larger aspects handled by the district councils or the national joint standing industrial council. Such matters as shop sanitation, the hours of beginning and ending work, luncheon time and rest periods, are to be dealt with by the works committee.

The Whitley plan is exceedingly elastic. It is not the intention of the British Government to force any cut-and-dried formula upon the industries of the country, but national joint standing industrial councils and district councils are essential to a fully developed Whitley scheme.

Councils in 30 *Industries.*—National joint industrial councils have been formed in 30 different industries, but the fully developed scheme, including district councils and works committees, has been established in only three industries, viz.: Matches, pottery and rubber.

In several other industries works committees have been set up in many establishments in accordance with the recommendations of the Whitley committee. Eventually, these works committees are to be organized by districts and nationally into a true Whitley scheme, but at present they are nothing more than the beginning of such a scheme.

In fact, we soon discovered that the details of the system, which was elaborated in five successive reports by the Whitley committee, as far as being put into operation is concerned now stands in the embryonic stage, and the new machinery has not yet been developed far enough to afford sufficient experience on which to base definite conclusions.

The Whitley plan is viewed with much favor by officials of the Ministry of Labor, which is endeavoring to effect the organization of various lines of industry under this plan.

Various municipally operated public service departments are also proposing to organize under systems based on the general idea of the Whitley plan.

Employers Favor Whitley Plan.—Inquiry developed that the employers, when conversant with the Whitley plan, almost universally favor it; also that employers favor complete union organization of the employed in established labor unions and favor not only collective bargaining, but closer touch with the employed. About the only note of doubt respecting the benefits of the Whitley system, on the part of the employers, relates to the question of the possibility that it might later on lead to undesirable results.

In short, the advocates of the Whitley plan expressed the belief that it would result in complete unionization of all the workers in those industries adopting it; also that it would prevent many strikes. The idea is that small grievances would be adjusted around a council table rather than being allowed to continue as foci of discontent until they grow into grave matters.

Objections of Some Employees.—On the other hand, while some of the higher labor union officials favor the Whitley plan, a large portion of the more radical among the minor labor union officials and the workmen do not indorse it enthusiastically.

Their objection seems to be based, first, on the impression that it would take the place of the regular established labor organizations; and, second, a distaste for Government participation in negotiations and settlements between employer and employed, which the Whitley plan contemplates in certain situations.

Some of the strong and thoroughly organized labor unions, such as the Coal Miners' Union and the Amalgamated Society of Engineers (metal trades), take the position that the machinery of the old established organization and the usual arrangements with the employers afford sufficient means of adjustment of grievances.

Old Established Systems.—In respect to a considerable number of industries both employers and employed explained that they had introduced the equivalent of the Whitley plan years ago. But it usually developed that their arrangements for conference and adjustment of differences between employer and employed did not include the district councils of the Whitley plan, and only in some industries regularly established joint industrial councils. Many of these individual mutual conference arrangements have been very effective in preventing industrial conflict. Some of them have been in operation for many years.

Fortunately, as some declare, England has been experimenting with methods for the betterment of relations between employer and worker so that opportunity has been afforded to witness results over a period of more than a generation. As

[1] *The first (interim) report of the Committee on Relations between Employers and Employed (the so-called Whitley Committee) was made on March* 8, 1917, *and is contained in Bulletin* 237 *of the United States Bureau of Labor Statistics, Washington, D. C. Subsequent reports and the memoranda by this committee are contained in the Monthly Labor Review of the same bureau for May, June, August, September and December*, 1918.

Labor leaders in the Government and leaders among workingmen outside official circles are coming out emphatically against theories of restriction of output.

Most British workers believe they do not benefit in a fair measure in the advantages which inventions and improved methods should provide to all members of society.

confidence was gained by experience, more rapid progress in later years was accomplished. The plan simply carries out and defines more accurately old-established machinery for the adjustment of labor disputes.[1]

The Whitley system was examined with special interest and care by your commission, because this plan is now being furthered by the British Government in the attempts to encourage the get-together spirit of employers and of conservative employees.

Period of Great Labor Unrest

In our interviews we were constantly met with the statement that we had arrived at a time of great labor unrest, and our investigations confirmed this view.

Interviews with many of the workmen tended to indicate that "unrest" is a rather inadequate term. There are many intimations of "direct action" and a complete overturning of the present social structure. But we believe the more extreme demands are largely limited to a class which has been thinking and talking along these lines for years.

The issue, however, is squarely drawn on the demand of the working people to have a better industrial day. They seek not merely small non-essentials, nor commonplace essentials, but a real step forward in their conditions of life and labor.

The relationship in Great Britain between employer and worker is clearly in a state of marked transition. This fact is recognized and accepted by all the country. This process was in its inception before the war and has been renewed with double intensity since the armistice.[2]

We Cannot Report That We Have Found Any Panacea for Industrial Unrest.—For instance, the specially generous treatment of employees, which is possible in connection with exceptional types of highly profitable enterprises, might be impossible in the case of industries engaged in closely competitive operations.

While we do not mean to infer that competition in any industry could be accepted as a reason for denying those engaged in it a reasonable standard of comfort, we did note that some employers, bounded by the horizon of their own experience, seemed to believe that they had discovered or invented methods and practices which will eliminate all industrial conflicts. Their special schemes may be perhaps successfully used under the special conditions of certain plants.

But in this report we are concerned only with principles that may be generally applied for the good of industrial workers, and of industry as a whole.

Causes of the Unrest

The present unrest among the workers is ascribed by different authorities to many separate causes—that most frequently mentioned as the *immediate* cause is the strain of four terrible years of exhausting war, necessitating the most intense labor and excessively long hours for the worker.[3]

Among other alleged causes is a feeling that the worker does not receive his proper share of the combined product of capital and labor. This is universally voiced by the workmen whom we have interviewed.

Workmen Criticize Their Unions—The present condition is partly due also to the fact that grievances through the unions must pass through a rather complicated series of steps, and this procedure, therefore, does not result in prompt adjustment. Ofttimes the conditions contributing to the grievances have disappeared before the decision is consummated.

On the other hand, the shop stewards and committeemen, being in direct contact with the employer, usually succeed in promptly establishing accord between the parties concerned.

There seems to be a marked disposition among the "rank and file" of workers to criticize the present union system because it denies the workmen in the shop an opportunity promptly to rectify grievances, irrespective of their particular craft union. The object of the shop steward or shop committee movement appears to be to rectify this by constituting a shop organization capable of dealing with common grievances.

At the present moment there is rather a widespread feeling among the workingmen that the officials of the labor unions have become detached from the atmosphere of the shop and not in proper sympathy with the workmen. There is a marked disposition among the workmen to be represented in the national councils by actual workers.

The primary organization of unions has heretofore dealt with questions such as wages and hours of labor, which are common to the entire territory, while the shop committees or shop stewards deal with matters peculiar to their own establishments. Sometimes the members of the committee or the shop stewards are those among the men prone to be agitators.

Nevertheless the system seemed to work very well until now, when the men, under the leadership of the stewards and committeemen, are inclined to break away from the leadership and advice of the regular union officials. This condition has resulted in serious strikes and promises of others of still more serious moment to the general community.

All parties seem to agree that the present unrest, often resulting in grave discomfort to the community as a whole, is possible in certain circles only because energetic minorities are able to lead apathetic majorities of workingmen.[4]

Views Expressed by Workmen

Your commission, as stated above, devoted a number of evenings to discussions with different types of workingmen, getting expressions of many widely varied shades of opinion.

One cannot listen to their grievances and hear the stories of their troubles, as voiced by the more intelligent workmen, who are of a very superior type, without being impressed with their sincerity. Periods of unemployment frequently place them in debt, from which it requires years of strenuous effort and self-denial to recover. Many find themselves unable to obtain employment during their later years, after a life-time of constant industry; their wages afford slight means for recreation.

Most of the British workmen believe they do not benefit in a fair measure in the advantages which invention and improved methods should provide to all members of modern society.

The radicals contend that society as now constituted under the competitive system includes many wealthy idlers and a vast system of middlemen which stand between the producer, who is also in a large measure the consumer, and a just

[1] *At a large cotton mill in Lancashire it was stated that for years all differences in the industry had been successfully settled by joint committees, averaging 600 cases per annum. In another industry, no difference had arisen in five years which had not readily been settled without a strike. Another large concern told of 149 out of 150 cases being adjusted without a strike. In not a single instance did I receive an adverse report from either side in any plant where the plan had had reasonable time to become established.*—R. J. CALDWELL.

[2] *The workers, it was found, were greatly dissatisfied with wages, working hours, and housing conditions before the war. But after Aug. 1, 1914, the labor troubles were overshadowed by the greater crisis. Even during the war the workers continued agitation for better conditions. Now that military peace has come the industrial conflict threatens anew with increased vigor.*—R. R. OTIS.

[3] *The strain of the war is an incidental cause in our judgment. The fundamental cause, we believe, is the struggle for better conditions for workingmen. This fundamental is almost world-wide, and Great Britain appears to us as but the index, or perhaps the guide, of far deeper than nationalistic or temporary forces.*—R. J. CALDWELL and WM. H. INGERSOLL. *Shortage of proper amusements, housing, sanitation, and lack of general welfare work for the hundreds of thousands of demobilized soldiers who have either gone back to the shops or are idle, and continuation of some war restriction depriving the working class of many comforts, such as light, certain kinds of food, etc.—all this, to my mind, has had perhaps a more "immediate" depressing effect than some of the more serious, fundamental causes outlined above.*—R. R. OTIS.

[4] *It should be noted that this comment refers only to "certain circles" of labor.*—THE CHAIRMAN.

Less than 200,000 of the 14,000,000 British workers own their homes.

The average workman thinks quite as much of considerate treatment as he does of wages.

Business men freely declared that danger lay in the tendency to "wait for wages to go down" before going ahead with business.

share of what the workman produces. Many of them believe that all profits should be eliminated and that pure socialism is a cure for all their ills.

But when closely questioned along constructive lines they do not seem to have any workable suggestions of what the proposed new order of things should be.[1] They do not state whether or not it might result in a more just, proportionate distribution of the fruits of the combined operation of capital and labor or if it would result in a greater net income and enjoyment of the good things of life to the worker.

Workmen Now Study Economics.—It is obvious that a great amount of study by the workmen is being devoted to the subject and that a section of the younger workmen are being assiduously educated by certain radical groups along socialistic lines of thought. It develops that in one of the cities visited by us there are 14 classes devoted to the teaching of economics, and that a considerable number of workmen attend the classes regularly in preference to the moving picture houses or other recreations.

The theory that this movement is due to foreign propaganda does not seem to be generally accepted, although some employers voice the idea.

Minimum Standard of Comfort.—The more intelligent workers realize that merely advancing wages does not meet requirements if the purchasing power of money is thereby proportionately reduced. This was exemplified to their satisfaction by the experience of the war. Their final desideratum is a wage that will insure a specified minimum standard of living regardless of fluctuations in the cost of commodities.

The workers frequently mentioned the fear of the poorhouse. Security, they said, must accompany all plans to allay labor unrest.

Insurance and Pension Plans.—When asked what substitutes they had to suggest, the reply from quite a few was:

"Unemployment insurance."
"Health insurance."
"Old-age insurance."

These are the things, they said, which the provident would secure for themselves if their circumstances would permit.

It was apparent that the workman thinks quite as much of considerate treatment as of wages, and almost universally the idea was voiced that he is regarded by his employer merely as a "hand" or a number. He feels entitled to consideration and courtesy and very much desires closer *touch and sympathy on the part of the employer. In fact, this phase of the question was usually emphasized by the workman. The little things count, and their neglect magnifies them.*

Lack of Better Opportunity.—The average employee in Great Britain does not expect to rise above the station in which he was born, although a considerable number do become "masters," usually in a small way. Their expectation of always remaining in the same station results in a disposition to think in terms of class rather than individually and tends more toward organization than in America. It makes the British workman less inclined to individual effort than the American workman.

Short Hours of Labor.—The question of short hours of labor was one of the most prominent in all our discussions. In some of the plants we visited the men worked about 54 hours a week—some work more and some less—but one great and successful engineering works adopted an 8-hour day (48 hours a week) 20 years ago. The men in the engineering trades are now working a 47-hour week. They asked for a 44-hour week, and some, in an attempt to provide, as they thought, promptly for a greater number of workers in order to meet the temporary dilemma of unemployment, are now asking for a 40-hour week.

Perhaps a definition should be given of certain phrases current in labor circles of Great Britain, in order that the views of the workmen may be better understood.

Definition of Voice in Management.—Of special significance is the expression, "voice in management." According to the preponderant view of both employers and employees in Great Britain, this phrase signifies only that workmen or their representatives should be heard in connection with the management of matters intimately affecting the workmen, such as the hour of beginning the day's work, a matter on which the shop committees want to be consulted (not length of hours, which is a question for collective bargaining between the unions and the associations of employers), sanitary conditions, safety matters, etc.

In the mind of the average British workman, the phrase "voice in management" does not, therefore, as at present generally understood in America, extend to matters purely commercial or administrative, nor to such questions of business policy as expanding to new markets, purchase of material, selling prices, additional investment in plant, etc. In other words, this phrase pertains to what we call "shop conditions." It does not extend to what are sometimes termed matters of organization and administration.[2]

Definition of "Capital and Labor."—In the expression, "Capital and Labor," the former term as used in Great Britain includes only the stockholder, who is usually an absentee proprietor, even in a close corporation, visiting the works perhaps once or twice a year, if at all. The term "worker" includes everyone contributing to the actual management or prosecution of the business, from the managing director down through superintendent, salesman, office workers, to the men who sweep the floors; emphasis being placed on the fact that "labor" includes both brain workers and manual workers.

The Problem of Housing

Among other matters having direct bearing on labor unrest, we gave our attention to the question of housing. The British Government appointed last year a royal commission to inquire into industrial unrest, and their report was to the effect that bad and insufficient housing played a large part.

Your commission also finds that Great Britain includes in its claims of having fourteen million workmen a large number of clerical men and women in railroad, telegraph, telephone, hotel, and even active clerical men in industrial plants. Out of this 14,000,000 only a very negligible number own their homes. Labor officials approximated the number at less than 200,000. Government officials questioned were uncertain as to the number of laboring men who want to buy homes, while leading realty agents advise it was so insignificant they did not even equip their offices to handle this class of investor.

Reasons for Housing Situation.—They gave numerous reasons for this situation, but the leading ones seemed to be: First, the vested title to land; second, long ground-rent leases, and third, the construction of rows of tenement houses which contained no permanent dividing walls.

Any of these causes would preclude the possibility of conveying to the workman who desires a home an absolute, permanent (fee simple) title to both land and to building.

Other reasons put forward were that the laboring class seldom appeared to have any surplus for home investment, while others did not desire to become identified with any given location, or, expressed differently, tied to any one industrial establishment by virtue of owning a home.

In contrast, it is pointed out that

[1] *It is a matter of opinion as to whether their plan is workable or not. I do not believe it is, but they do; and they are not without a comprehensive scheme of social and industrial organization.*—William H. Ingersoll. *The writer of the text in the report refers to our talks with many men who work at the bench. It is assumed that no one denies that some of the leaders have clearly defined plans.*—The Chairman.

[2] *The above states the idea as commonly expressed to us by many workers. In the language of other workmen, "voice in management" means actual share in the conduct of business. The term has an indefinite variety of meanings.*—The Chairman.

American workmen and clerical men not only desire to own a home but that large numbers of them make every effort in that direction.

Well-posted Englishmen of affairs tell us that in new countries like Canada, Australia, etc., there is a condition similar to that in the United States.

Need of 300,000 Homes.—The British Government now figures the urgent need of from three to four hundred thousand houses for laboring men, and this development is supposed to get under way at once. Yet, under the various housing acts in effect since 1890 the actual construction is as follows: 1911, 464 houses; 1912, 1021 houses; 1913, 1880 houses; 1914, 3335 houses; 1915, 4408 houses.

Also, under these acts individually owned houses of the slum type were made fit by partial condemnation and at the expense of the owners, beginning with 19,463 in 1911 and increased to 67,065 in 1914. Many of these buildings were to take care of war workers.

None of the English housing acts seem to have for their aim the idea of encouraging the workman to own his home, but are almost exclusively rental propositions.

The British Government's present reconstruction measures of underwriting the loss of the present-day cost of building 300,000 houses as opposed to their value seven years hence is a system elaborate enough to warrant special study. But this again does not aim at making the laboring and clerical man or woman a vital part of the community through personal ownership of his home.

No Restriction on Output

A subject constantly discussed in our interviews with Government officials, employers and workingmen was the question of restriction of production and the introduction of labor-saving machinery.

Great emphasis was placed on this topic by the British. The employers naturally plead for high production. Government officials are indorsing this plea; and what is more, the labor leaders in the Government, and also leaders of workingmen outside of official circles, are coming out emphatically against theories of restriction of output.

Again, on this subject, as on others, the radical element stands apart. Some of those who want a fundamental change in society say that under the capitalistic system labor cannot in any event get more than a bare subsistence, and that increased production is simply for the benefit of the capitalists.

"Nation Must Produce to Live."—All others, however, including a large number of those of the "rank and file," so-called, of the workingmen are preaching that the nation must produce in order that the nation may live; and that workmen cannot share in what is not produced.

Practically all labor representatives who believe in continuing the present system of society agree that increased production is in the interest of both employed and employer.

Most of those who favor short hours claim that this is merely for the benefit of the health of the working classes, and arguments are now rife as to whether the total output is decreased or maintained at the same level by a reduction to 48 or 47 hours.

Employer May Be Penalized.—We also found that by agreement between organizations of employers and organizations of workingmen in some highly organized industries, such as the cotton industry, a case may be filed against the employer who, because of bad raw material, is not able to procure a standard output. Such an employer may be penalized by having to pay higher wage rates, so that the workman may make the usual earnings at the prevailing piece-work rates, in spite of poor raw material.

Miscellaneous Topics

Equipment of British Plants.—The various industrial plants inspected indicated that the equipment and organization of the British plants compare favorably with corresponding plants in the United States. It is an interesting circumstance that a very large steel-producing plant in course of construction contained many trains of machinery manufactured in the United States, and the balance of its equipment was built in England under license from and under the supervision of the foremost American designers. Plants developed wholly under British auspices, as a rule, represented a very high state of development.

A Co-operative Organization.—We visited one of the great co-operative commercial organizations which produce and distribute at wholesale and at retail many articles of ordinary consumption. Its turnover amounts to over $60,000,000 annually, and it is not the largest organization of the co-operative type in Great Britain. It operates oil wells, raises tea, manufactures shoes and many other articles. The co-operative feature of this institution pertains mainly to the commercial end of it. Most of the employed are not interested in the institution, although they may purchase a limited amount of stock if they desire. Therefore the labor problems of this co-operative institution, as the managers themselves stated, are similar to those of an ordinary industry.

Holding Back on Non-War Production.—There appears to be in Great Britain hesitation on the part of various enterprises to reconvert to and to go ahead with non-war production. Reasons given are, first, the fear of turmoil in the labor world, and, second, the expectation of lower prices of material and lower wages. It was widely stated that there seemed to be no sound economic basis for the latter expectation.

Business men freely declared that danger lay in the tendency to "wait for wages to go down" before going ahead with business. One of the largest employers in Great Britain, seconded by several others, said that if there was reason to fear serious industrial unrest, it lay largely in this waiting tendency caused by threats of labor disturbances.

Women in Industry.—Women played an important part in industry during the war. There was opposition from workingmen, but this was partly overcome by inviting the female relatives of the workingmen to the plants.

Many people in Great Britain believe that the returning soldier who was replaced by a woman should not now be kept out of his position; hence, hundreds of thousands of women are expecting to go back home or into domestic service.

However, some of the labor leaders themselves, and especially labor men who are now working for the Government, call attention to the fact that equal pay for equal work on the part of women should properly mean equal pay for equal value; that therefore women need not draw the same pay per hour as men; as otherwise women when not capable of delivering equal value would be crowded out of employment.

Improved Conditions of Workingmen.—It seems obvious that during the last hundred years the condition of the workingman in Great Britain has been gradually improving, and that the war will result in acceleration of this process, so that in a few years more progress will be made in a short time than in fifty years of the ordinary course.

Unemployment Insurance.—The unemployment insurance benefit, amounting to 9s. ($2.18) per week for men, and 5s. ($1.21) per week for women, have been superseded for the time being by the temporary out-of-work donations granted by the Government to take care of unemployment growing out of demobilization of the army and of the munition factories. The out-of-work donations amount to 29s. ($7) per week for men, and 25s. ($6.05) per week for women. (The union strike benefit in the engineering trades is about half as much.) In addition to the out-of-work benefits paid by the Government the trade unions pay such benefits, varying from 5s. to 10s. ($1.21 to $2.42) per week.

Minimum Wage.—In Great Britain a minimum wage is established by agreement in the sweated industries, and enforced by the Board of Trade, fines being imposed for violation.

Attitude Toward Ministry of Labor.—It was a matter of some interest to note that while the workingmen seemed to believe that the ministry of labor is pro-capital, the employers seemed to believe that the same department is pro-labor.

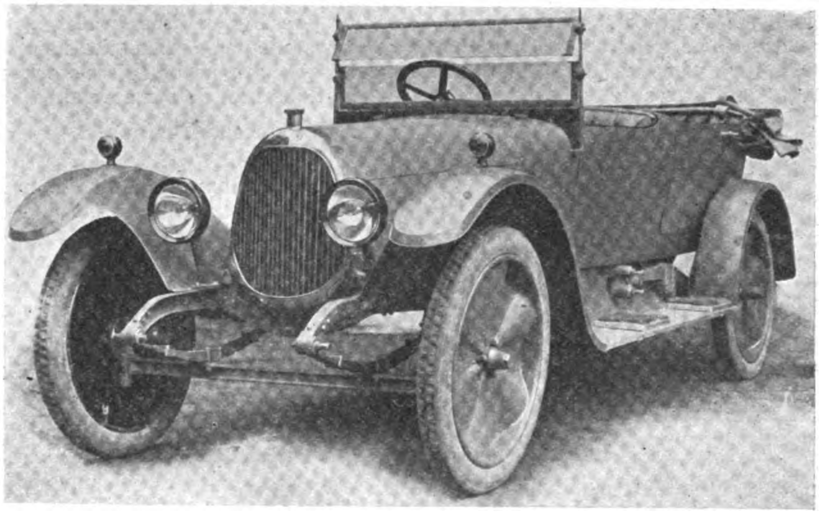
Compulsory Arbitration in Australia.—We were fortunate in meeting on the ship going over Mr. G. S. Beeby, minister of labor for New South Wales, who explained that in his country labor legislation had progressed very far, including compulsory arbitration, special labor courts, unemployment compensation, etc., but that at present the tendency in his country was in the other direction as regards compulsory arbitration, and that it was the general belief that this kind of arbitration had served to intensify labor disputes and increase strikes.

Other Topics Not Covered.—To report even briefly all the matters which came to our notice or indicate all the persons, interviews, and the source from which information was obtained would indefinitely extend this report.

The Angus Sanderson Car

A New British Assembled Product Embodies an Engine with Slipper-Type Piston, Counterbalanced Crankshaft, Integral Cylinder Block and Top Half of Crankcase, and Force-Feed Lubrication—Also a Novel Front-Axle Design

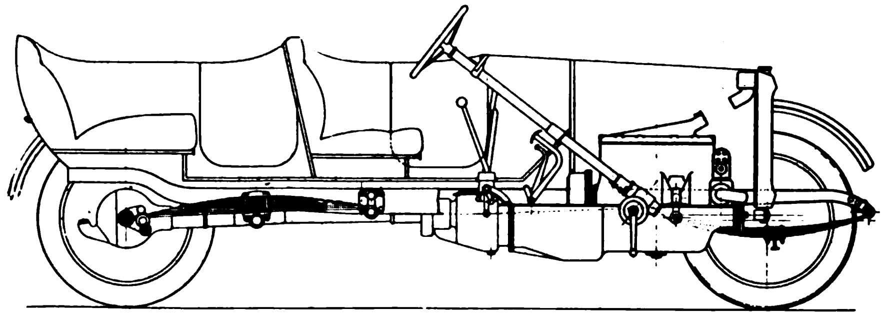
IT is about 10 years since a fair attempt was made in Great Britain to assemble a car from parts made entirely by outside firms, but in which the concern responsible for the car checked up all materials entering into the production of the parts, and in which the limit-gage system of manufacture was used. Such a car was the Weigel, which was virtually a copy of the 40-hp. Itala of that period. That the Weigel car passed off the market was through no fault appertaining to its method of production, for it was an excellent car. After an interval of some years, during which no cars had been assembled from specialized components in Great Britain, a light car produced on these lines is now about to be placed on the market, and it is an interesting coincidence that Frank Woollard, who was the designer of the Weigel car, is also connected with the production of the new car. Mr. Woollard, who during the interval had been associated with the Wrigley Co. of Birmingham, is the apostle of the assembled car in England.



The Angus Sanderson, a new British assembled car

The Angus Sanderson car, to which reference is made in the above, is the product of Sir W. Angus Sanderson & Co., Newcastle-on-Tyne, which has hitherto been engaged in coach building. In the car enterprise the firm has associated with it the Wrigley Co., which will furnish the transmission and the front and back axles; and the Taylor Co. of London, which will supply the engines. Minor components are furnished by other firms. The new car will weigh about 2700 lb., and, equipped with a full roadster body by the Angus Sanderson Co., electric starting and lighting systems, a spare wheel and spare tire, will sell at £450 ($2,250). The wheels are of a new type, with corrugated disk centers, and are said to be considerably lighter than tubular-spoked metal wheels.

Other features of interest in the design are the Ricardo slipper type aluminum alloy piston; the front axle, which is patented by the Wrigley Co., and has T-shaped steering knuckles; also the fact that, with the exception of the central or fulcrum bearing of the rear cantilever springs, all bearings have oil lubrication instead of grease lubrication. The fulcrum bearing referred to is lubricated by means of graphite grease, which is inserted into a hollow pin, which is claimed to hold enough for several months. Interest also attaches to the design of the rear axle, which has a spherical center casing with recessed bolt holes, the object being to obviate all offsets and corners which would tend to retain mud. The differential driving gear can be removed through the back of this housing, and the axle shafts can also be withdrawn without taking the axle down, the latter being of the full-floating type. The lubrication and cleanliness features are of particular importance because the car is specially designed for owner-drivers. It is being fitted with a body which, made before the war under the old-fashioned hand method, would have cost about £150 ($750), and if made now according to the same method would cost about 50 per cent more. The panels are shaped under hydraulic dies, and electric and acetylene welding are being used in joining panels together and for attaching valances and mudguards. The latter are domed and without angled edges.



The chassis of the Angus Sanderson in elevation

An output of 6000 cars is scheduled for the first year, and it is stated that about three-fourths of that number have already been taken up by dealers.

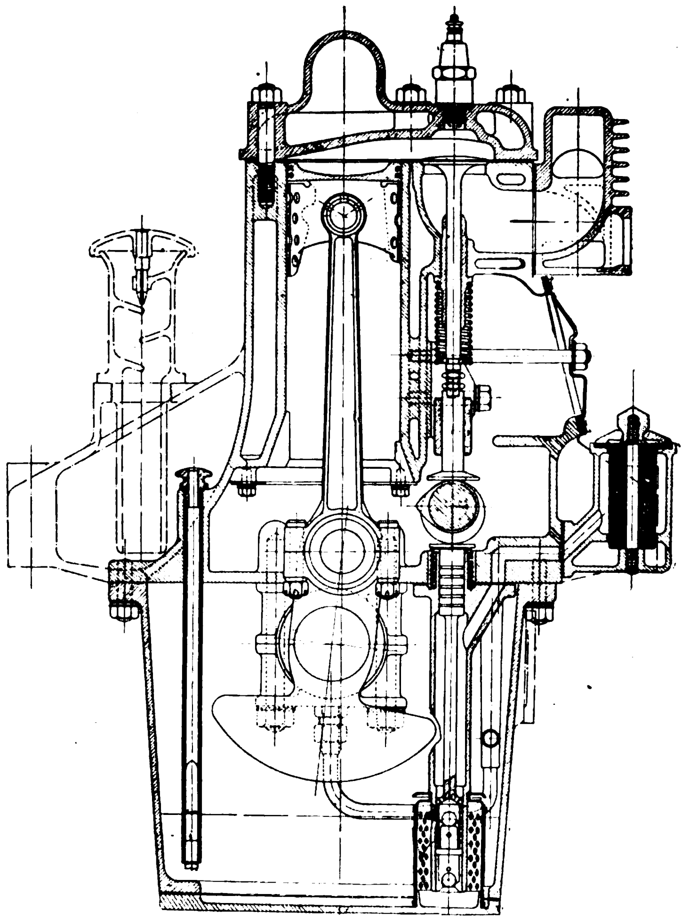
The general design embodies features associated with quantity production practice, but, as the sectional view shows, this is attained without sacrificing stability or a suggestion of the cheap. Details that are new in British car construction include such points as (1) combination of block cylinders with the upper part of the crankcase; (2) careful balancing of the crankshaft by means of counterweights; (3) the sup-

pression of noise (a) by using a specially rigid crankshaft with large journals, and (b) specially cut helical timing gears with cross-gear driven magneto; (4) effective carburetion by a "hot-spot" manifold; (5) specially light pistons of cross-head form (Ricardo's system), with hollow piston pin in a floating bearing, the combination weighing but 12 oz. as compared with 2 lb. for an average cast-iron piston; and (6) the front-axle design and certain details of the rear axle.

The Engine

The four cylinders are block-cast and combined with the upper portion of the engine case. They have a demountable head, valves at the side in common file, and are wholly inclosed by a pressed sheet-metal cover, externally removable tappets with mushroom ends in direct contact with the valve cams. The bore and stroke measure 3 by 5 in. and the S. A. E. rating is about 13.9 hp. Access for removal of the pistons and rods is either through the cylinder top or through the base, which is covered by a large plate. The lower part of the crankcase is of aluminum. The sump has a bottom cover which gives access for the easy removal of the pistons and rods. There are three main bearings for the shaft, with provision for the direct lubrication of each by a plunger oil-pump driven by a cam on the valve shaft. This pump also delivers oil to the timing gears. The latter are of cast iron with helical teeth. The magneto is carried transversely on a bracket and is driven through a flexible coupling by a cross-geared shaft. At the opposite end of the casing is the Lucas dynamo with its armature fore and aft, so that the pulley comes in line with the fan-pulley shaft, both members being driven by a pair of side-by-side pulleys of different diameter on the front end of the engine shaft. The Lucas electric starter is bracketed with the armature fore and aft on the off-side rear corner of the engine, and has pinion engagement for the flywheel periphery, the teeth in which are cut from the solid, the wheel being given an increased diameter for the purpose, corresponding with the width and diameter of the teeth. Both dynamo and starting motor are held in place by a lock-strap across the middle of the cases.

The carbureter is the Zenith, with a horizontal choke-tube and gravity feed from a 7-gal. tank placed under the dash, or, to be exact, fashioned symmetrically so that it forms, so to speak, a continuation of the bonnet curve. The tank has a 3-in. filler cap at both corners, this to facilitate filling and to provide access for cleaning, etc. The water circulation is laid out with the object of insuring ample cooling where most required—about the ignition plugs and the valve throats; also having regard to the reliance on a gravity displacement for its circulation. The radiator is of the vertical tubular form.

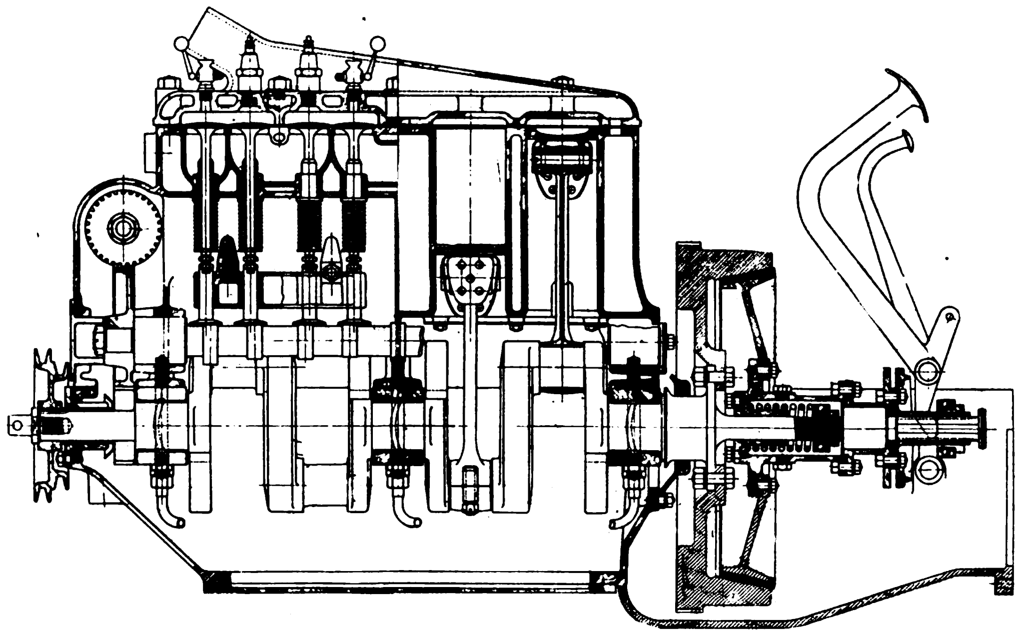


Section of Angus Sanderson engine, showing method of forced lubrication

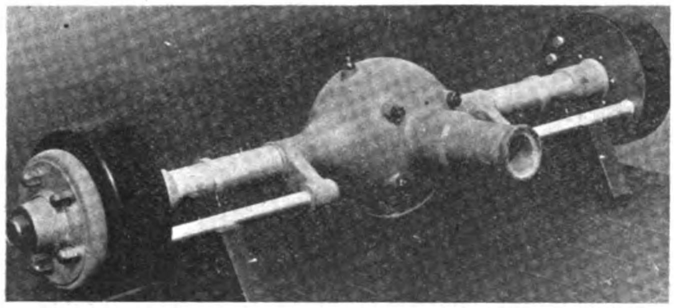
The magneto is of Thomson-Bennett make and has variable timing. Spark and throttle levers are grouped together on the steering post and instead of the conventional toothed sector, a friction lock is used.

Transmission and Drive

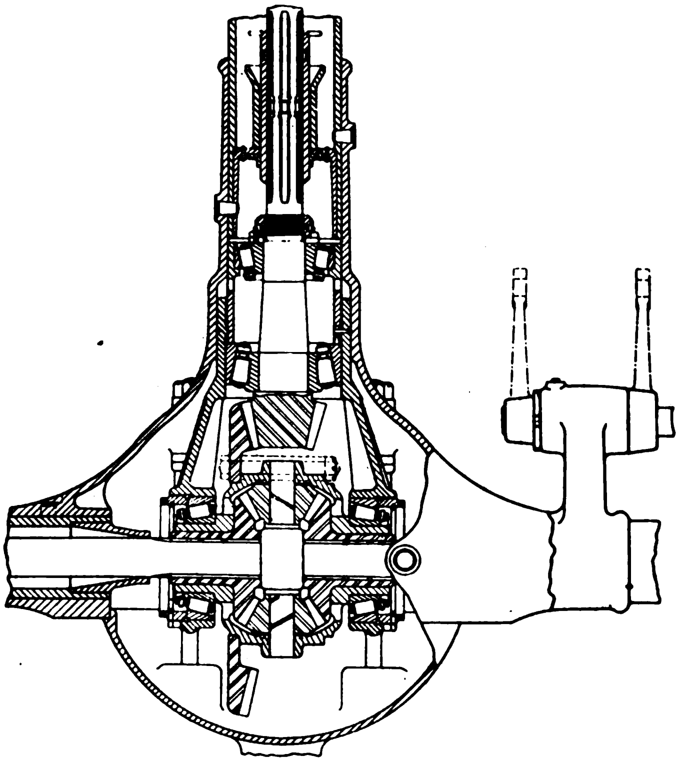
The engine and gearbox are a built-up unit. The clutch is an external cone faced with fabric and made readily demountable by removing some four through-bolts in the clutch members. Clutch rings and arms are one member bolted to a flanged center or boss. The clutch and brake pedals are adjustable. It will be noticed that the clutch spring is inclosed in the



Longitudinal section of Angus Sanderson engine and clutch



Angus Sanderson rear axle with twin side-by-side brakes



Sectional view of the Angus Sanderson rear axle gear housing

flanged casing and that there is a ball thrust behind this spring and another behind the heel of the pedal. There is also a clutch stop or disk brake, and special provision to prevent escape of the lubricating oil from the engine case into the gearcase, and vice versa.

There are three speed gear changes and a reverse, the top speed being the usual direct drive. The primary or sliding gear shaft is carried in ball bearings, except the pilot, which has a floating bronze bushing. The layshaft is carried in bronze bearings and is below the primary shaft. Provision is made to insure the continuous circulation of oil (a thin quality is used throughout this chassis) and to prevent splashing and loss by leakage. The vertical sleeve in which the speed lever works has provision against idle play and clatter and serves as a vent for the heated air. There is provision also in the sliding rods against more than one gear train being meshed simultaneously. The gear ratios are progressive in the order of 4.2 to 1 (top, which is also the back axle gear ratio), 6.8 to 1 (second), 13.8 to 1 (first), and 18.4 to 1 (reverse).

The rear axle unit is a composite of cast steel (center and brake carriers) and wrought sleeves (axle housings). The center casting or axle gear differential box is spherical and devoid of flanges and projections liable to collect mud. Access to this case is from the rear by a cover held with four nuts. By undoing four nuts in the front of the center case the whole of the differential, crown wheel, and bevel pinion, together with the bearings, can be withdrawn from the car case for examination. A micrometer adjustment is provided to the crown wheel and bevel pinion, by which it is possible to obtain an adjustment to within practically one thousandth of an inch. A bevel differential is used, there being two star pinions. A special arrangement exists to prevent the oil leaking from the center case, except in predetermined quantities. It is possible to withdraw the differential shafts by means of a jack nut, which, when rotated, pulls the shaft from the hub shell, the taper on the shaft being reversed to permit of this. The hub shell is held in position by means of the journal bearing and a bush which is free from the hub shell except when the axle shaft is withdrawn. Goodyear detachable wheels of a novel corrugated disk form are used with 815 x 105 mm. Wood-Milne rubber safety tread tires having extra thick treads. The steering wheel has an Exonite-covered rim. The bearings to the swivel pins are widely spaced, and the hubs are carried on rotating stub axles which, it is claimed, practically is equivalent to the semi-floating type of rear axle shaft. Thus it is possible to spread the bearings from twice to two and one-half times the usual amount of spread allowed in the normal type of axle, besides enabling more adequate provision against moisture and grit, and also enables the axle to be lubricated from two points only.

New Rust-Proofing Method

PROF. BARFF in a Swiss engineering journal publishes a method of protecting iron from rusting that is more durable than any yet known. The iron to be treated is exposed at red heat to the action of superheated steam. This gives a surface coating of black iron oxide that is a complete protection against rusting. The protection thus afforded depends on the temperature of the steam and the length of the treatment. The coating is very hard, adheres very firmly and shades off inappreciably into the changed mass of the iron.

If the iron is exposed in a chamber heated to 260 deg. C. for 5 hr. and acted on by superheated steam, a coating is formed that will withstand the action of emery paper for a considerable time. If the temperature is raised to 650 deg. C. and the time of treatment to 6 or 7 hours, the surface coating will resist the action of a file.

Gears for Tractor Construction*

Materials and Dimensions—Importance of Using High Grade Steel on Account of the Resulting Compactness of the Transmission and the Greater Facility of Enclosing It

By E. J. Frost

THAT the tractor has come to stay and is going to be an important factor in the future development of the world, from an industrial and agricultural standpoint, few will dispute. That its manufacture and sale will add tremendously to the wealth and prosperity of those countries capable of producing and marketing it in any considerable quantities, also needs no debate. That the tractor of to-day has in any large measure reached its ultimate development and will satisfy the needs or ideals of the future is very much open to question.

The histories of the passenger car and the truck both point to development covering a period of years, and, judging from the new features brought out each year, the end is not yet. It is therefore unreasonable to suppose that in the short time of experimenting and trying out in actual field service a mechanism will have been developed that will measure up to the requirements of the future.

Fron an engineering standpoint the problem seems to have been approached mainly from two different angles, due to the previous training of what might be called separate schools of engineers. Naturally one of the first to enter this field of endeavor was the man having had training and experience in making agricultural implements, with very little or none in engine, clutch, transmission, differential and radiator design; and it is natural to expect that most of the thinking of this type of engineer would be strongly biased by the previous experience with horse-drawn agricultural implements.

The other type came, naturally, from the passenger car and truck manufacturing interests, and while he might have had all the experience and ability necessary in connection with the power end of the problem, he naturally was lacking in the lore of the implement man.

The Biased Implement Man

It is natural that the implement man should be biased toward the use of cast gears and unprotected internal gears and chain drives, and that to many such strength and ability to resist wear should be represented only by cast-iron, malleable, or possibly steel castings, in most instances large to the point of being cumbersome, and frequently incapable of being properly housed to retain lubrication and keep out dirt.

The subject of upkeep, cost of repairs and accessibility of the parts is going to be given increasing attention by future buyers, and it behooves designers to spend any amount of thought and time necessary to attain the desired ends.

A careful analysis of the physical properties of the cheaper materials sometimes used, as compared with even medium priced alloy steels, will disclose the fact that smaller gears and shafts can be used, giving equal resistance to wear and shock and permitting assembling in much smaller housings, greatly facilitating protection from dirt and making it much easier to apply proper lubrication. I assume, too, that frequently these substitutions can be made with little or no increased expense, due to the decreased size lessening the machine work, and the decreased weight of setting the increase in cost per pound.

In a paper of this character time will not permit of an extended discussion of the varied requirements to cover the entire gamut of tractor design, as in all probability each case would have to be analyzed by itself, taking into account the power, speed, drawbar pull, weight and any other items affecting the required strength; and possibly considerable experimenting and field trials would be necessary to determine proper sizes.

It is apparent even to the casual observer that both extrèmes have been reached, and it is evidently unfair to ask a successful manufacturer of gears to, on the one hand, put his trade mark on and guarantee the durability of another man's design, known to be wrong, because too light, and, on the other hand, compel him to equip his shop with machinery for cutting teeth of a size so large and overpowered as to make it only a question of a season or two before a decided alteration must take place.

Conferences of Engineering Staffs

It would seem, therefore, that the best interests of the tractor manufacturers would be conserved by conferences of their engineering staffs looking, as far as possible, toward standardizing design and materials of construction, in an effort to improve the general average and increase the confidence of prospective buyers.

It also might not be amiss to call for such help as the American Gear Manufacturers' Association can give, and I am sure that I voice the sentiment of those here when I say that we would give nothing short of the best we have.

A carefully made 3½ per cent nickel, low carbon steel suitable for case hardening may safely be used for tooth pressures way in excess of common open-hearth steel, and the same is true of chrome nickel and chrome vanadium; the latter, however, in the hands of those inexperienced in its heat treatment to secure machinability may find considerable difficulty in maintaining uniformly good results, and have to slow down so much in making and cutting the blanks that the work becomes unprofitable.

Higher carbon (40-50) chrome nickel may also be used in many instances, with good results, as such material can be heat treated to give the required physical properties so far as tooth strength is concerned, and when properly made by the mill will give good wearing service, although soft enough so that a new file will bite the teeth.

The only trouble I have found with a steel of this

*Paper read at the American Gear Manufacturers' Convention at Cleveland, April 14-16.

analysis was destruction of the contact surfaces of the teeth due to what is termed "pitting," and the only explanation we could find for our difficulties was that something had gone wrong in its manufacture at the mill.

The chemical analysis showed material up to specifications, and the microscope revealed nothing that we could assume pointed to trouble. However, the trouble existed and in our effort to eliminate the difficulty we experimented with steel of the same analysis, but with the carbon content increased from 0.37 to 0.45.

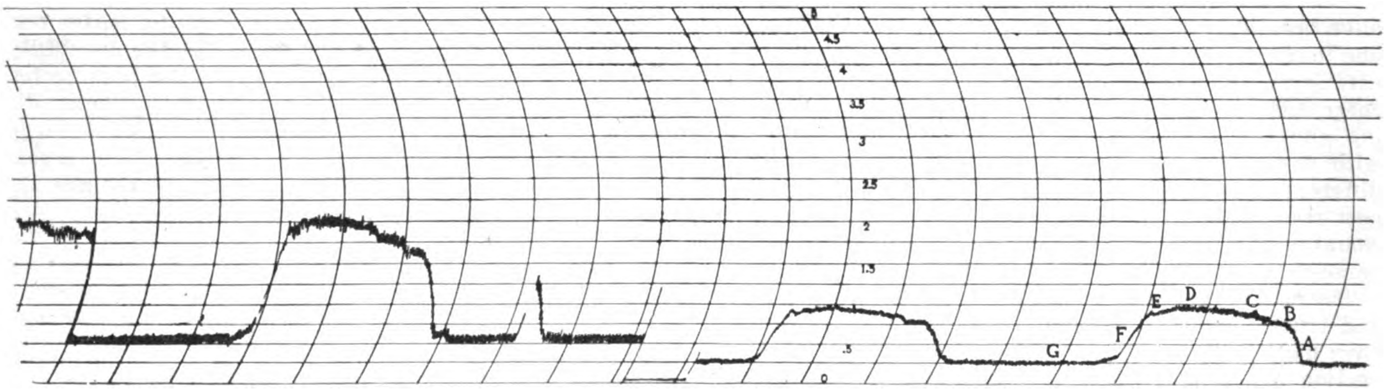
This did not remedy the pitting, and I went so far as to take out a set of gears from an automobile transmission after having been driven 20,000 miles and showing no appreciable wear, and substituting a set made from the chrome-nickel steel of 0.45 per cent carbon, and with the scleroscopic hardness, checked by the Brinell machine, considerably raised, and these failed, showing considerable pitting in 500 miles.

It is therefore evident that where steels are to be used that in service will approach the destructive limits, great care must be taken to see that not only do they check up as to chemical analysis and physical properties as originally determined, but that experiments should be made to satisfy us that the individual batch of steel under consideration will stand up under the proposed load, speed and other conditions.

My criticism of what I saw at the Kansas City tractor show is along two lines: first, there was such a multiplicity of levers, reach rods, valve tappets, links, chain drives and in too many instances gears unprotected from dust and grit, that if an owner spent most of his time wiping up, the tractor never would be clean. Second—and to my mind a serious matter—the bull gears and main drive pinions and frequently other gears, were left unprotected. I imagine this was due to excessive size, which can be corrected only by using better materials of construction which will permit of adequate protection without making the housings too cumbersome.

Electric Graphic Meter for Testing Machine Characteristics

Fox Machine Co. Makes Use of Meter for Testing Finished Machines—Power-Consumption Characteristics of Drill Presses Clearly Brought Out



Sample strip of tape from the Esterline Graphic Meter used in the plant of the Fox Machine Co. for determining power consumption of machine tools. This tape illustrates the characteristics of a multiple spindle machine drilling six ½-in. holes in a 1¼-in. cast-iron plate

An interesting use of the recording wattmeter is made by the Fox Machine Co., Jackson, Mich. The instrument is an Esterline graphic meter and is used for determining the characteristics of finished machines. This company manufactures multiple-spindle drills, milling machines, etc., and it finds graphic records of this kind valuable in determining whether or not the characteristics of the finished machines are as required.

The machine is put on the test stand and the recording meter is connected with it. Then the machine is started, and the power consumed while the machine is doing a typical piece of work is recorded. The record illustrated herewith is from a multiple-spindle drill with six ½-in. drills going through a 1¼-in. cast-iron plate.

In reading the charts, proceed from right to left. Space between the curved lines represents time, and vertical space above the base line represents electric energy in kilowatts.

There are two characteristic curves shown on this sheet, the first being on a scale of one to four and the second on a scale of one to two. That is to say, the records of the curve on the right must be multiplied by 4 to get the correct result in kilowatts, and with the curve on the left the scale readings must be multiplied by 2 to get the consumption.

Both these curves show similar operations. Passing along from right to left it will be seen that as soon as the drills strike the plate the current drawn rises in a practically straight line to a certain value, and then there is a great reduction in the rate of increase. That portion of the curve marked A is where the drill is entering the cast-iron plate.

At point B the drilling operation is well under way, with the full diameter of the drill cutting. It will be noticed that at C on all of these curves there is a slight deviation, which seems to be characteristic of the drilling

Post-War Finance and Our Export Trade

The Effect of the Removal of Governmental Support on Sterling and Franc Exchange—Our Opportunities and Obligations Growing Out of Our Large Foreign Loans

THE American business man is awakening to a realization that the prosperity of the country depends to-day upon increased production. With this realization, and resulting from it, comes also the understanding that we must expand our foreign markets instead of letting them contract. So said Mr. Francis H. Sisson, vice-president of the Guaranty Trust Co. of New York, in an address on our post-war financial problems before the recent Industrial Conference of the New York Business Publishers Association.

In view of this fact, the withdrawal of governmental support from sterling and franc exchange presents one of the most immediate and vital post-war financial problems. It concerns the importer and the manufacturer of domestically consumed products as well as the exporter and manufacturer of goods which are sent abroad, for it establishes an invisible tariff against American goods in England and France, which, sooner or later, but inevitably, said Mr. Sisson, will affect our domestic trade.

Our large foreign loans also present huge problems. Our prosperity, said Mr. Sisson, is now, more than ever, contingent upon the prosperity of other nations. We must understand that our large war-time loans to foreign countries can never be recalled. We have permanently invested abroad. We must also invest a large portion of the interest due on foreign loans in foreign securities. We must help our debtors to rehabilitate themselves; but in doing so we shall be helping ourselves.

There are grave responsibilities in investing in foreign securities, particularly for those who are not experienced at it. Our banks, said Mr. Sisson, realizing that they must assume a large part of this responsibility, are preparing for it by studying the problem carefully and enlarging their facilities for extending service along this line.

But more is needed, Mr. Sisson feels. The banks, and through them the investors, must be supported by the Government. The property rights of its citizens must be protected by the United States. American investors in foreign lands must be assured that, "regardless of the administration in power at Washington, their property rights abroad will be defended, if need be, scrupulously and sternly."

We quote from Mr. Sisson's address:

Despite the heavy financial burdens imposed by the war, America is confronted with an embarrassment of riches—at least so far as indebtedness to this country is concerned. And thoughtful business men throughout the country are beginning to realize that our position as the greatest creditor nation of the world has its serious disadvantages and responsibilities. We gradually are comprehending, also, that whether or not there shall be a formal organization of a League of Nations, we are bound to other peoples by innumerable and far stronger ties than those which any international covenant could impose.

There has, indeed, been no more convincing proof of this fact than that recently provided by the "unpegging" of, or withdrawing of governmental support from, sterling and franc exchange. The larger significance of what was seemingly only a financial operation is daily becoming more apparent. It marks in a dramatic fashion the shifting from a war to a peace basis, not alone in financing, but also in practically every economic phase of international relations. It is one of the most immediate, vital post-war financial problems, and concerns the importer and manufacturer of domestically consumed products as well as the exporter and manufacturer of goods which are sent abroad—for it creates an invisible tariff against American goods in England and France which, sooner or later, but inevitably, will affect our domestic trade. We are awakening to a realization that the prosperity of the country to-day depends upon increased production and, consequently, that it behooves us to expand our foreign markets, instead of letting them contract.

Our Recent Trade Balance

It is true that during January and February of this year the value of our exports has exceeded the value of our imports in record-breaking amounts. The statistics recently issued by the Department of Commerce show that our exports during January exceeded those of any other month in the history of the country, aggregating in value approximately $623,000,000, which was $57,000,000 more than in December, and $118,000,000 in excess of January, 1918. In February of this year our exports were valued at $588,600,000.

These are decidedly encouraging figures, but we must not be misled by a superficial consideration of their significance, and forget what such unprecedented purchasing abroad of our products entails. We cannot continue to ship such enormous quantities of goods overseas unless the buyers pay us for them. There are three ways in which they can settle their bills, namely, by means of goods or service, by gold, or by securities or other instruments of value.

If we are to increase our production, which, as I have pointed out, is necessary to the maintenance of our prosperity, we cannot take goods in full exchange for our products. Besides, we are nearer than any other people to economic independence, and do not need imports in anything like the quantities necessary to settle the trade balance in our favor.

We Do Not Want More Gold

Payment in gold is as impossible as it is undesirable. The value of the excess of our imports over our exports in January alone exceeded the total value of gold produced in all countries, except the United States, during 1918. In addition, we now hold more than one-third of the world's reserve of gold coin and bullion, having added about $1,500,000,000 to our store of the precious metal in the last four years. We could not with safety drain other nations of their remaining low stock of gold, if we would, for as we are already their creditors to the extent of about $12,000,000,000, it is imperative for us to help them maintain their currency on as sound a foundation as is practicable under existing circumstances.

The granting of credits to purchasers of our goods will very materially aid in solving the immediate problem of financing foreign trade, but, at best, it can be only a temporary expedient.

This expedient was necessarily resorted to on a colossal scale during the war, and England was able to weather so successfully the financial storm during the early stages of the conflict and to lend large sums of money to her less fortunate allies because she had extensive credits and investments scattered all over the world.

Before the war England had "invisible exports" amounting to approximately $1,800,000,000 a year, consisting chiefly of interest in foreign investments which totaled about $1,000,000,000. The toll from foreign freight carried in English ships netted her something like $800,000,000. So that while England apparently had an adverse trade balance in 1913 of $670,000,000, in reality she had a favorable balance to the extent of more than $1,100,000,000.

On the other hand, our favorable trade balance of $500,000,000 prior to the war was about equalized by our payment of interest and dividends abroad, freight rates, etc.

Then war came, and Europe, plunged into the most destructive of conflicts, needed in vast quantities the products of our fields, factories and mines. American securities held abroad were sold back to us in wholesale quantities, in order that munitions and supplies might be purchased with the proceeds; more than $2,000,000,000 were lent to foreign governments through private channels in this country, and subsequently, foreign governments floated large loans in our markets.

When we entered the war, the financing of our Allies was naturally taken over by the Government, which advanced credits to them to the extent of more than $9,000,000,000. There remains less than $1,000,000,000 of the fund appropriated by Congress for the purpose to be lent to our Allies.

And it is to meet the situation created by this circumstance that the Government is arranging to aid American export trade by advancing $1,000,000,000 through the War Finance Corporation. Without entering into consideration of the merits of this plan, it will readily be seen that it consists merely of the granting of credits for purchases here and, therefore, can only be in the nature of an expedient, even though the credits extend over a period of five years. Furthermore, if the value of our exports continues to exceed the value of our imports at the present ratio even $1,000,000,000 cannot be effective as a remedy.

While there has been no official statement issued by the British or French Government as to the reasons for withdrawing their support from sterling and franc exchange, respectively, one result is inevitable, namely, the curtailment of the purchase of American goods in France and England. This is probably one of the two principal reasons for the so-called "unpegging" of these exchanges. The other reason was doubtless the high cost of supporting pounds and francs at the figures at which they had been held prior to the withdrawing of Government support.

The Invisible Tariff

Both England and France realize the danger of piling up huge indebtedness for our products on top of the pyramid of such obligations already existing. They are well aware that by permitting exchange to take its natural course, the American dollar must inevitably be at a premium, which means, of course, that less can be purchased in France and England by the dollar than heretofore, and, consequently, buying of American goods will be discouraged. As I have remarked, an "invisible tariff" is thus created against our products. We cannot criticise England or France for taking this protective measure, particularly when we consider that the support of sterling exchange necessitated the purchase by British agents of between $3,000,000,000 and $4,000,000,000 worth of sterling in the American market during the period in which exchange was controlled by the British treasury.

As one English authority recently explained, England "had been bearing the burden of maintaining the relation of sterling to the dollar not only up to the day when the United States came into the war, but ever since. It has been very costly borrowing dollars daily or weekly at 5½ per cent in New York to pay for all the sterling bills offered in London at $4.76 per pound.

"A point often arises in the relation of debtor and creditor when it is the creditor, and not the debtor, who is on the anxious seat," this same authority observed, and he added, "I think that this is the case now in our relation with the United States. At any rate, I am satisfied that it is quite as much the interest of the United States to-day to maintain the relation of dollar to sterling as it is ours to maintain the relation of sterling to dollar, and it is about time to leave the exchange to adjust itself."

It might have been advisable, however, to have cushioned the shock by a gradual readjustment, but that would not have altered the fact that so long as our dollar is at a premium, this country will be a good one to sell in, but a poor one to buy from—which is the vital element not only in the present exchange situation, but also in the whole problem of financing foreign trade.

The Solution

The solution seems to lie, as I have indicated, in the purchase here of foreign securities. We may as well understand now that we can never hope to recall all of our foreign loans, and that, knowingly or otherwise, we have invested abroad on a permanent basis. There is no doubt about our having to invest abroad some of the heavy interest due on foreign loans.

But that should prove to be one of our greatest assets, as it proved to be one of England's when the unparalleled crisis of 1914 shook the foundation of civilization. It means also that we are in world affairs on a scale never dreamed of a few years ago—and we are there to stay. Comprehending that truth, we must take full advantage of it, not only for our own sake, but likewise for that of our debtors. Our prosperity now is more than ever contingent upon the prosperity of other nations. In helping them to rehabilitate themselves we are helping ourselves. And we are amply able to render the needed assistance in the form of foreign investments.

We possess the greatest national resources of any people on earth; our yearly income is greater than that of any other nation, we lead the world in production and commerce; we have the largest total of saving as well as the largest per capita savings—amounting in 1919 to $113.45 a person, and to a grand total of more than $10,800,000,000, which represents an increase of more than $2,225,000,000 since 1914. The amount of "free gold," that is to say of excess reserves, in the Federal Reserve System, which represents the surplus lending power of the system, is sufficient to support a reserve note circulation of more than $1,500,000,000, a significant index to our reserve financial power.

But investment in foreign securities involves grave responsibilities, particularly for the unitiated. Realizing that part of this responsibility will fall upon them, our leading banks, in anticipation of the service which they will soon be called upon to render, are now studying the foreign security problem with a view to affording their customers the largest possible share of protection.

Government Co-operation Imperative

The utmost care must be exercised in determining what foreign securities shall be offered to the American public. We shall have imperative need for expert knowledge of all factors behind these securities. Our banks can be trusted to do their part in this new field, but they cannot perform their functions fully and properly unless they and our investors have the support of our Government.

Aside from the material security which will guarantee the repayment of capital and interest, there is involved the question of property rights. These rights must be protected by the United States Government. It is high time that a policy which would afford such protection be formulated and put into practice—not perfunctorily, but actively and earnestly—so that our investors in foreign lands will be assured that, regardless of the administration in power at

Fordson Tractor Assembly Wholly on Progressive Plan

PART I

Parts Move from One End of Assembly Building to Other Along Moving Chain—Sub-Assemblies Fed from Side

By J. Edward Schipper

PRODUCTION of Fordson tractors is now running at the rate of 300 per day. A new plant, completely surrounding the present one, is being constructed, and as each new unit in the plant is finished it is occupied in accordance with a well-defined plan of expansion.

The entire works may be considered as made up of two departments, production and assembly. Each of these has been added to in turn. After the manufacturing facilities have been increased and the latest in tools and production systems installed, the manufacturing end will push the assembly, causing perhaps an extra shift on that department. At the present time, however, the pendulum has swung the other way, and what will practically be the ultimate assembly system of the plant has just been put in operation.

The new method of assembly incorporates the latest ideas in progressive methods and goes beyond that of the Ford passenger car plant. The system is not yet completely in use, as the new assembling building is hardly a month old; nevertheless the principles are here and their description forms a wonderful story of up-to-date assembly methods as applied to tractor manufacture.

The assembly department occupies a long, rectangular building, approximately 1000 by 190 ft. Down the length of the building pass the chain systems used in assembling the principal units, so that the tractor starts at one end of the building in the form of rough parts and leaves the other end in the form of a finished tractor. There are two principal main assemblies to the Fordson tractor. One of these is the engine, the other the transmission housing. When these two are bolted together on the housing flange at the rear of the engine there is only little left to put on the tractor, outside of the radiator, seats, accessories, etc. This being the case, the assembly system is naturally laid out so that engine assembly and the transmission housing assembly travel along parallel lines until both are complete, whereupon the lines of

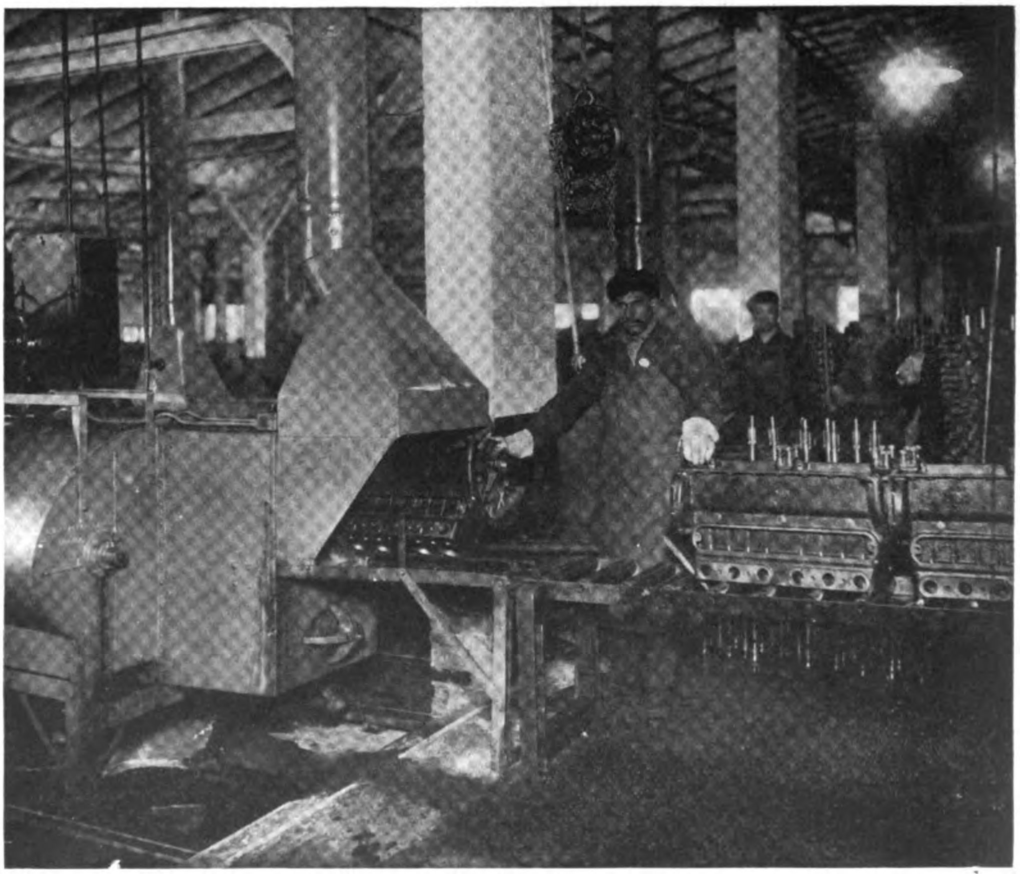

Fig. 1—Cylinder blocks leaving the gravity roller conveyor of the machine shop department and entering the assembly department through the washing machine

Fig. 2—Cylinder blocks leaving washing machine on overhead conveyors to beginning of assembly tracks

through its various steps, we can follow the engine block from the time it enters the assembly building until it reaches completion, and then follow the transmission housings until they reach completion, where we will see how these are joined together to form the finished tractor. The tractors are then run under their own power into the paint shop, painted and sent off on their way. The large general map herewith will show how the assembly department is laid out, and this should be studied to get a general impression of the large rectangular assembly space with its track systems carrying the parts along, step by step, until they are completed.

The cylinder blocks leave the final machine-shop inspection room on the gravity roller conveyor and come directly to the beginning of the assembly line on this same conveyor. They have been completed in every respect and have the main bearings and caps in place. The machine-shop roller conveyor terminates at the beginning of the assembly conveyor and is shown in Fig. 1, where the fin-

travel of the two units converge and they pass along the final portion of the assembly line together until they leave the end of the chain as completed tractors.

Assembly starts as soon as machining of the two large units is completed. There is therefore no necessity for storing such big parts as engine blocks, the large castings which contain the transmission and rear axle parts and the rear axle housings. The latter are large conical-shaped castings which cannot be stored conveniently.

The assembly department adjoins the machining department, so that the machine-shop conveyors which have passed the raw material along as it goes through each succeeding machining operation to the final inspection leave the final inspection department and directly enter the assembling department. The two long lines of assembly become apparent immediately at the entrance to the assembly building. One line takes the engine blocks; the other line takes the transmission housings.

Tracing the assembly

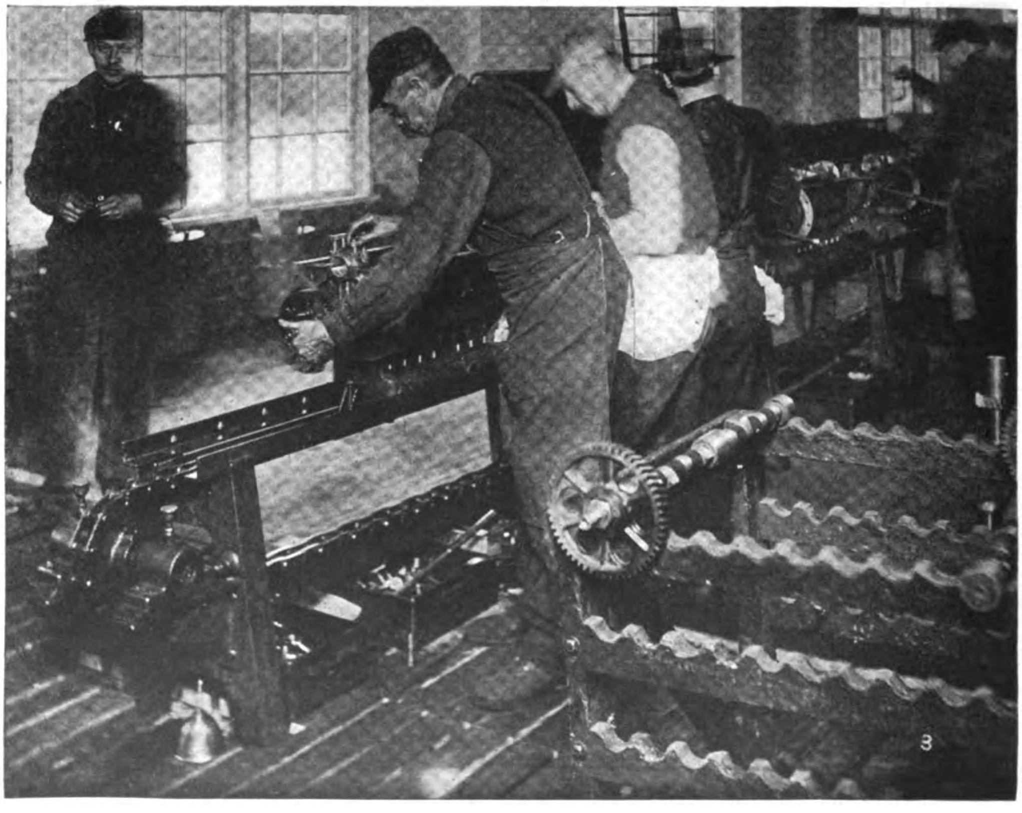

Fig. 3—The first step on the assembly chain is to fit the cam and crankshaft, meshing the timing gears properly. Note the rack for camshafts just behind the operator

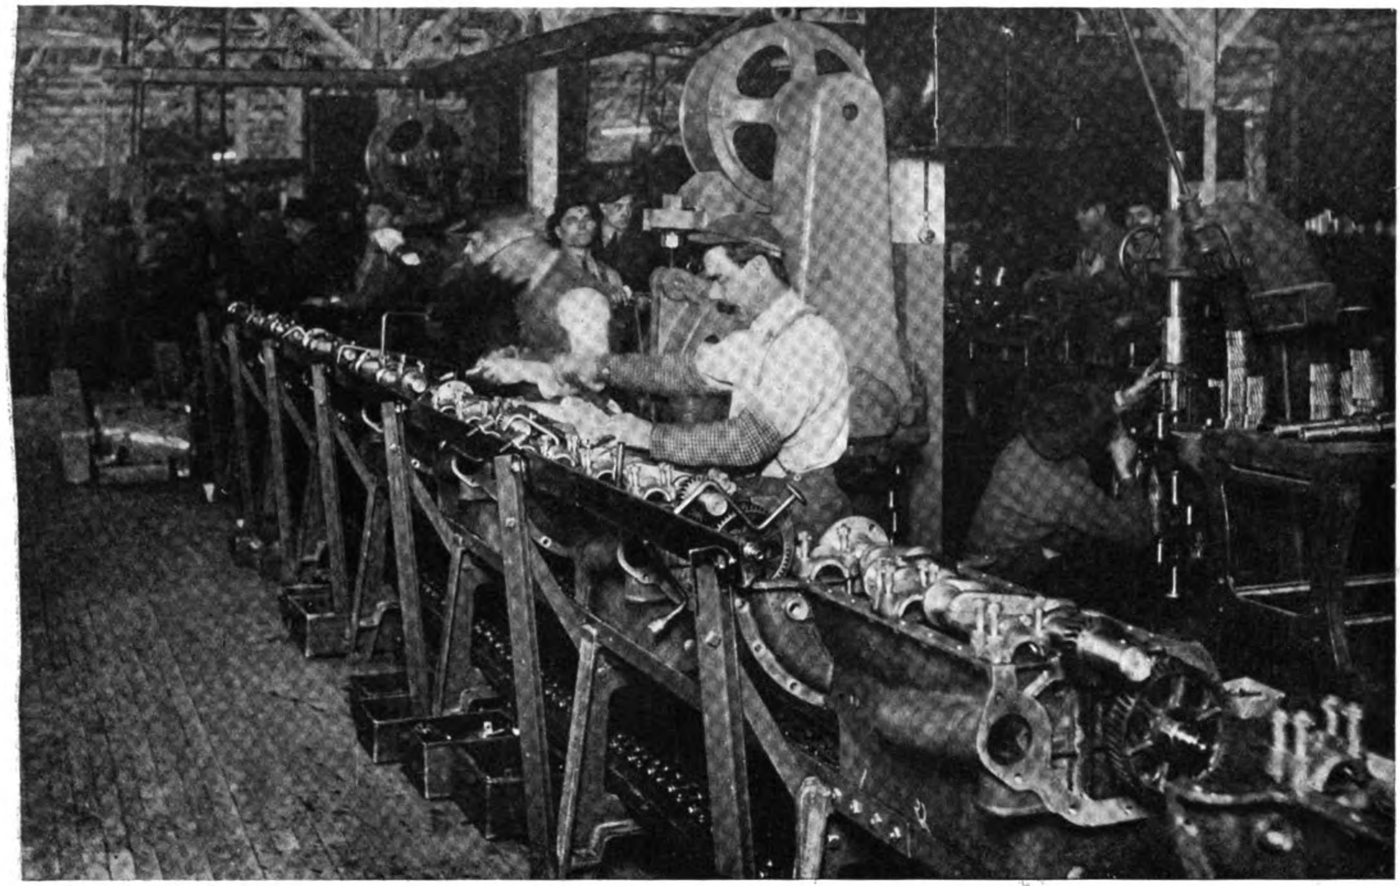

Fig. 4—First section of cylinder block assembly chain, where bearings are adjusted

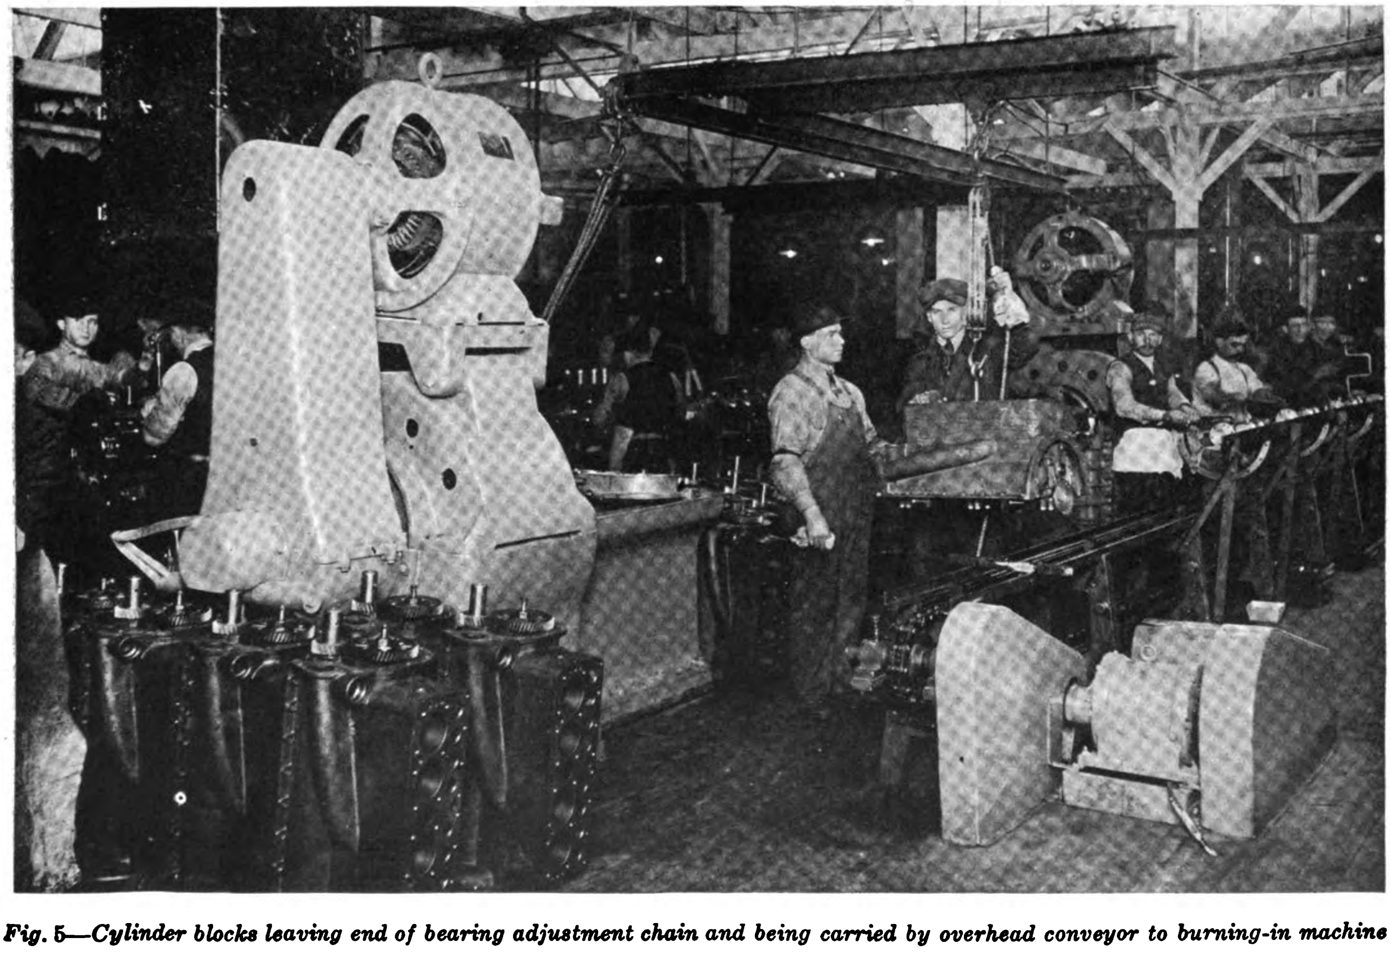

Fig. 5—Cylinder blocks leaving end of bearing adjustment chain and being carried by overhead conveyor to burning-in machine

ished blocks may be seen coming down the gravity conveyor and entering the assembly building at the start of the assembly conveying system. The assembly building is defined in Fig. 1 by the large brick pillars which divide it from the machine shop.

Immediately the blocks enter the first of the assembly lines they are passed through a large washing machine, electrically driven, in which they are washed in a strong boiling alkaline solution. The washing machine, which is partly shown in Fig. 2, is a product of G. S. Blackesley of Chicago, and is capable of handling forty of these blocks per hour. The boiling solution is thrown against the block by means of two large paddles, and the cylinder blocks leave the other side thoroughly cleansed of all grease and dirt. A few chips may remain, but the man who takes the cylinder blocks out at the other end of the washing machine conveyor has an air hose handy, with which they are blown away. This is illustrated in Fig. 2, where the cylinder block, having passed through the washing machine and been inspected by the workman with the air hose at the end of the machine, is ready to start along the assembly chain, which is shown at the left of the illustration just begining its journey down the line. The closeness with which these blocks follow one another may be realized when we see, in Fig. 2, one block just starting on its journey on the chain, another block being carried over from the washing machine conveyor to the end of the chain by means of the overhead hoist, while the third block has already come out of the washing machine and is ready to be conveyed along the line.

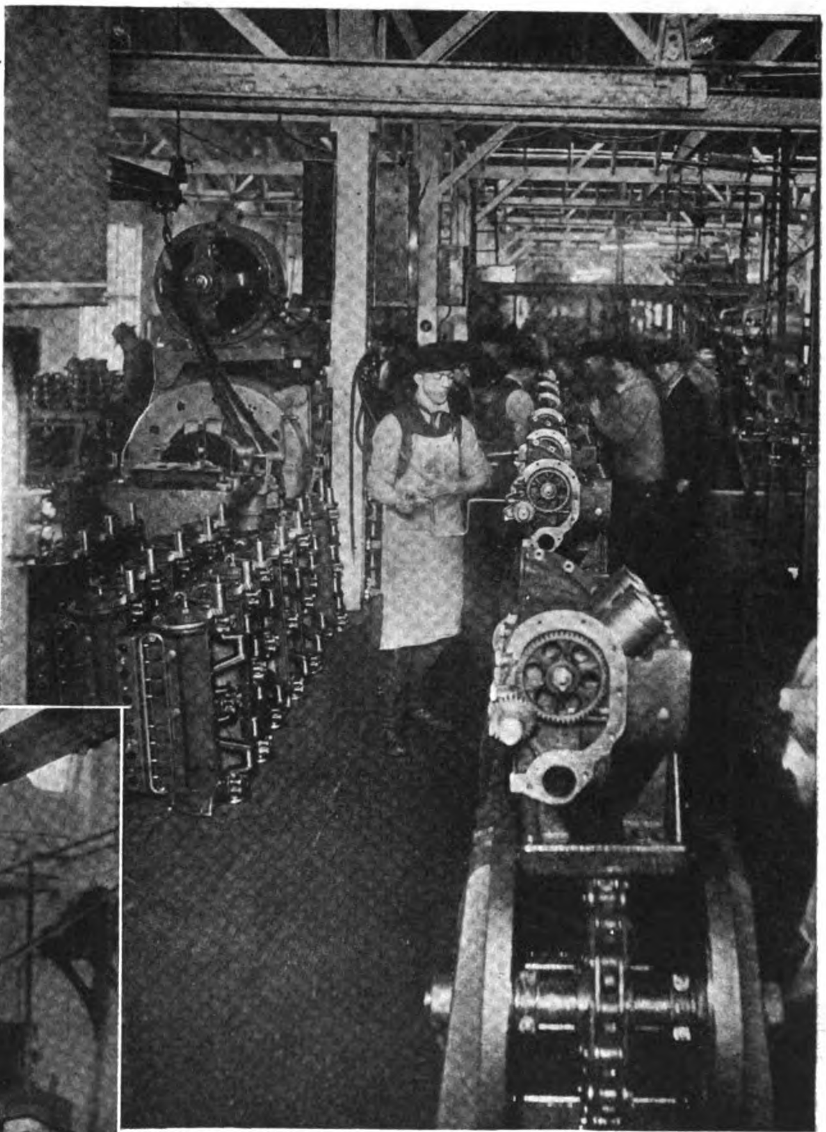

Fig. 7—The second length of the cylinder block assembly chain, showing pistons put loosely on top of block

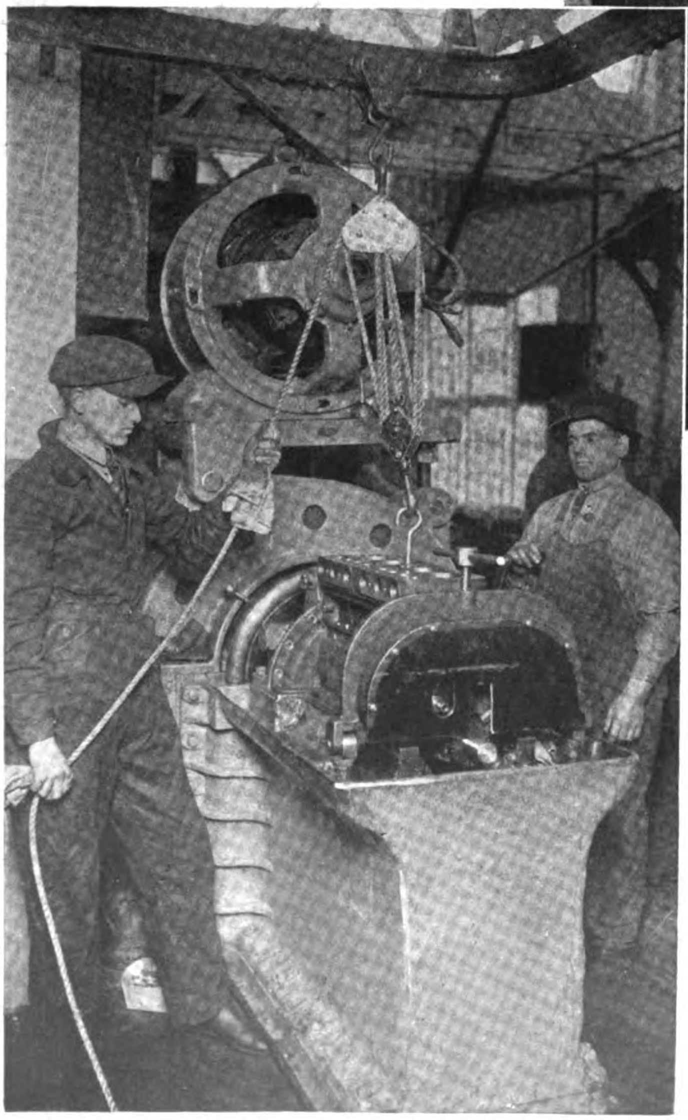

Fig. 6—Cylinder block on the bearing burning-in machine, where the crankshaft bearings are burnished before being finally adjusted

The assembly chain for the cylinder block is in two parts. There is, first, a short chain which carries the block through the preliminary stages of assembly, including the fitting of the crankshaft. Then there is a break in the chain where the crankshaft is "belted in," and, finally the long length of chain which carries the block on to completion.

When the cylinder block is placed on the chain the first operation is to slip the camshaft into place. In the foreground of Fig. 3 is shown a rack which carries the camshafts, placed in a handy position to the operator, who reaches behind, picks up a camshaft and slips it into

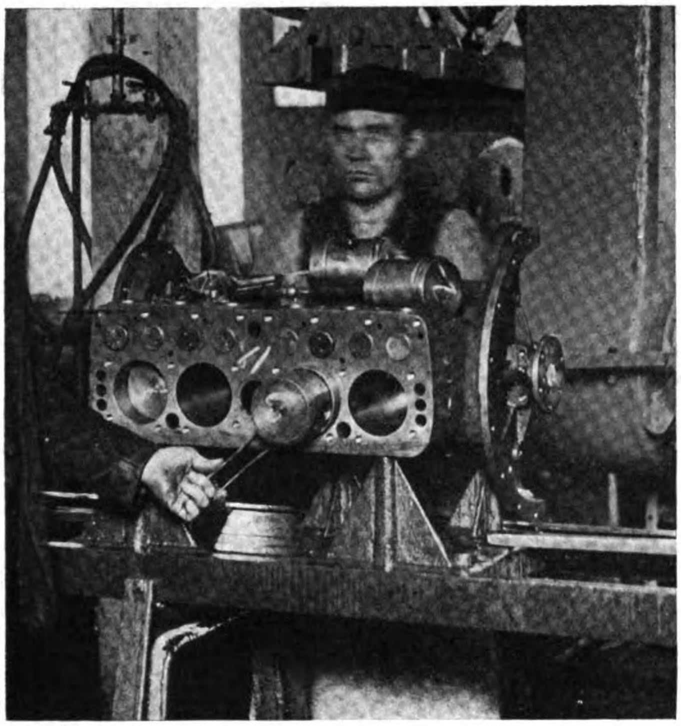

Fig. 8—Note operators on both sides of track, one man slipping piston in and the other putting connecting-rod bearing caps in place

place. He then reaches to another rack in close proximity (not visible in the picture) and picks up a crankshaft and puts it into position.

As will be noted, the timing gears are already in place on the camshaft and the crankshaft. These gears were put on with an arbor press, located close behind the assembly chain, as indicated in the map. The first operator places the camshaft in position and meshes the camshaft timing gear properly with the crankshaft timing gear before the chain carries the block away from him. Whereupon the next operator tightens the main bearing cap screws with five shims under each bearing. After the blocks have traveled about 45 ft. on this first length of assembly chain and have been worked upon by about eight men they come off ready for the bearing "burnishing" machines. Fig. 4 shows most of this length of track. It also shows the arbor press in the background, where the timing gears are pressed onto the crankshaft before they are assembled. This will give an idea of the close proximity of this work to the assembly chain, the head of which can be seen in Fig. 4, and is readily apparent in Figs. 2 and 3.

An interesting feature in the assembly is the method used in burning in the bearings. The engines come off the end of the chain, as shown in Fig. 5, and are immediately lifted up by an overhead L-shaped carrier, shown in the illustration, and carried over to a burnishing machine. One of these, which is not yet in operation, but which will be shortly, is shown in the left foreground. The other can be seen in the background and is more clearly illustrated in Fig. 6. The step illustrated in Fig. 6 is simply a burnishing operation for the crankshaft, there being no pistons or connecting rods in the block. The machine is driven by an electric motor through a large reduction, since the torque necessary to start the crankshaft is very high. It requires about 30 sec. to burnish the bearings, and then the block is ready to go on its way to the next section of assembly chain, where the pistons and connecting rods are assembled.

The blocks are taken off the burnishing machine and slid immediately over to the next section of the conveyor chain for assembly, of which a general view is shown in Fig. 7. Here it will be noticed that men are working on both sides of the chain. This allows two operations to go on at the same time, one on one side and the other on the other side of the engine, and practically doubles the capacity of the conveyor chain.

An instance of this is very noticeable where the pistons and connecting rods are fitted and the caps slipped on. The pistons and connecting rods are slipped in through the top of the block which is lying on the right side of the track, as shown in Fig. 7, while the caps are put on the bottom of the rods, almost simultaneously, from the left side of the track. As the block is put on the beginning of the conveyor chain, shown in Fig. 7, a set of four pistons is picked up by an operator standing at the beginning of the track and laid upon the block. The block shown in the foreground of Fig 7 has these four pistons lying in place. The valves are then slipped in, and as the work progresses the rods, which have been fitted to the pistons, are put in, and the other parts of the engine in the usual order of engine assembly.

At the present time the rods and pistons are assembled on a separate bench alongside the conveyor chain. An operator will pick the set of four pistons off the block, take them over to the bench, fit the rods to them, come

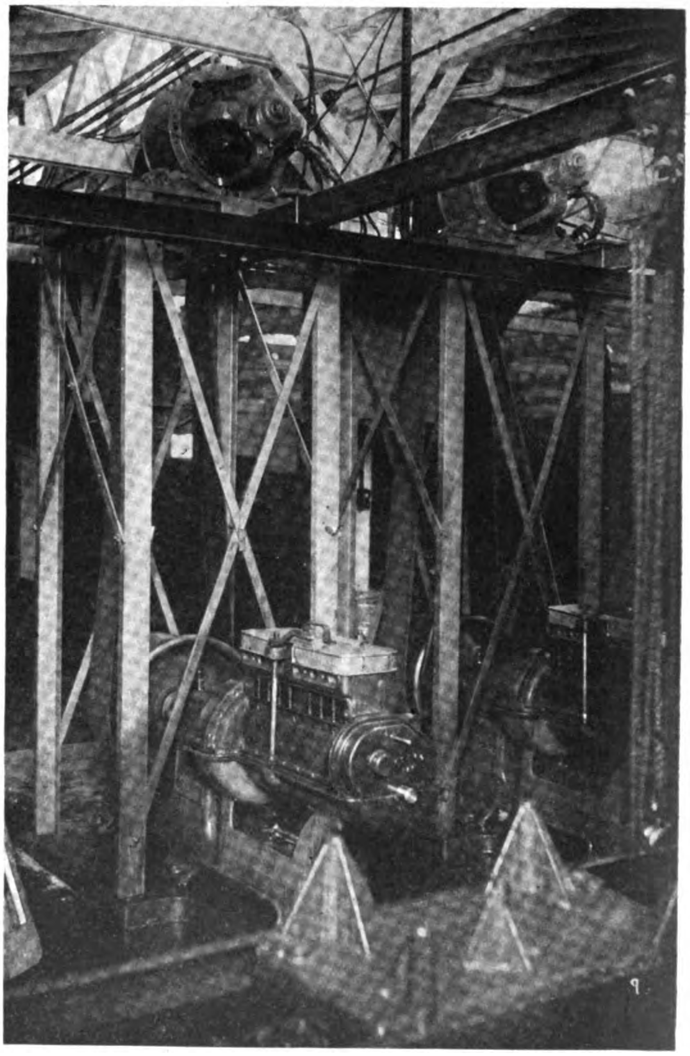

Fig. 9—Belting-in motor with sheet metal top and base formed like oil pan on belting-in machine. There are twelve of these machines to take care of the production

back to the block—which has traveled some distance during his absence—and fit them in place.

Fig. 8 shows the assembled pistons and rods lying on top of the engine blocks. One piston assembly has already been put in place at the left end of the block, while the second is just being fitted. The other two are lying on top of the block. An ingenious pincher-shaped device is used for clamping the rings, so that it is easy to slip the piston into place. This can also be seen in the illustration. As the pistons are slipped in, the operator on the other side of the chain puts the caps into place, inserting the necessary shims for a trial fit, and then taking out the shims necessary to get the engine to turn over properly.

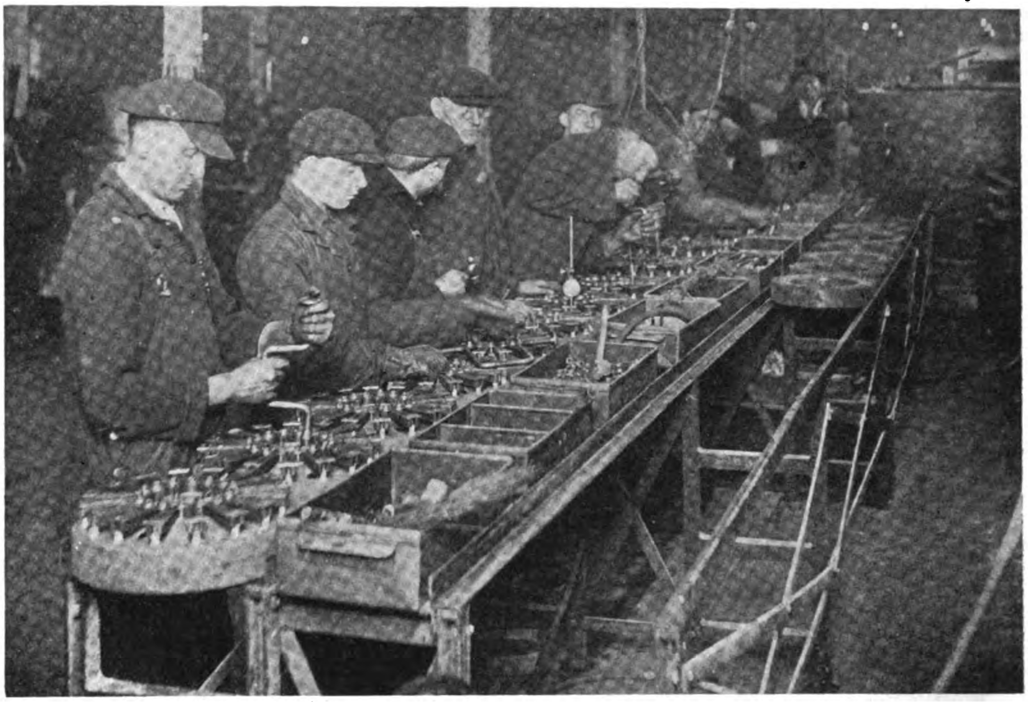

Fig. 10—Sub-assembly of magneto. Note unassembled flywheels on racks and operators working along bench progressively

As the track travels along the operator follows this work himself until he has the bearings properly adjusted; that is, this small portion of the work is not exactly progressive, as the same man fits the bearings from beginning to end, so that he is posted as to the fit and does not leave the next man to make an unnecessary set of experiments to see how tightly the bearings fit before he goes on with the next step in the work. Similarly, one man will follow the connecting rod bearings down through the next belting-in process, traveling along with the chain until he has adjusted the bearing to a satisfactory fit. Fig. 9 shows this belting-in process.

At the present time twelve machines are being used to "belt-in" the engines. These machines have a table, formed exactly like a crankcase, and the engine is mounted directly upon it without the head in place, but with the pistons, valves, shafts and timing gears all completely assembled. In order to stop the oil from splashing out of the tops of the headless block, a sheet-metal head is clamped over the cylinder block. The engine is then given a thorough "belting-in," the length of the run depending on the necessities of each individual case to secure a proper work-in of the bearings. The twelve "belting-in" machines, however, are more than ample to take care of the present production of 300 per day. In

This English truck loaned to the American army is one of many sent to Reconstruction Park for salvage

M. T. C. Salvage Park in France

PART II

An American War Factory in the Heart of France—3500 Employees—Built in 65 Days—Was 120 Miles Behind Front—Engine Department Overhauls 100 Engines Per Week—1000 Jobs Weekly Output—Manufactures New Parts

By W. F. Bradley*

THE statement that the motor salvage park gets out on an average 1000 jobs a week gives little information, for a job may vary from a slight body repair to making several thousand gears, this latter operation comprising the making of the dies, the forging of the blanks, and machining and heat treating. Ford commutators were not coming over in sufficient quantities at one time, so an order was put in for 5000 of these to be made. This constituted a job. A certain four-wheel-drive truck could not be kept supplied with steering arms; thus a job ticket went through for 8000 of these to be forged, machined and bushed. At the beginning of the present winter, hood covers were required, and 13,000 of these were produced in the park.

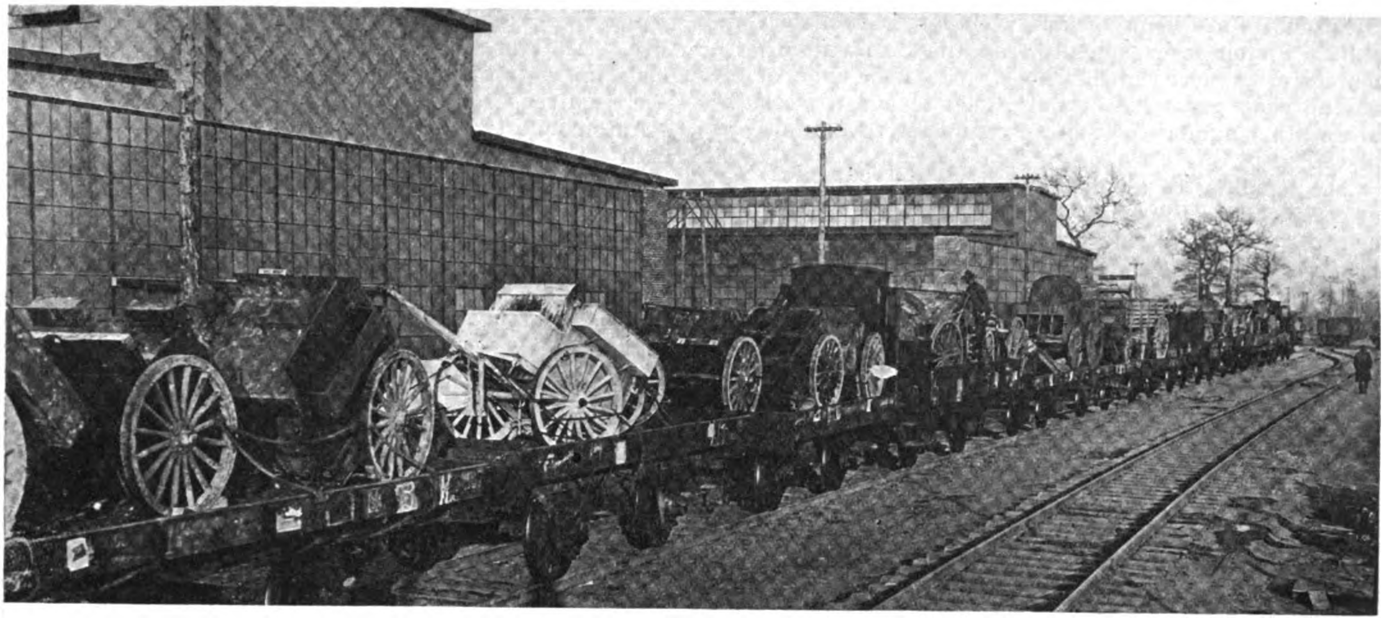
The following will serve to give some idea of the amount of work done in the salvage park. On the week previous to my visit, which was stated to be just a normal week, the staff had completed 78 trucks, which had gone in in all kinds of conditions and had gone out fit for service on the front. It had put 72 light cars into serviceable condition. It had rebuilt 43 motorcycles and 19 bicycles. It had turned out 146 animal-drawn vehicles and completed 363 miscellaneous jobs. These latter might have been anything from a special bushing to several thousands of some part produced on the automatics.

*EDITOR'S NOTE—*W. F. Bradley has studied motor transport during the war in France, Belgium and Italy and has been associated with this department of war since 1914. He assisted in the purchase of many automobiles and trucks for the A. E. F. in the summer of 1917 and personally superintended the overland delivery of many Fiat vehicles for our army. He made a minute investigation of the salvage park described in this article.*

These jobs are really a manufacturing proposition and do not come under the heading of salvage. Work in this field begins with the reception of the wrecked material brought in direct by rail, and by complete train lots from the front. There are probably 5 or 6 miles of track inside the park, so that wrecked material can be handled as rapidly as it is brought in. The task is rendered difficult, however, by reason of the necessity of receiving wreckage while the ground is in course of preparation; a field with railroad tracks through it and no loading platforms does not constitute ideal conditions.

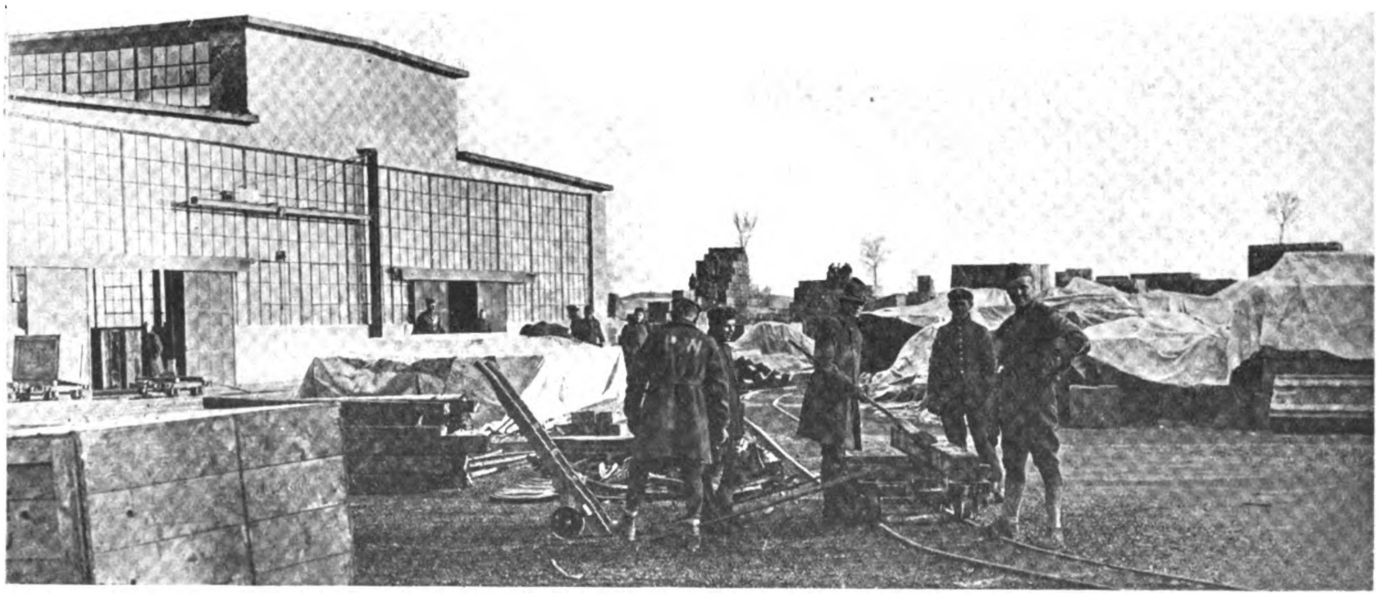
The Salvage Program

The material to be salvaged is either dumped on the ground or lifted out by steam crane and then sorted and passed on by experts. Motorcycles go into one sector; trucks, according to make, into another; touring cars are a separate lot, and Quartermaster horse-drawn vehicles have their own department. An automobile which has been abandoned at the front nearly always reaches the salvage park in skeleton condition. After it has been thrown on one side somebody discovers the need for a magneto. Another person removes the carbureter. A third takes out a few valves or valve caps. All the grease cups are stolen by the natives if they are not removed by the mechanics. Fan belts are never allowed to remain. In nine cases out of ten, when the park receives the automobile it can no longer be treated as a repair job, but has to be handled on salvage lines. Its engine is taken out and sent to the engine shop. There is no work in a factory at home that the salvage park cannot perform.



A trainload of Quartermaster horse-drawn vehicles at Motor Reconstruction Park

Stacks of gasoline drums at Motor Reconstruction Park. These drums were sent in for repair



German prisoners helping unload boxes at Motor Reconstruction Park

Crankshafts are being welded with very satisfactory results. Pistons are expanded, machined and fitted with new rings produced in the shops. When the chief of the engine shop gives his output as 90 to 108 a week, he means this number of motors completely overhauled as above.

The handling of a salvage park of this nature is full of complexity. In comparison, the salvaging of soldiers' clothing, shoes and rifles, of which much has been heard, is mere child's play. The greatest care is necessary in order to produce useful units out of the wreckage which is turned in. Unless there is skilled treatment, a park of this nature will merely accumulate big stocks of certain components and produce very few complete vehicles. The object aimed at is to get out of the wreckage the greatest number of complete vehicles and to have the smallest amount of dead stock. This is far from being a simple task, and although it is being handled in a very intelligent manner, stocks will accumulate.

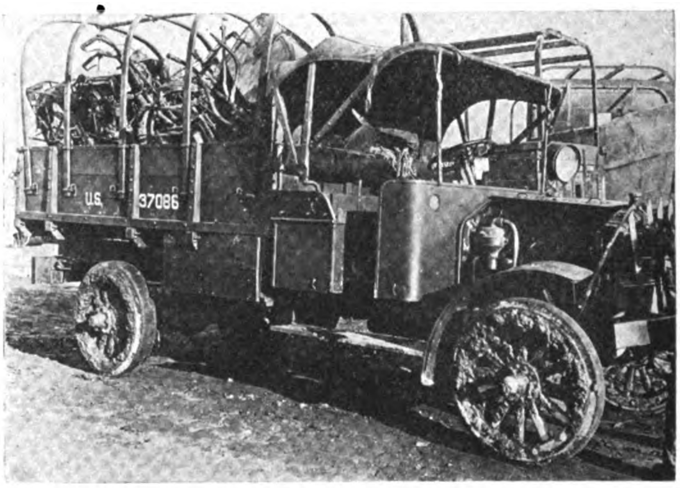
Very much depends on the decision of the officers who pass on the wreckage as it comes into the park. Should the automobile be in fairly good condition, it receives a job number to be rebuilt, in which case it goes out again with its own engine, its own gearset and its own rear axle. Such cases, however, are comparatively few. The next case may be a truck which has caught fire and has had one or more of its wheels destroyed and its frame member warped by heat. In such a case the engine, gearbox and rear axle are ticketed as separate jobs and sent to their respective shops for complete overhaul, after which they go into stock.

Certain parts on an automobile wear out or break and cannot be repaired. Springs come under this category. Therefore a complete spring manufacturing department has to be kept in operation, making for stock the types of springs most needed. Bronze bushings are in practically the same case, and also are in regular manufacture. All kinds of brass and aluminum castings are made in the park, but iron castings are obtained, whenever required, from a French foundry.

Automobile tires are treated in exactly the same way as in the big repair factories at home. After being mended in these shops the tires go into the stores for reissue in exactly the same way as new stock.

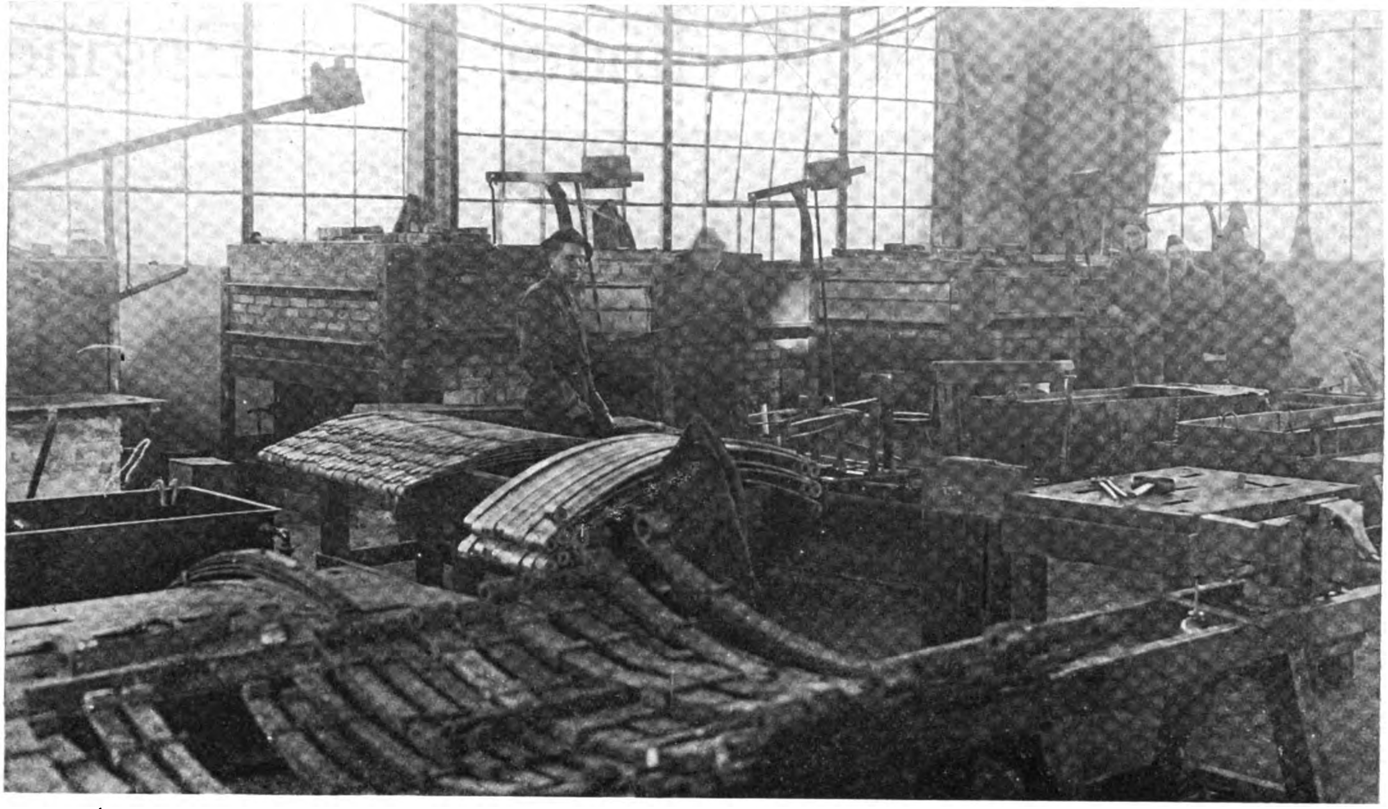
War Storage Depot

In addition to salvaging, the park is designed to act as one of the main automobile supply depots for the forces in the field. The stockroom, 300 by 400 ft., has its 120,000 sq. ft. of floor area divided into alleys, with one class of article in each, and the bins or lockers marked

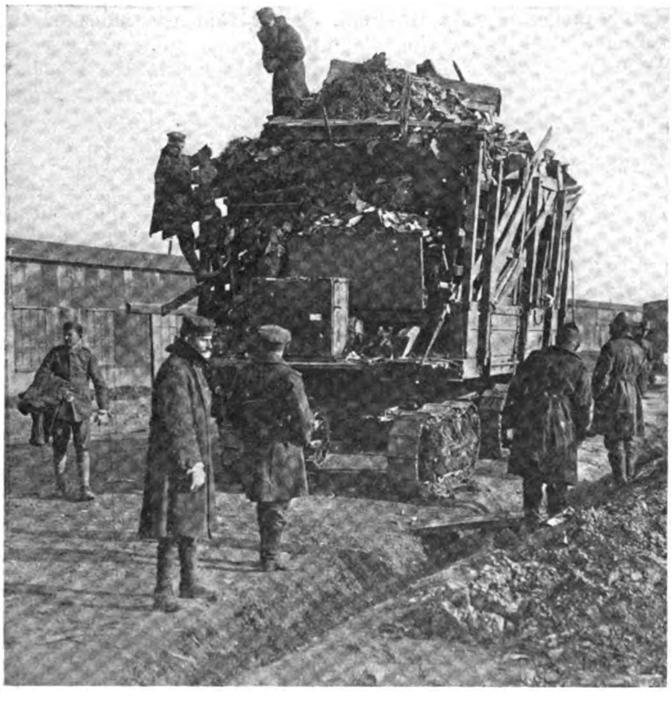


A typical truckload of wrecked motorcycle parts

Part of the main stockroom at Motor Reconstruction Park



Spring-making department at Motor Reconstruction Park



A huge creeper type tractor and its German crew at Motor Reconstruction Park

according to make. The general arrangement is the same as that in the big automobile factories at home, but instead of parts for only one make, there are complete parts for 41 different makes always in stock ready to meet requisitions.

Running along the outside of one end of the main stockroom are car lines from which new goods are received. At the opposite end of the building are dispatching counters with huge boards suspended above them showing Colombey, Dijon, Paris, etc., and immediately outside another set of car lines for dispatching. Everything is up to date, including small electric freight cars for running about the stockroom.

When the salvage park was established there was neither light nor power in the neighborhood. The original intention was to erect a Diesel engine, and preliminary arrangements were made for this, but the supply of crude oil having failed, or its procurement having become difficult, a 1500-hp. steam turbine engine had to be decided on. While the foundations for this were being laid, fourteen G. E. gasoline-electric groups, developing 700 hp., were procured and installed in a temporary building. These engines provided all the light and power for the entire park.

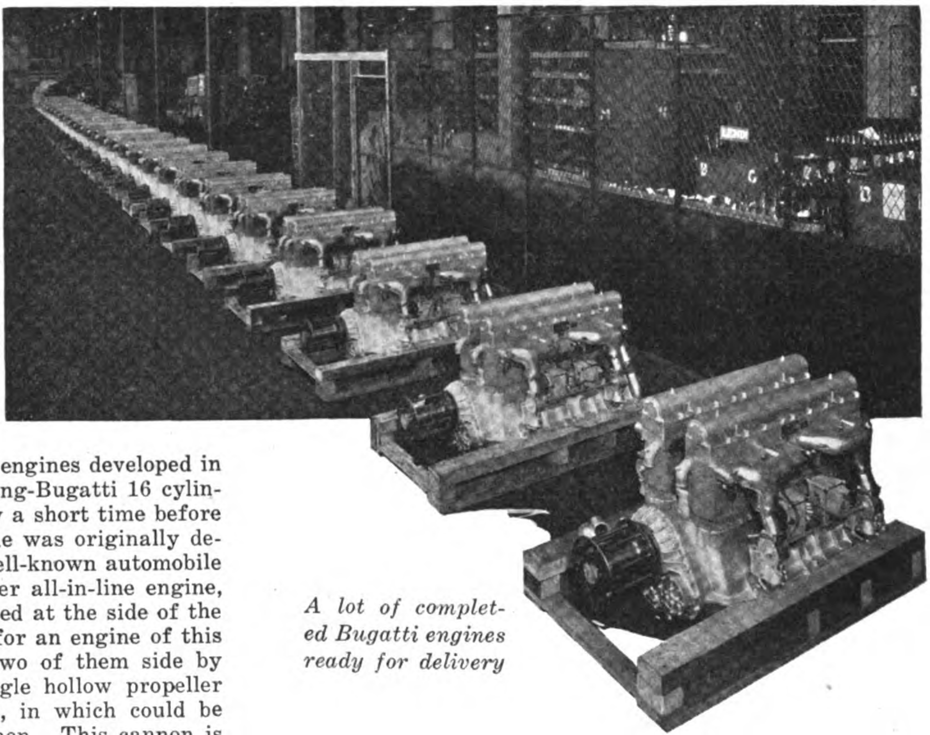
Naturally the park has need of a considerable amount of local transportation. This is covered by 119 trucks, 15 touring cars, 25 motorcycles, 5 Holt tractors, and 7 Holt caterpillar trailers.

ACCORDING to French patent, No. 484,177, of E. Balzarini, a new method is disclosed for improving the action of sparking coils. In the method of construction usually adopted the secondary current often persists after the primary winding has been re-established by the interrupter, and the inverse current at the make suddenly damps out the secondary current that is still flowing, and then reverses its direction. This has several drawbacks, and in particular diminishes the efficiency of the apparatus.

The modification now proposed consists in providing two similar primary windings, put alternately into circuit by the interrupter, the connections being such that the successive primary currents magnetize the core of the sparking coil in opposite directions. Thus the electromotive force in the secondary circuit at the make agrees in direction with the existing flow of current. The result is that the current in the secondary circuit is rectified by a high-tension commutator. It would seem, though, that any advantages gained would be discounted by the reduction in efficiency due to the use of double primary coils.

King-Bugatti 16-Cylinder Aero Engine

Consists Virtually of Two 8-Cylinder All-in-Line Engines Mounted on a Common Crankcase and Geared to a Common Propeller Shaft—Designed to Permit 37-Mm. Cannon to Shoot Through Hollow Propeller Shaft



A lot of completed Bugatti engines ready for delivery

ONE of the most interesting aviation engines developed in connection with the war was the King-Bugatti 16 cylinder, which went into production only a short time before the signing of the armistice. This engine was originally developed in France by Ettore Bugatti, a well-known automobile designer. Bugatti first built an 8-cylinder all-in-line engine, with a geared-down propeller shaft, located at the side of the engine. There was found to be no need for an engine of this type, and so Bugatti décided to place two of them side by side, on a single crankcase, using a single hollow propeller shaft between the two sets of cylinders, in which could be mounted a standard French 37-mm. cannon. This cannon is loaded with buckshot, and its use had been proven very efficient by Guynemer, hence it had been decided to build planes on which this cannon could be mounted.

Bugatti then built a 16-cylinder experimental engine, which was tested in France on the block, and later was brought to this country together with the 8-cylinder model, the two being taken to Dayton, Ohio. The 16-cylinder engine broke down at once on the dynamometer test and developed serious defects, such as a crack between the valve seats in the cylinder castings and improper operation of the lubricating system. The engine was at once rebuilt by the French engineers who were sent along by Bugatti. In the meantime, it was realized that the engine was not a production job, and the defects mentioned, as well as structural weaknesses in the propeller shaft mounting, made it necessary to completely redesign it. This task was entrusted to Charles B. King.

The new design incorporated pressure lubrication, a ball-bearing mounting of the propeller shaft, a dry crankcase system, cylinder castings so made that the valve seats were properly cooled, water spaces in the casting cored out instead of being drilled out as in the French design, etc.

An engine to this design was built at the works of the Duesenberg Motors Corporation in Elizabeth, N. J. At the time the rebuilding of the French engine was completed, the first King-Bugatti engine was also ready for the test block. A one-hour full power test was made on the French engine, and horsepower curves were plotted, after which the engine was removed from the test block and put in storage as Government property. The King-Bugatti was then put on the test stand and given a very thorough test. Production of King-Bugatti engines was begun at the Duesenberg plant, and at the time the armistice was signed 40 engines had been officially tested and accepted by the Government.

With a cylinder bore of 110 mm. and stroke of 160 mm. (4.33 x 6.3 in.), the engine has a piston displacement of 1484.3 cu. in. The first engine accepted by the Government was put through a 50-hr. block test with a club. It ran through ten periods of 5 hr. each, consisting of ½ hour's running at 410 hp. at 2000 r.p.m., and 4½ hours' running at 369 hp. at 1886 r.p.m. The compression ratio used is 5:1.

The cylinders are of iron, cast in blocks of four. They are bolted to the crankcase without the use of a gasket. The water jacket is cast integral, except that the sides of the cylinder block below the inlet and exhaust ports are covered with a cast aluminum plate fastened by screws and packed with a gasket. The cylinders are cast with separate exhaust ports. One inlet port supplies two cylinders. Two outlet and one exhaust valves are used.

The entire combustion space is machined, with the exception of a very small recess near the inlet valve seat. The tops of the cylinder blocks are machined, making an oil-tight joint with the camshaft housing without the use of a gasket.

Provision is made for a liberal circulation of water in the neighborhood of the valve ports, seats and guides. There are two spark plugs per cylinder, which are located at the side of the combustion chamber in close proximity to the inlet valves, and are well cooled by the circulating water.

Crankcase

The crankcase and oil pan are of cast aluminum. The case is well ribbed. All bearings are supported from the upper part of the case, the bearing bushings being held in place by caps which extend almost the full width of the case. Each cap supports two bearings. They are all of cast aluminum, with the exception of the center bearing cap, which takes all the thrust of the crankshaft. This is a steel forging.

The oil pan has a central web running its entire length. This greatly assists in preventing the current of air caused by the revolving crankshafts from drawing up the oil which is constantly draining into the pan. There is also a cross web between each cylinder block which runs well up the sides of the oil pan. These cross webs have an opening at the bottom at their center, allowing the oil to drain to the ends of the pan on either side of the web running lengthwise. A breather is attached to the top of the crankcase near the front end between the cylinder blocks.

Provision is made at the rear end of the case for attaching a 37-mm. cannon, the barrel of the cannon projecting through the hollow propeller shaft.

The piston is of aluminum and has two ring grooves above the piston pin. Two ⅛-in. wide rings are placed in each of these grooves. The rings require a pressure of 10 to 12 lb.

applied on a diameter at right angles to the slot to bring the ends of the 30-deg. slot to within 0.010 in. of the closed position. The lower ring is beveled, being placed in the groove with the sharp edge down so that it acts as a wipe ring, forcing the oil on the down stroke into an oil groove cut just below the ring groove. The land between the bottom of the ring groove and the oil groove is 1/64 in. wide and it is 1/32 in. smaller in diameter than the land above this ring groove. This forms a free passage for the oil to the oil-collecting groove. Eight 3/32-in. holes are drilled around the piston, connecting the oil groove with the interior of the piston. These holes slope down at an angle of 60 deg. with the axis of the piston, carrying the oil wiped from the cylinder wall to the interior of the piston. A slot ⅛ in. wide by 1/16 in. deep is cut from the oil groove to the piston pin hole at both ends, thus lubricating these bearings. Two ½ in. wide by 1/32 in. deep oil distributing grooves are cut around the piston.

Piston Pin

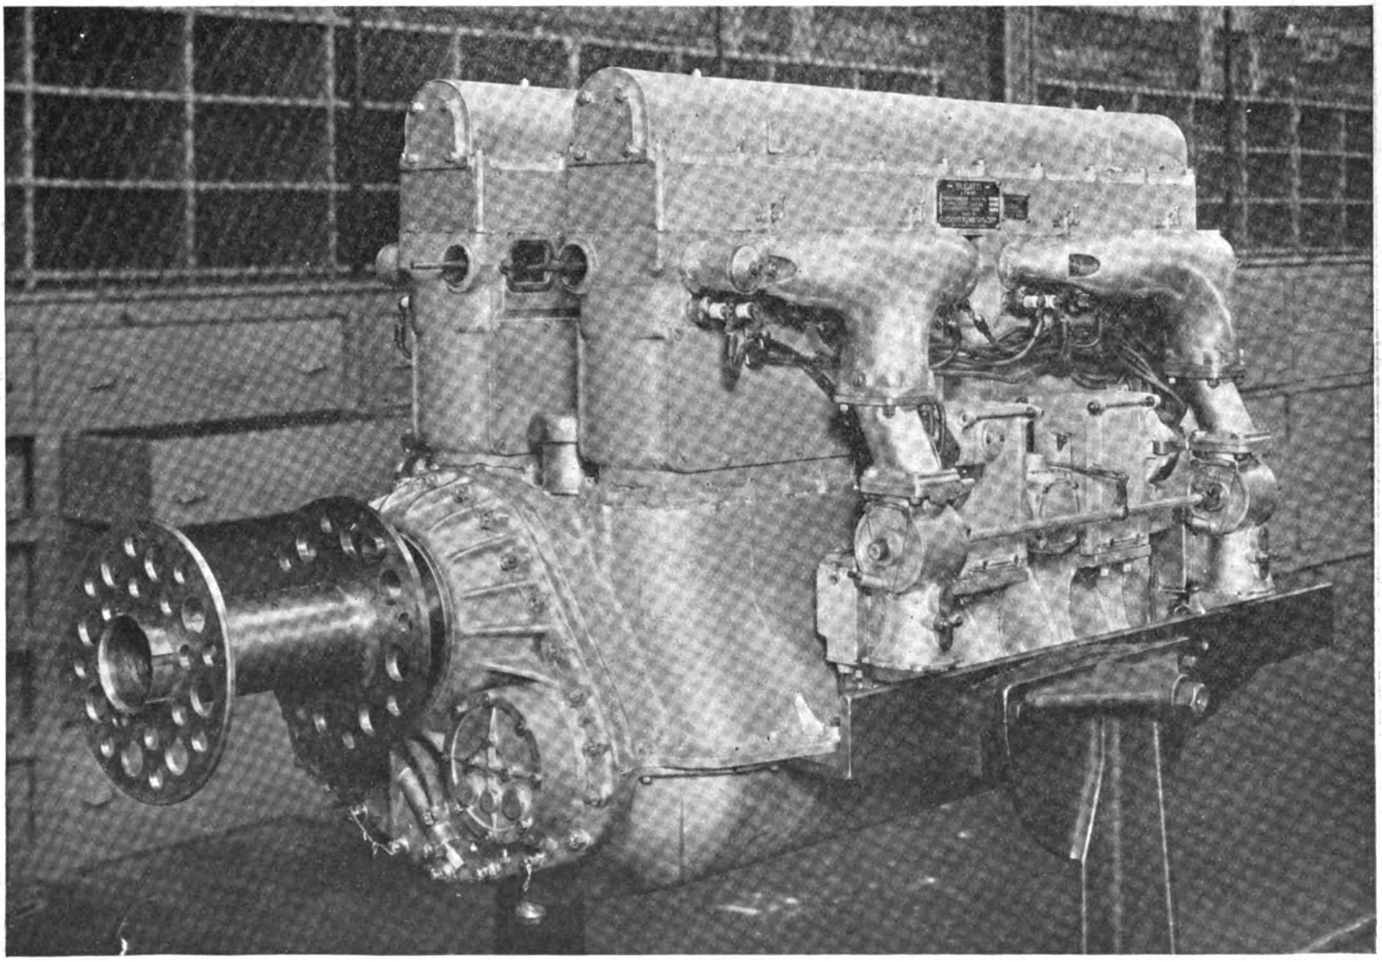
The piston pin floats in both the connecting-rod bushing and the piston. Bearing in the piston is directly on the aluminum. It is held from endwise motion by an aluminum plug pressed into each end. These plugs are drilled axially with a ⅜-in. hole which allows a certain amount of oil from the cylinder wall to enter the hollow piston pin. The ends of these plugs where they bear against the cylinder wall are turned to a spherical seat of a radius equal to the radius of the cylinder bore. In operation the piston pins turn more or less. Two ⅛-in. holes are drilled through the wall of the pin. These holes, when in a certain position, register with an oil groove in the connecting-rod bushing, allowing a certain amount of oil to enter the hollow piston pin, and when in the lower position allow the oil which is pocketed in the pin to run out onto the connecting-rod bearing.

The connecting rod is a steel forging machined all over. It is of H cross-section. The small end bearing is a bronze bushing pressed in position, having one straight oil groove 3/32 in. wide by 1/32 in. deep, running to within ¼ in. of the ends of the bushing. This groove is in communication with a 13/32-in. drilled hole in the connecting rod through a ⅛-in. hole. Oil collects in the pocket formed by the 13/32-in. hole and is led to the bearing through the ⅛-in. hole.

The big end of the connecting rod is fitted with a bronze bushing which is babbitt lined. This end is split at right angles to the rod on the center line of the bearing, the cap being held in position by two ⅜-in. chrome nickel steel bolts. The bushing is relieved at the parting line by five grooves, 3/16 in. wide, about ¾ in. long, 3/64 in. deep, cut on a 7/16-in. radius with a center on the parting line. The rod half of the bushing has no oil groove; the cap half has a circular oil groove entirely around it cut on the center line of the bushing and registering with the oil feed hole in the crankpin. This groove is ⅛ in. wide by 1/32 in. deep. The bushing in the cap is kept from turning by a dowel pin with an enlarged head. This head enters a countersunk hole in the cap, the small end entering the hole in the bushing when it is placed in position. This end is of such a length that it does not project through the bushing. The pin is thus locked in position and cannot drop out on the shaft.

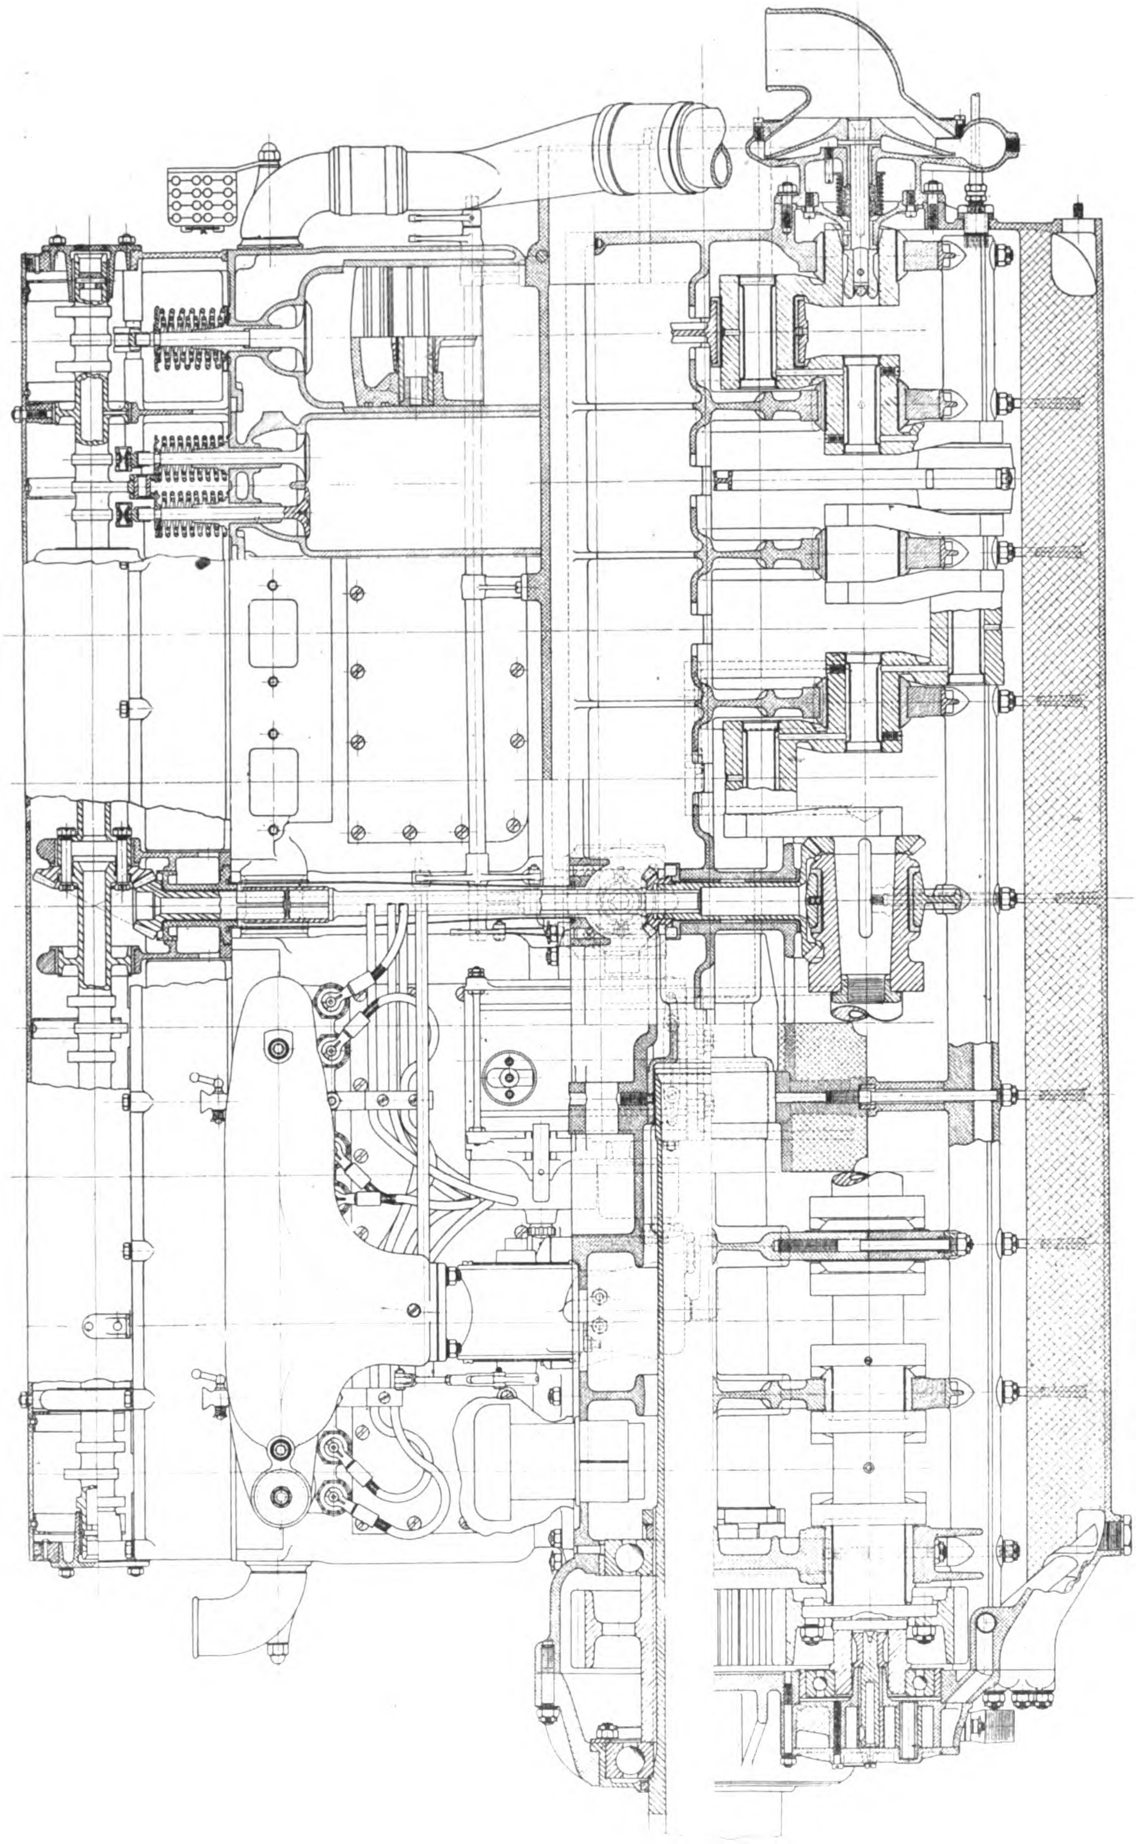
Crankshaft

The crankshaft is made in two pieces, connected at the center by a taper and key drawn up with a nut. Each section of the shaft forms a four-cylinder shaft with the throws all in one plane, the throws of the two sections being assembled at right angles. In assembling, the rear end of the front half is immersed in boiling water; the tapered end of the rear section, which is cold, is then slipped into position, and the parts are drawn together by the nut, using a long-handled wrench. The rear end of each complete shaft has clutch teeth cut on it for attaching a starter.



The 16-cylinder King-Bugatti engine, viewed from the propeller end

Bugatti 16-Cylinder Engine in Section



This engine has a bore of 110 and a stroke of 160 mm. The above sectioned elevation shows numerous details of construction

All end thrust coming on the shaft is taken by the center bearing, all other bearings having about 1/16 in. clearance at both ends. All bearings, including the connecting-rod bearings, with the exception of the center main bearing, are undercut. This results in a total shortening of the shaft of approximately 4 31/32 in. and in a considerable saving in weight.

The crankshaft main bearings are bronze bushings, babbitt lined. These bearings are not relieved at the parting line, and there are oil grooves only in the lower halves of all but the center bearing. These have a 3/32 in. wide by 1/32 in. deep circular oil groove entirely around them. This groove registers with the oil hole into the hollow crankshaft bearing. As this oil hole is drilled through both walls of the bearing on a diameter and as the oil groove in the bushing extends through 180 deg., there is aways a free passage for the oil from the bearing into the hollow crankshaft.

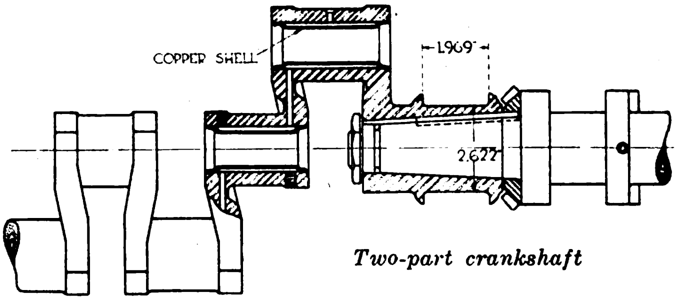
In assembling the completed crankshafts in the crankcase, they are placed in such relation to each other that if No. 8 throw left is on top dead center No. 8 throw right will be 45 deg. past bottom dead center. Both cranks turn clockwise viewed from the rear of the engine.

The propeller driving gears are bolted to the crankshaft with nine bolts equally spaced, the bolt holes being drilled in a certain relation to the gear teeth. This makes it possible to use the same gear on either shaft, with a maximum error in the setting of the shafts of 20 minutes.

Valves

The inlet and exhaust valves work in cast-iron guides pressed into the cylinders. Liberal water space is provided in the cylinder head in the neighborhood of these guides.

The exhaust valve stem is hollow from the head to within a short distance of the necked portion at the upper end. The hole is closed at the head end by a short, threaded plug screwed in below the surface of the valve, the recess then being filled level with the surface of the valve by welding. This closes the hole tightly and locks the plug in position. The lower end of the exhaust valve stem is of larger diameter than the upper end. Both the large and small diameters take a bearing in the valve guide. At the shoulder formed by the junction of the two sizes of stem three 3/32-in. holes are drilled at an angle of 30 deg. with the axis of the stem, sloping toward the head of the valve and connecting with the drilled hole in the stem. At the upper end of the stem just below the necked portion a 5/32-in. hole is drilled through



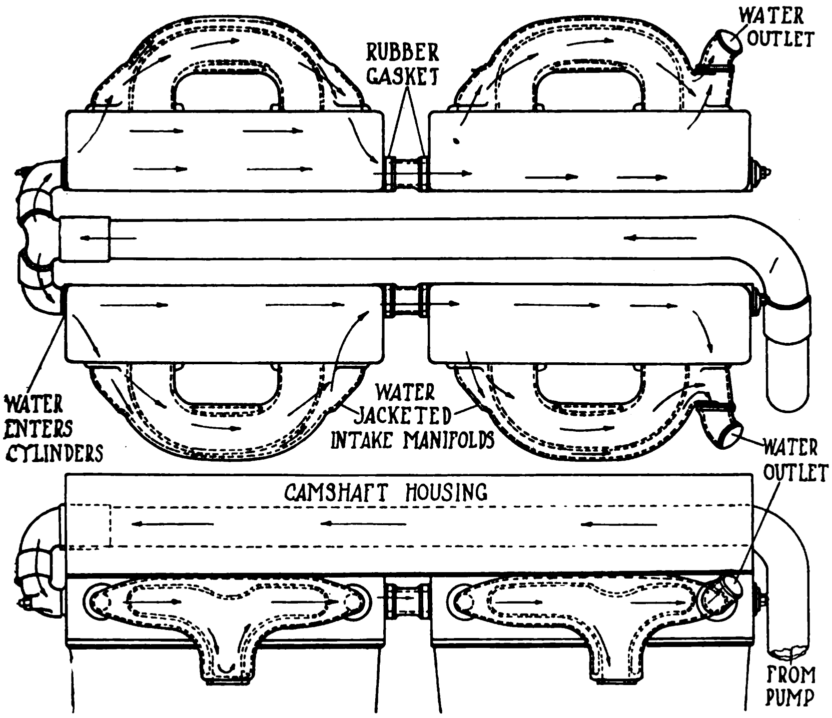
Two-part crankshaft

the wall of the stem. The movement of the valve up and down in the guide causes a pumping action, the transfer of air within the valve stem being thought to cool the steam to a certain extent. This drilling also lightens the valve.

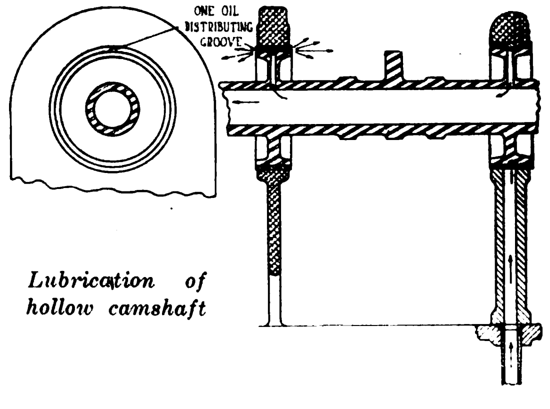
The valves are operated by an overhead camshaft through a rocker arm. These rocker arms are pivoted on steel shafts which are slid into drilled holes along both sides of the camshaft housing. There are four of these rods to each housing, each one-half the length of the housing. The ends of the rods butt together at the center, the outer ends being flush with the ends of the camshaft housing and covered by the end bearing support for the camshaft when this is bolted in position. The rods are thus prevented from moving lengthwise. They are a tight enough fit in the drilled hole in the camshaft housing so that there is no turning motion. The outer end of each rod is tapped for a wrench to be used in withdrawing the rods from the housing.

Each rocker arm operates one valve. The arms are forgings and the pivot bearing on the rod in the camshaft housing is not bushed. The cam operates on the large roller, which is of hardened steel, taking a bearing on the hardened steel pin. This pin is held in the rocker arm by spinning the metal of the arm around the beveled end of the pin. The small roller operates directly on a cap placed over the end of the valve stem. This roller is of hardened steel and takes a bearing on a hardened steel pin the ends of which are soft and spun over into a bevel at the outer edges of the hole in the rocker arm.

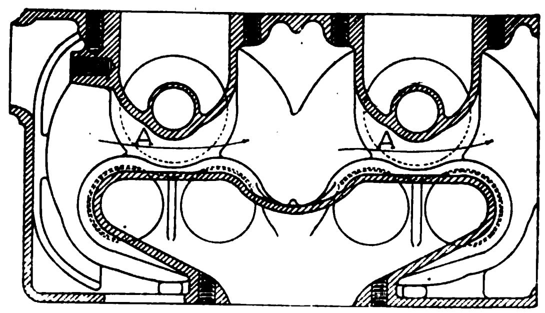
The end of the valve stem has a cap slipped over it, the upper end of the cap being hardened. The proper clearance, 0.015 in. for both the inlet and exhaust valves, is obtained by placing shims in the cap. Three different steel shims are used of 0.003 in., 0.005 in. and 0.010 in. thickness, the first



Illustrating direction of water flow



Lubrication of hollow camshaft



Cooling of the valves

being octagonal, the second hexagonal and the third round, so that the different thicknesses may easily be picked out by eye.

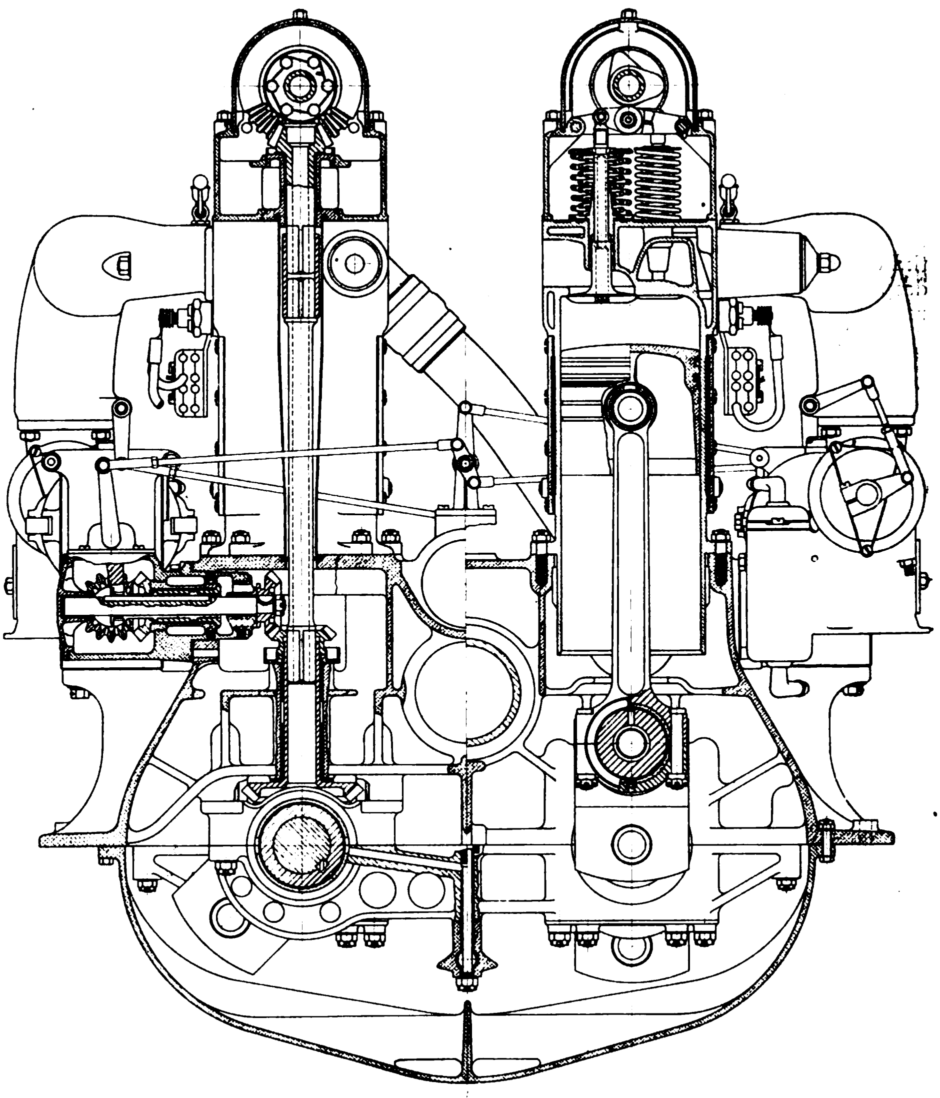
The upper valve spring retainers have a central tapered hole, the large end being on top. The valve stems are necked, and a tapered split collar is slipped into the necked portion of the stem, large end up. This taper is the same as that of the hole in the spring retainer. The pressure of the valve springs forces the retainer against the tapered collar, which is prevented from moving by the shoulder on the valve stem, thus locking the retainers into position.

Camshaft Drive

There are two overhead camshafts, each one running the full length of the two cylinder blocks. Each shaft is made of two separate shafts joined near the center by six bolts passing through flanges on the shaft. These bolts also hold the camshaft gear in position. Each complete shaft is carried in ten plain bearings in a removable camshaft housing. The two housings are of aluminum and each one is bolted directly to the top of the cylinder blocks without the use of a gasket by twenty ¼-in. studs.

The first camshaft housings had a sheet aluminum cover, but a later housing is made entirely of cast aluminum with a cast aluminum cover plate at the side running the entire length of the housing.

Each camshaft is operated through a bevel gear driven by a vertical shaft between the two cylinder blocks, which in turn is driven by a bevel gear on the crankshaft. The gear on the crankshaft is pressed in position and in addition is held by a key. The thrust of this gear is taken by the crankshaft center bearing. This gear meshes with a bevel gear which drives the vertical shaft, the thrust of the gear being taken on a bronze, babbitt-lined bushing pressed into the aluminum crankcase. This gear has a long shank which acts as a bearing for the gear, and has a fine external thread cut at its upper end. This upper end has a square broached hole, the hole having a definite relation to a marked tooth of the gear. The bearing for the upper end of the shank of this gear is a bronze bushing, babbitt lined, pressed into the crankcase. The upper end of the bearing is cupped to form an oil well which catches the spray in the crankcase which is led to the bearing. The magneto driving shaft driving gear is screwed onto the thread at the upper end of the shank, the adjustment of the gear being obtained by means of the thread.



Transverse section of engine, showing camshaft and magneto drive

This gear has a square broached hole, the same size as the hole in the shank of the gear it is screwed to, and is locked in position by dropping the camshaft driving shaft into position, this shaft having a squared section at both ends, the lower end fitting into the square hole in the magneto driving shaft driving gear and the square hole of the shank of the camshaft driving shaft gear. The gear on the camshaft meshes with a gear having a long shank with a squared section at its lower end, the square being cut with a definite relation to a marked tooth on the gear. This gear takes a bearing in an aluminum, babbitt-lined bushing which is held in position in the camshaft housing by a large, flat-head screw.

This bushing also takes the thrust of the bevel gear. The upper end of the vertical camshaft driving shaft and the lower end of the camshaft driving gear are connected by a coupling consisting of a square piece of steel with a square broached hole fitting over these square ends.

The teeth of all the gears being marked for the meshing position, they may be easily assembled in the proper positions for correct timing. (*To be continued*)

French Tractor Results

ON a certain farm in the Seine-et-Oise Department of France (says *Le Genie Civil*) a State-owned Titan tractor of 20 hp. carried out part of the reaping at the agreed contract price of $6.75 per acre, this price including hire of tractor, driver, oil, grease, and twine. It cut 62.5 acres of winter wheat, 37.5 acres of spring wheat and 27.5 acres of oats, a total of 127.5 acres. The winter wheat, which was a very thick growth, was particularly difficult to reap. It was sometimes only possible to work on three, and even two sides, thus increasing the fuel consumption. The other expenses of the farmer were 80 cents per acre which, added to the $6.75 agreed price, makes $7.55 per acre. The work done per day was only 7½ acres.

On another farm a 20-hp. Titan tractor reaped a quarter of the crop—136 acres out of 544. The tractor operated a McCormick reaper of 7 ft. cutting-length. The ground being level in this case, it would have been possible to make the tractor drive a reaper-binder of 9.2 ft. cutting-length, or even two ordinary reaper-binders. Not counting binder twine, the cost of work with the tractor came out at $3.18 per acre, while animal traction only cost $3. This slight difference is more than compensated for by the increased speed of working.

The Engine of the Side Car Motorcycle

PART II

An Analysis of Features of Cycle Engine Construction in a Paper Presented to the Institution of Automobile Engineers by E. Caudwell

THE internal cam, which has been largely favored, while it has certain advantages in permitting the use of rather longer bearings with a more compact timing gear, has not much else to recommend it.

Fig. 3 shows the exhaust cam and rocker of a well known engine, and Fig. 4 the lift, velocity and acceleration curves, plotted for 3000 r.p.m. of the crankshaft. It will be noted that the lift curve is unsymmetrical, due to the displacement of the roller in relation to the center of the cam. The roller moves on an arc about the rocker center, and this causes it to approach the cam as the valve lifts and to recede as it closes. The velocity therefore rises to a higher value during the opening period. Most interest is attached to the acceleration curve. As the valve is opening this rises to 6000 ft. per second per second. Taking the weight of the moving parts at 0.7 lb., it requires a spring strength of 130 lb. to compel the valve to follow the cam.

Since such a spring is a practical impossibility for this size of engine, it follows that the valve jumps at this point and then lags behind the cam. As the valve is closing, the lift curve, instead of approaching the base line asymptotically, cuts across it, indicating such an extremely rapid change of velocity that the acceleration curve runs up toward infinity, approximating to a rectangular hyperbola, so that its final values cannot be plotted. While this effect is reduced by the elasticity of the parts and the lag of the valve, it is clear that the valve closes with a considerable amount of shock and noise, while it is worth noting that engines with internal cams have always been the worst offenders in breaking valves.

A constant acceleration cam is also shown. The spring strength required for this is 58 lb., and though the areas during opening and closing are not so large, there would be a considerable gain in efficiency, quiet running, and probably increased power at high speed, since the timing would be more accurate.

These diagrams also show why, when tuning up an engine for high speed work, the first thing to do is to enormously strengthen the valve springs.

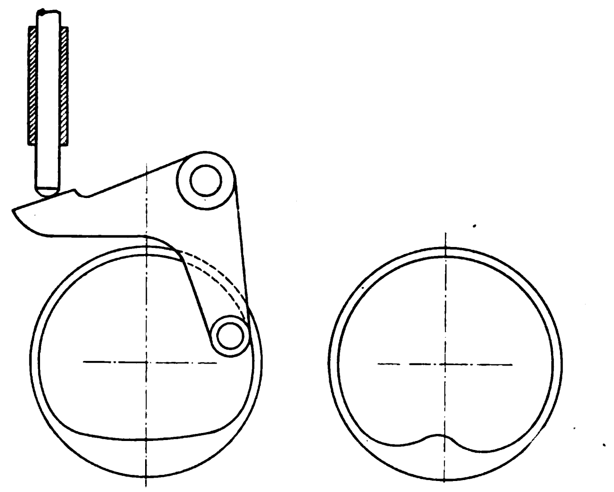


Fig. 3—Exhaust cam and rocker of well-known motorcycle engine

Tappets also have an extraordinarily short life, and after a few hundred miles running develop a large amount of side play. This is often aggravated by the offsetting of the valve from the center of the tappet, resulting in very heavy side loads, while the diameter of the tappet is always much too small, frequently being only 6 mm.

It should be noted that a flat twin engine and a four-cylinder engine both permit of good design of the valve gear; in the former case a camshaft can be mounted in the crankcase over the crankshaft with plenty of room for ball bearings, and a good width of timing wheel and cams.

The four-cylinder engine with its valve gear in front is also practically unrestricted, so that there are no difficulties in the way of bringing the valve gear for these types up to car standards.

Weights of Engines

The single-cylinder engine is the heaviest of any type for its power output. This is largely on account of the heavy flywheels required, especially when placed inside the crankcase. One popular engine weighs 68 lb., but the average for most other makes is 85 lb. The Vee twin-cylinder engines are somewhat better, the average weight being about 100 lb. for a one liter engine (61 cu. cm.).

No weights are available for the flat twin engine, but it should have a good power-weight ratio on account of its small crankcase and large and therefore light flywheel.

These engines all require an unnecessarily heavy transmission on account of the fluctuations in crank effort, and this should be borne in mind when judging an engine on the question of weight.

The four-cylinder engine is the lightest of all, and its even crank effort and adaptability to a high speed gearbox have a large effect in reducing the weight of the transmission. The four-cylinder Henderson engine is the largest in use to-day, having a piston displacement of 1170 c.c. Yet the complete power plant—engine, clutch and gearbox, with kick starter, magneto, carbureter and muffler—only weighs 128 lb.

The ratio of bore to stroke is a matter on which little originality has been shown. About a decade ago, when the A. C. U. fixed 500 c.c. as the limit in capacity for the 3½-hp.

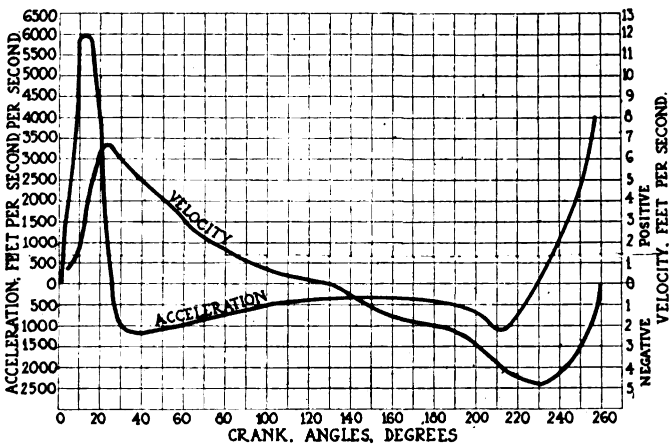

Fig. 4—Lift, velocity and acceleration curves for 3000 r.p.m. of the crankshaft

Four-Cylinder Henderson Engine

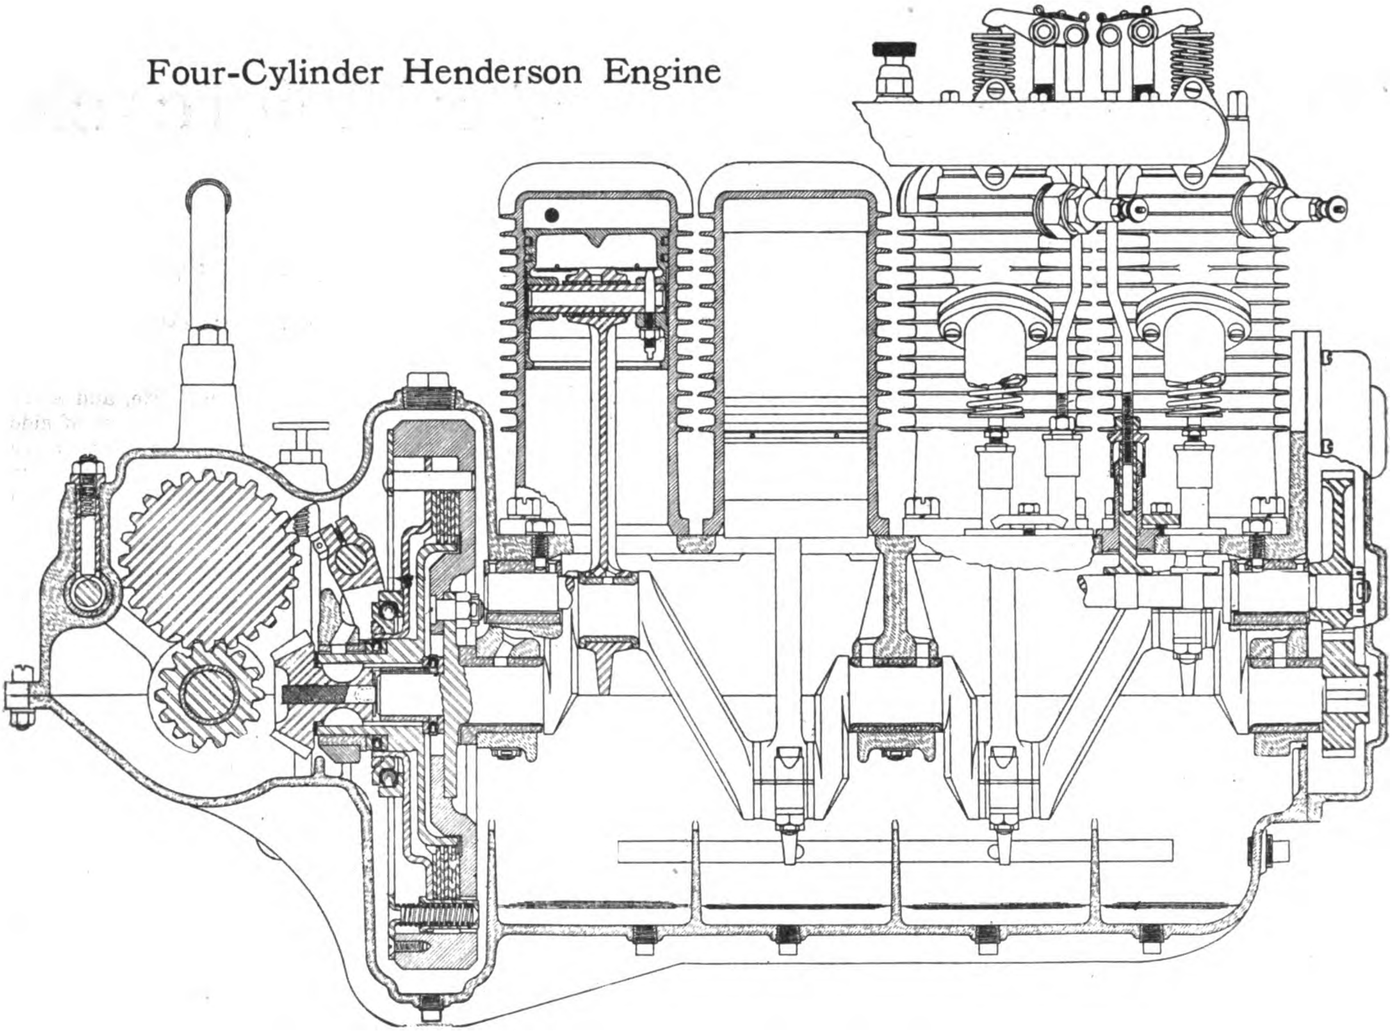

Fig. 5—Longitudinal section through Henderson engine, clutch and gearbox

class in races and competitions, one well known maker gained numerous successes with an engine 85 mm. bore by 88 mm. stroke. As a consequence this engine was treated with the sincerest form of flattery, namely, imitation, and many people since then seem to have regarded these dimensions as a sort of standard. Aside from one or two notable exceptions, there is no sign that any effort has been made to improve design by an alteration in the stroke-bore ratio, although with car engines average practice has settled down to the employment of a stroke 1.5 times the bore. Theoretically, neither balance nor crank effort is affected by the stroke, as the unbalanced force depends entirely on the point in the stroke at which the connecting-rod and crank are at right angles, *i. e.*, the ratio of connecting-rod length to stroke. For any given piston swept volume the crank effort and torque are also both independent of the stroke, as may be seen by an inspection of the fundamental horsepower formula P.L.A.N/33,000, which shows that for any given speed of revolution and any given mean effective pressure, the horsepower developed depends on L $\times$ A; in other words, the volume of the cylinder, so that if this is a constant, the power output must always be the same, and cannot be affected by the ratio of L to A.

It is often stated that a long stroke engine pulls better than a short stroke engine, but other conditions being equal this idea is a fallacy, because the average crank effort or torque is a function of the horsepower, being in inch-lb. for a four-stroke engine 63,025 times the horsepower divided by the revolutions per minute. So we see that the torque also is constant for any given volume of piston displacement, and is independent of the length of stroke and area of the piston so long as they produce the constant volume.

However, a lengthened stroke has a good effect in smoothing out the crank effort curve, as a small reduction in the cylinder diameter means a considerable increase in the stroke without a proportionate decrease in the weight of the reciprocating parts. Since the acceleration is proportionate to the stroke, we get a larger relative inertia force, which has the effect of reducing the peaks on the crank effort diagram, and therefore the ratio of the mean effort to the maximum variations. As it is generally convenient to employ a relatively shorter connecting-rod on a long stroke engine, this increases the aforementioned effect, since, as the ratio of connecting-rod length to stroke is decreased, the inertia forces become larger during the first and smaller during the second portion of the stroke. A longer stroke also gives a larger wall area for cooling surface. Further, for a limited width of engine, a decrease in the cylinder diameter is distinctly advantageous to other aspects of the design, allowing more space for adequate sizes of the valve operating mechanism.

In order to show that it is possible to build a power unit complying in a large measure with the conditions laid down at the commencement of this paper, Figs. 7 and 8 give longitudinal and cross sections of the 7-hp. F. N. engine. The bore and stroke are 52 mm. and 88 mm. respectively, and an inspection of the drawings will show that the engine contains all the usual features of a light car engine with the same relative proportions. The general layout of the machine is also on car lines, a flywheel, a clutch, a three-speed gearbox, and a final drive by shaft and bevel being employed. The crankshaft is of the two bearing variety with ball bearings, and there are two camshafts on opposite sides of the cylinders, which are T-headed. The magneto is of the usual car type with the distributor incorporated. The wheelbase of the machine is not excessive, but if the magneto had been placed at the side of the engine it could easily have been made 5 in. shorter, thus bringing it down to the average 6-hp. Vee twin-cylinder engine, namely, 56 in.

The lubrication system, which is also worthy of mention,

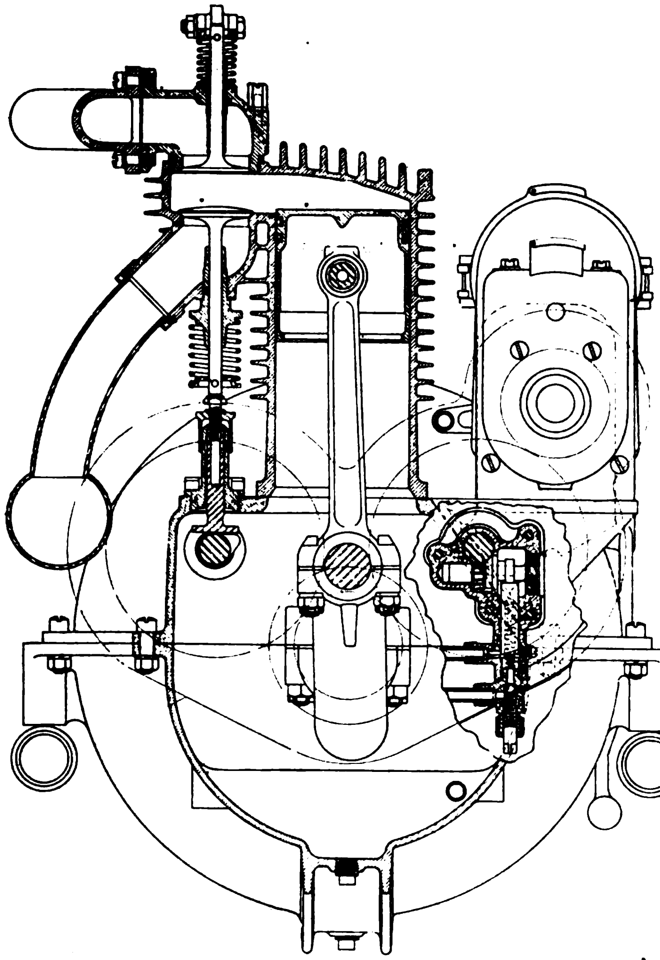

Fig. 6—Cross section of Henderson engine, showing lubrication features

consists of a special type of gear pump driven from the front end of the inlet camshaft; it draws oil from the sump and delivers it to troughs under the connecting-rods; these troughs are pressed in one with the filter plate, and the surplus oil runs through to be used over again.

As an indication of the extreme care which has been used in the construction of this engine, it should be noted that wherever studs have been employed on the crankcase they are not screwed into the aluminum, but into large steel bushes which are screwed in and pinned to prevent them from rotating.

Figs. 5 and 6 show the four-cylinder Henderson power plant. This represents another type of design, as the engine, clutch and gearbox are built as a single unit, and the drive is taken from the end of a cross shaft by a single roller chain to the rear wheel. The bore and stroke of the engine are 2¾ in. and 3 in. (63.8 mm. and 76 mm.) respectively, which give 1170 c.c. cylinder capacity. An L-head cylinder is used with the exhaust at the side and an overhead inlet valve operated by a rocker and push rod. Lubrication is automatic by means of a pump, and plain bearings are used throughout.

It will be noted that this engine also closely follows car practice and all its parts are of ample proportions and straightforward design.

As a further proof that a four-cylinder engine is not unduly long, it should be mentioned that although 28 in. by 3 in. wheels are used, the wheelbase is only 59 in.

Summary

To sum up the conclusions arrived at, we see that our requirements are fulfilled in the largest measure, and about equally, by the flat twin and four-cylinder engines. The flat twin engine has certain advantages in the way of fewer working parts, but, as generally placed, the cooling of the back cylinder is very inefficient and the cylinder is also inaccessible; in fact it cannot be removed without taking the engine out of the frame. It is noteworthy that at present there are no air-cooled flat twins in use of over 750 c.c. cylinder capacity. There is no reason, however, why below this size the engine cannot be placed transversely across the frame as has already been done by one maker, though the engine in this case is very much smaller. While a fairly large engine would certainly present a difficulty for solo use when placed in this manner, for the side-car machine there are no objections and many advantages, as it solves the cooling difficulty and also the question of accessibility; then, too, the crankshaft is in the right position for employing a proper car type of clutch and gearbox with final drive by a shaft. In order to keep the engine short, it is necessary for the stroke to be less than the bore, and as a 750 c.c. flat twin engine can easily be made less than 20 in. overall, it will go in the width of a side-car machine, many of which are 21 in. wide over the footboards. In larger sizes the overall dimensions of the engine begin to present difficulties, and we then come into the sphere of the four-cylinder engine. The even crank effort of this type is of great importance to the comfort of the rider and also in permitting the use of a light and durable transmission system, which also follows naturally from the disposition of the engine in the frame. The engine is also very adaptable to correct frame design, as it can easily be carried by a duplex tubular construction or a channel or pressed cradle when they develop.

Determining Correct Location of Brake Levers

Brakes Generally Not to Blame for Pedal Motion Due to Torque and Spring Action

By Walter C. Baker*

BECAUSE manufacturers using brakes which have proven entirely satisfactory in times past have altered their design from one using a torque member to one employing the Hotchkiss drive, and have experienced trouble in braking action, blaming it on the brakes, it has been necessary to devise some means of demonstrating that the trouble actually was not in the brakes themselves but in the manner in which these brakes were hitched up. Not only has this trouble occurred when the change was made to the Hotchkiss drive, but when the spring in this case was moved from a position above the axle to one below, many times causing engineers to say the brakes were inefficient.

In the discussion which follows I will attempt to show what most generally causes the trouble in braking action, and how it may be remedied by simply changing the rods and their locations; and it is believed that the analysis of braking action will be of great interest to all engineers connected with the design and production of automobiles.

In the design of motor vehicles employing what is known as the Hotchkiss drive, both of the passenger and commercial type, engineers have, in many cases, either failed to consider rods and levers, and braking action, or they have considered them insufficiently or incorrectly. The result has been that in a great many cases the brakes have either been inadequate or too severe. Almost universally is it true that, while at some one point and in one direction, the brakes may operate perfectly, yet at most other points or in the opposite direction the braking action is very poor.

Brake Rod Gage

Many annoying features characterize the brake that is incorrectly hitched up, in addition to the danger that always exists while driving. In all cases redesigning the brake rods and levers correctly will eliminate these disagreeable features, and to enable one to locate these centers correctly, I have designed and had constructed a brake rod gage.

It is not commonly known that somewhere in or about the rear axle there exists a transverse axis about which all torque action of the rear axle takes place. When a torque member is used, this axis is usually forced to coincide with the center of the rear wheels and axle.

When no torque member is used, as is the case with the Hotchkiss drive, this torque axis lies outside the axis of the rear wheels, and for ideal action of the brakes, the rear brake rod center should lie on this transverse torque axis, while the front brake rod center should be placed at a point which most closely approximates the center of the curve through which this torque axis moves, relative to the frame, when the car is in various positions above the axle, due to load and road conditions.

To correctly locate these points by graphical means or calculation with the information we have at present is an impossible task. They are more nearly located by tests on the car while in action, and to make such tests more productive of correct results a brake rod gage of some sort should be used.

The brake rod gage I have been using consists of several interchangeable rods, of various lengths, graduated every inch, and operating through a dial gage which indicates any lengthening or shortening of the rods, when placed by means of convenient attachments in the position of the brake rods themselves.

Action of Gage

The cause and effect of the elongation or shortening of the rods is explained in the discussion which follows.

Let us denote the torque axis by T. This is the axis

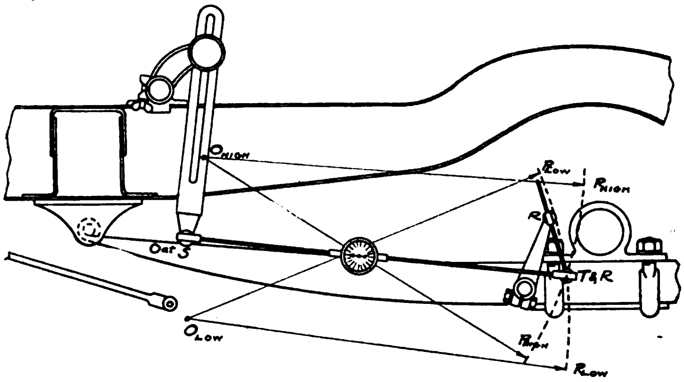

Fig. 1—Indicating conditions where O and S do not coincide

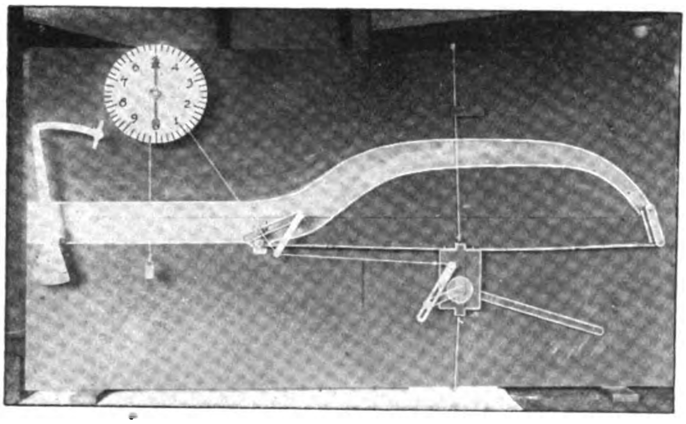

Fig. 3—View of demonstration apparatus used by Mr. Baker at Cleveland to show principles of brake layout gage

about which all torque action takes place while it in itself remains stationary, as referred to rear axle. It is plain then, that if the rear brake rod center were fixed on this axis, as far as torque is concerned, there would be practically no action of the brakes themselves due to the fact that the point of application of braking force is nearly stationary.

Let us assume, however, that the rear brake rod center is not correctly placed, and that it lies outside the torque axis on some axis such as *R*, then there must be some movement of *R* and *T* when torque action takes place.

Suppose we are looking at the car from the left-hand side, with the car traveling forward, the rear brake rod center *R* will move in a counterclockwise direction when the brakes are applied. If the rear brake rod center *R* happens to be above the torque axis *T*, such motion will tend to shorten the distance between *R* and the front brake rod center *O*. If the rear center *R* is below the torque axis *T*, the distance between *R* and front rod center *O* will tend to be greater. But since *R* and *O* are rigidly connected by a rod, *O* is forced to move with *R*, and consequently moves forward or backward, depending on the relative position of the rear rod center *R* with reference to the torque axis *T*. Of course, whatever tendency to shorten or lengthen the pull rod there may be when the car travels forward is reversed when the car travels backward and brakes applied.

With the brake rod moving forward and backward like this, one of two things must take place. Either there is a corresponding movement of the brake pedal and hand lever, multiplied by the leverage ratio, or, the brake levers of the rear axle are being operated upon independent of any voluntary action of the driver. Very often in cases of extreme movement of the rod, motion of the car in one direction automatically applies the brakes, or at least makes them grab severely, whereas, motion in the reverse direction makes it almost impossible to apply the brakes, due to the pedal in its extremes being in contact with the floorboard, thus limiting the radius action.

When the rear brake rod center *R* lies either in front of or behind the torque axis *T* on a line from the front rod center *O* to *T*, the action due to torque is usually very good, because what motion there may be is mostly up and down, which does not materially change the distance between the rear and front brake rod centers. This motion would, of course, increase as the distance of the rear center *R* from the torque axis increased, and when this became very great the change in the distance between *R* and the front center *O* would be considerable.

It is plain, then, that the only point at which there would be practically no motion of the rear axle is at the torque axis *T*, and a point on this axis is the ideal location of the brake rod center *R*.

In order to locate the torque axis *T*, let us employ the brake rod gage. The gage may be mounted either vertically or horizontally. It is shown here mounted horizontally. After the gage is mounted, a torque effort is exerted on the axle by some means. In this case, to show the action clearly, I have attached a rod to what would correspond to the axle housing, and by displacing this rod a torque effort is exerted sufficient for our purposes.

With the front center *O* of the gage rod fixed, any movement on the part of the rear center will be shown on the dial indicator, until adjustments are made which will so place this point that extreme movement in torque will have same indicator readings.

With this much having been done with the gage horizontal, it is then placed in a vertical position with the rear center still at the point just found. The locating process is then repeated. In the first case the rear brake rod center was confined to a horizontal plane containing the torque axis *T*, and in the second case, while not moving out of this horizontal plane, it is further confined to a vertical plane containing *T*. The rear center is thus forced to lie at the intersection of these two planes, or on the torque axis *T*.

We have been determining the best position for the rear brake rod center. Very often it is not possible to actually reach this point, due to the obstruction of other parts. When such is the case, the next best thing is to place it as near the actual torque center as possible and in a line with the torque center and the correct position for the front brake rod center *O* with normal load on springs. In order to do this the spring axis (*S*) must first be located, before which we must consider the action of the springs.

Car Action Due to Load and Road Conditions

When the car assumes various positions above the axle due to load and road conditions, it deflects or flattens the springs, whichever the case may be, and as they deflect or flatten the distance from the front eye to the spring seat shortens or lengthens respectively.

Since the axis of the front spring eye is held rigidly in position as regards the frame, the axle and all points on the axle member describe curves relative to the frame when successive positions are assumed on the frame above the axle. This curve that any one point describes is not an arc of a circle, because of the lengthening effect of the

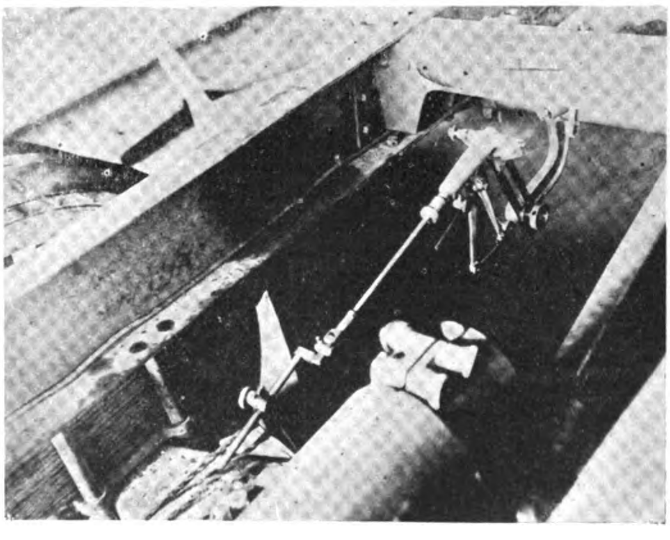

Fig. 4—Brake layout gage mounted on Class B truck

spring as it flattens. The curve is one which resembles an epicycloid, but for convenience in explanation the real curve has been exaggerated as shown here by the black line.

Since any point on the torque axis also moves in this curve, let us assume that this black line indicates the real path of the torque axis *T*. With the rear center of the brake rod *R* on the torque axis *T*, it is ideal for the front end to be at the center of a circle which most nearly approximates the curve described by *T*. This will maintain very nearly a uniform distance between the torque axis *T* and the front center *O*, and there will be practically no effort exerted to move the pedal or operate the brakes, independent of voluntary action of the driver.

If, however, the front brake rod center *O* does not lie on the spring axis *S*, we have a condition similar to the one shown in Fig. 1. Let us assume that under normal load the condition is at *T*. With the front center at *O* instead of *S*, the front center *O* will be forced to move in a circle about the countershaft a distance equal to the difference at any given position between the arc described by the torque axis and the circular arc described by the rear center about the front rod center *O* as a center. If *O* is above the spring axis or too high, a heavy load will have a tendency to loosen the brakes, making it impossible, if the front center is very high, for the operator to apply the brakes. Or often, when it is possible to set the brakes with the load on, when the load is removed the brakes will be so firmly set it will be impossible to release them. This can easily be seen from the figure. Under full load, the difference between the curves is such as to throw the front rod center forward, while at the check position in rebound the difference is such as to pull it back. When the front center is too low, as in this case, the effects are just the opposite. When a load is applied the brakes become set, and when it is removed they are loosened. Often, in such a construction, when the brakes are set and a load is put on, it becomes impossible to release the brakes without removing the load, or when it is possible to set the brakes after the load is on, when the load is removed the brakes are loose.

Incorrect Length of Rod Causes Error

Further than this, there is an error due simply to incorrect length of rod. If the front rod center *O* is behind the spring axis *S* as shown in Fig. 2, thus making the rod too short, the application of a full load has a tendency to tighten the brakes because the difference between the curves at the extreme is such that the rear center is pulled forward. When the front rod center is in front of the spring axis *S*, thus making the rod too long, the tendency is to loosen the brakes, because the difference between the curves in this case is such as to push the near center back.

Of course, there would usually be no real action upon the brakes as long as the pedal movement was unrestricted, because such errors will first be absorbed by pedal movement until the full sweep of the pedal has been reached. Designers have many times used a slotted rod or clevis to overcome this. But this movement is often so much that it is objectionable, as well as being actually a feature of reduced safety when quick and positive action of the brakes is reached.

However, the effect is much less when a rod is simply too short or too long than when *O* is too high or too low.

Now to locate the correct position of the front brake rod center *O* by means of the gage, we proceed as follows:

Assuming that the correct position of the rear brake rod center *T* has been determined, we fix it firmly by means of the necessary attachments. We then apply the load, making the frame assume various positions above the axle, or for an easier demonstration, making the axle assume various positions under the frame.

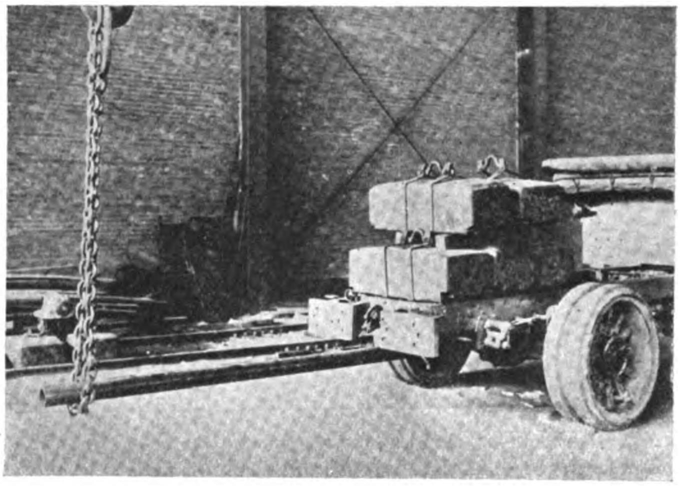

Fig. 5—Method of securing torque by chain fall and long lever on Class B truck. Note load to secure normal position of spring

The curve described by the torque axis *T* not being an arc of a circle, there are only three points which will be common to the arc through *T* at normal load about the spring axis *S* as a center. In other words, there are only three positions of the car above the axle where the brake action will be perfect, though if the front center *O* is placed at the spring axis *S*, the error at all other points will be reduced to a minimum, usually not exceeding a few thousandths of an inch, and will not be noticeable in action. For best results those points of perfect action should be chosen, first at normal load, and secondly, at points about three-fourths of the total movement of the spring either way from normal, or, in other words, the other two points should be located when the load is three-fourths the difference between normal and full load extreme position, and three-fourths the difference between normal and no-load extreme position respectively.

As the load is applied, readings are taken on the dial indicator, at the three points just mentioned, and are recorded in hundredths of an inch. When the three points have been reached, the records taken will indicate the relative position of the spring center *S* from the front brake rod center *O*.

For instance, suppose the front brake rod center *O* is too high, *O* moves in an arc about the countershaft *C*. The rear brake rod center *R* tends to move in an arc about the front center *O*, but it actually moves along the curve described by the torque axis *T* relative to the frame. Since under full load the difference between these curves is such as to push the rod forward, and since in the gage the front brake rod center is held stationary and the rod merely allowed to telescope, the change that takes place will be indicated by the dial gage readings. Under full load the rod will shorten and under no load or at check position it will lengthen.

Suppose at normal load the reading on the dial is 0.52 in. and at full load it has increased to 0.71 in. and finally at no load or check position due to the rod lengthening it has decreased to 0.36 in. Since the check position reading 0.36 in. is less than the full load reading 0.71 in., it indicates that the difference between the curves at check position was such as to pull the rod backward, and consequently shows that the front brake rod center is too high. Therefore, when the check position reading is less than the full load reading the front brake rod center is too high. From similar reasoning, if the full load read-

ing is less than the check position reading, the front brake rod center is too low. If the front brake rod center O is at the correct height the two readings will be the same, though both may be wrong for correct rod length.

If the front brake rod center O were on a circular arc described about the torque center T, and also passing through the spring center S, the rod would be of the correct length, regardless of the distance of the front center above or below the spring center, because its length would always be equal to the distance between the torque center and spring center, which is always correct for rod length. An arc about the front brake rod center O, in this case, which passed through the torque center T, under normal load, would reach just as far beyond the curve described by T at one extreme as it would fall short of it at the other. In that case the dial readings would show that the differences between each of the extreme rod lengths and the length at normal load were the same; as for instance, full load 0.67 in., normal 0.50 in., and check position 0.43 in. The differences between each of the extreme position readings and the normal readings are the same, or the sum of the extremes is equal to twice the normal. The latter method of handling the readings is the correct one, because if the rod were too short or too long but at the correct height, the difference between the extreme readings and normal reading might be the same in number of spaces passed over, but one would be a positive difference and the other a negative. This can readily be detected by simply adding the extremes and comparing the sum with twice the normal. If the sum of the extremes exceeds twice the normal the rod is too long; if less, the rod is too short.

Thus with a single set of readings we may determine our error in two directions, which enables us to make adjustments in two directions accordingly, after which we will take a second set of readings.

After the gage has been used several times it becomes an easy matter to approximate the correct amount of adjustment necessary. Usually a sufficiently correct location of the brake rod center can be accomplished in two or three readings.

When the gage was first constructed, a set of formulas was worked out which gave the correct amounts of adjustments necessary to place the front rod center at the correct position. But these formulas were rather complex and employed constants depending on the nature of the spring, and their solution usually required considerable time. After several comparative trials, it was discovered that an adjustment of the apparatus usually required less time and was more apt to be free from errors than the solution of the formulas. Consequently the formulas have been discarded in favor of simple adjustments of the apparatus, and, to further facilitate matters, easy means of adjustment have been provided on the gage.

From this one can readily understand it is not a difficult matter to have practically perfect acting brakes. When these centers are correctly located for any of the various styles or designs of chassis, one will find no further trouble with brakes due to spring action on rough roads, varying loads and Hotchkiss drive.

Testing Gasoline Content of Natural Gas

THE Bureau of Mines, Department of the Interior, has designed at its petroleum experiment station at Bartlesville, Okla., a testing apparatus for determining the gasoline content of natural gas. This apparatus is now in use and has been found to give exceedingly good results on gases containing as little gasoline as 10 gal. per 1,000,000 ft.

A valuable feature of this apparatus is that, with four compartments, the last compartment can be used as a test to see that the absorbing medium of the first three compartments has completely removed the gasoline from the gas. This is accomplished by keeping the percentage of saturation in the fourth compartment around a fraction of 1 per cent. Under such a condition an individual test can be made on the discharge gases from the first three compartments in which the saturation almost always rises to a point between 1 per cent and 11 per cent of the total volume of the liquid.

In a test made recently to determine the value of certain gas in the notoriously dry gas field of southern Kansas the apparatus checked itself consistently, proving recoverable yields from 10 gal. to 60 gal. per million.

Engineering Standardization

IN the past, engineering standardization in the United States has been confined to particular industries. The most notable example of such work is undoubtedly that carried out by the Society of Automotive Engineers, but effective work has been done also by the Electric Power Club, the Master Car Builders' Association and other organizations. As the advantages of standardization become apparent from its results on the industries by which it was adopted first, other industries are taking it up, and one of the latest associations to devote their attention to the subject is that of the gear makers.

So far there has not been in this country a body having control of engineering standardization in general and seeking to correlate the efforts of the different groups working in that line. That there is need for such a body is quite apparent. The chief reason is that each of the standards committees standardizes not only the products of its particular industry but also the raw material and semi-finished products which are used by this industry and purchased from outside sources. Now, these same raw materials and semi-finished products are used also by other industries, and if each of the industries taking up standardization should formulate its own standards for such materials, standardization, instead of a blessing, would prove a curse. A case in point is that of steel. The Society of Automotive Engineers has standardized a great many steels used in the manufacture of automobiles and other automotive apparatus. It has assigned a number to each steel, given the required chemical composition, worked out suitable heat treatments and made a beginning in tabulating the physical properties of these steels as affected by heat treatment.

Now, steel is used by all or practically all of the engineering industries, and if any considerable number should attempt to draw up standard specifications without regard to what has already been done it would lead to endless confusion. Even a change in the numbers which are used to designate certain grades of steel would be objectionable.

It is mainly because certain matters calling for standardization are of such wide import that there is need for a general standardization committee representing the entire engineering world. Such a committee, we understand, has been formed from the membership of the five great engineering societies. The actual work of standardization, the creative work, as it were, must necessarily be done by men in very close touch with the particular industry or branch of industry to which the standards apply, but there is a promising field for the general organization in supervising the work of the different branches so as to avoid overlapping of effort.

A National Automotive Body

LEGISLATION such as that which resulted in the new North Dakota law, providing that all purchasers of tractors, trucks, passenger cars and other motor-driven machinery shall have a "reasonable length of time" for inspection and testing before final acceptance, emphasizes forcibly one good reason for an active alliance of the manufacturers of all of these products—an affiliation on a truly national basis, an association comprehensively automotive. There are many other reasons equally good.

The makers of tractors, trucks and passenger cars have much in common. Their interest and well-being are linked closely together at many points. They can do much more for themselves as members of their individual industries by working together as members of a group made up of all. United action in matters of legislation, particularly, would be immeasurably more effective than individual effort. The matter of guarantees is a basic consideration which can be, and undoubtedly should be, worked out to a standard and uniform form of warranty. In patent matters, production methods, shipping, export, merchandising and many other problems which its potential members are called upon to solve, a National Automotive Chamber of Commerce could be of very great and very general benefit.

Steam for Tractor Work

IN view of past experience with steam in the automobile and traction engine fields it seems strange that there should still be such staunch adherents of this motive power as we occasionally hear from. Steam had a good chance in the automobile field and lost out. It had the traction engine field all to itself, yet according to latest reports the steam traction engine is rapidly becoming a thing of the past. In spite of these historical facts there are people who believe that if a steam vehicle or a steam tractor built in the light of the experience of the past twelve years were placed on the market, it would prove a tremendous success. The question naturally suggests itself why steam, if it has such obvious advantages as are claimed for it, did not succeed when it had all the chance in the world; but this will be met by the latter-day enthusiast with the rejoinder that its failure was not the fault of the system but of the men who sponsored it.

The strongest argument put forward by the steam champions is that regarding fuels. As long as gasoline was plentiful there was little chance of the internal-combustion engine being replaced by another type. But gasoline is becoming scarce, relatively speaking, as is shown by the rising price, and the heavier distillates, and eventually perhaps even the crude oil, must be resorted to for use as motor fuel. We know of methods of utilizing these heavy fuels in internal-combustion engines, but unfortunately engines running on such fuels are not flexible. Steam power retains its flexibility irrespective of the fuel used. The heavier petroleum fuels are subject to a number of inherent disadvantages such as dirt and ill smell. As the supply of gasoline becomes inadequate and the price in consequence rises the heavier fuels no doubt will be adopted first for commercial types of vehicles. In fact, this has happened already, in that most farm tractors are at present designed to burn kerosene. It must be admitted, however, that much of the kerosene-burning equipment put out at present handles the fuel rather unsatisfactorily. This difficulty might be overcome by burning the kerosene under steam boilers.

Old-style steam traction engines were of very heavy construction and unsuitable for use on moderate-sized farms. This objection it is proposed to overcome by entirely redesigning the power plant, basing it on automobile and similar experience. The question then would come up as to how such lightly constructed power plants would stand the heavy vibration on tractors. Inability of the piping of a steam system to stand up under severe vibration was the greatest drawback of the early steam cars. This difficulty was gradually overcome, but there is a great deal of difference between the spring-suspended passenger car frame and the rigidly supported tractor frame.

A complete change in the system of motive-power production would certainly be a radical step, but developments in the fuel situation may compel radical changes within another decade.

Road Construction

DURING the war the building of improved roads, which had received a mighty impulse in this country during the previous five years, lapsed more or less owing to the scarcity of labor and transportation and the high cost of materials. Now that the war is over there is every reason why road building should be resumed with vigor. There is no doubt that the country is prosperous. Our exports each month exceed the imports by enormous sums. Up to date our country has lent to allied Governments nearly ten billion dollars. Additional loans are being placed here by foreign Governments right along, and the money lent them does not leave the country, but is spent here for produce, raw materials and manufactured articles. Consequently the country does not lack the capital to finance road construction.

Road work would help in solving the problem of unemployment during the transition period. While eventually the industries of the country will be quite able to absorb all of the labor released by the Army, the munitions plants and the shipyards, the change from a war to a peace footing naturally takes time, and during the interval it will be difficult to find employment for all unless the Government decides on extensive construction work. The National Government has a certain moral responsibility to lighten the hardships of the transition period as much as possible, and the state governments share in this responsibility.

Many of the roads constructed previous to the war, and which have borne heavy traffic during the past two years, are in sad need of repairs. It is a known fact that a well-surfaced road, when holes once develop in it, goes to pieces very rapidly unless it receives immediate attention. During the past two years this was in many cases impossible, and many of the improved State roads have got into bad shape. These should be repaired at once.

Aside from repair work, the road-building programs of the several states that were interfered with by the war should be resumed immediately. The country has the necessary money, men and materials, and in no other way could it invest its surplus energy and its surplus wealth to such advantage as in the building of a well-constructed highway system.

Latest News of the

Protest Government Steel Price

Leaders of Industry Want Return to Supply and Demand—Alloy Steel Market Easy

DETROIT, April 22—That the Government must withdraw its minimum of $2.60 on steel in order to stabilize conditions, is the opinion of industrial leaders in the automobile field. These men feel that present prices are largely inflated, due to the establishment of the Government minimum, and that as soon as Washington allows them to get back to a supply and demand basis, business will move along far more stable lines.

Many of these industrial leaders have visited the mills and find them working far below capacity, showing that the demand is not of such a volume as would normally cause the maintenance of this high price. It is also apparent that if the price were allowed to come down to its own level, the mills would find an increase of business volume at once.

The alloy steel market is exceptionally easy, and automobile and parts manufacturers are finding no difficulty in securing quick delivery on all of the alloy steel they desire at reasonable prices. The only alloys which are causing any apprehension are the vanadium products, due to an alleged shortage of vanadium in this country. It is stated that ferro-vanadium which was stored in this country by the Vanadium Co. of America has been practically used up. It is also stated that but very little vanadium has been brought into the country during the past 2 years, on account of the lack of ships, and furthermore there has been a slip, or landslide in the valleys containing the ore producing the highest percentage of vanadium. Miners, therefore, have been compelled to use the ores containing much lower percentages until such time as the slip can be cleared away.

There is no one in the industry who feels competent to judge exactly what is going to happen to steel prices. In the first place, no one knows what Washington is going to do, and in the second place, conditions are such that all sorts of theories can be drawn from the situation, all of which sound reasonable, but are not conclusive. The opinions of leading purchasing agents in the field vary widely. There are some who even believe that the price of steel is due to take an upward rise on account of the release of heavy buying orders which have been held up during the government adjusting period.

It is believed that as soon as Washington removes its restrictions on the steel price, labor cost and living cost in the mill area will drop also. It is felt that the Government is unduly supporting labor and encouraging it in demands which prevent a firm adjustment.

Pending action by Washington, matters appear as if they were going to remain in their present uncertain state, resulting in a general tendency for buyers to use every precaution to protect themselves in advance releases.

$400,000 in First Overland Profit Share

TOLEDO, April 22—Willys-Overland employees Monday received $400,000 in checks in the company's first distribution of profits under the 50-50 profit-sharing plan announced in January. Approximately 15,000 shared in the profits, representing 9,843 at the plant here. The others are employees scattered throughout the country. The $400,000 represents 8 per cent of the wages paid during the first quarter of the year.

Maxwell-Chalmers Merger Effected

DETROIT, April 23—It is stated here by a high official of the Chalmers Motor Car Co. that the proposed merger between that company and the Maxwell Motor Car Co. has been effected. Details have not been made public. It will probably take about 10 days to work these out.

In New York, banking interests are non-committal, and in a statement given out to-day the merger is neither denied nor affirmed. The statement says: "It is true that the respective boards of directors of the Maxwell and Chalmers companies view favorably a combination of their interests, and those in control of affairs of both companies have been working toward that end, but the matter has not yet progressed sufficiently to make announcement of the details of the plan."

Rickenbacker Welcomed in Chicago

CHICAGO, April 23—Eddie Rickenbacker, spoken of by Lieut.-Col. H. M. Byllesby and George M. Graham in their welcome to America's ace of aces as "the epitome of the motor industry's effort in winning the war," was the guest of honor at a banquet to-night at the Congress Hotel, given under the auspices of the Chicago Automobile Trade Assn. About 800 men connected with the automotive trade in Chicago and the Middle West were present.

Hubbard Machine in SKF Industries

NEW YORK, April 22—The Hubbard Machine Co. will also be included in the consolidation, taking in the SKF Ball Bearing Co., the Hess-Bright Mfg. Co. and the Atlas Steel Ball Co., under the name of the SKF Industries, Inc.

Millions Being Invested in Canadian Plants

American Factory Sites Sought in Border Cities Under 6½% Preferential Tariff Lure

DETROIT, April 22—Every indication points to the establishment of scores of branch factories in Canada by United States manufacturing plants. At Windsor, Ont., it is estimated that $12,000,000 will be spent by Detroit, Toledo and Michigan companies alone. According to the Border City Chamber of Commerce, 93 big corporations are negotiating with that organization for factory sites in Windsor and its neighboring border cities.

General Motors Corp. is preparing to invest $6,000,000 in a plant at Walkerville, buildings totaling approximately $3,000,000 to be erected this year. The Maxwell-Chalmers Co. will spend $1,000,000 in new units and additions to its present plants. The Champion Spark Plug Co. proposes a $300,000 factory at Windsor, and the Auto Specialty Co., St. Joseph, Mich., contemplates a $250,000 establishment. Kelsey Wheel Co. is building additions which will nearly double present production. Motor Products Co. will soon start work on a big plant to care for Canadian trade. The Canadian Steel Corp. is progressing steadily with its $40,000,000 plant at Ojibway.

The Republic Motor Truck Co., Alma, Mich., has decided to locate its Canadian plant at London, Ont. A building site there has been selected and work on the new establishment will start immediately. During the course of erection an old munition factory will be used for the stocking of parts and possibly some assembling in a small way until the new factory is ready.

The 6½ per cent preferential tariff, which Great Britain has put in effect to assist the Dominion in expanding her export trade, is the bait drawing American manufacturers to the border cities.

This tariff supersedes the embargo on Canadian goods, giving them free access to the British Isles and all British possessions. The ruling of the British War Board, that articles assembled in Canada are to be considered Canadian goods, has reacted very favorably upon the American manufacturer, who sees in a Canadian assembly plant an open road to the British foreign market.

The movement of automotive parts makers, which is causing them to establish branches in Canada, gives the Detroit automobile manufacturer the opportunity to build his car in Canada from Canadian made parts almost complete with the exception of a few major units.

Automotive Industries

Lack of Skilled Labor in Detroit

Return of 85th Division With 3000 Skilled Mechanics Eagerly Awaited—Local Restlessness

DETROIT, April 22—There is a marked and rapidly growing labor shortage in this city and vicinity. Three months ago there were 35,000 men out of work and Detroit was wondering what to do with its returned soldiers. To-day Detroit is clamoring for the return of the 85th Division, now on its way home, and which includes nearly 3,000 of Detroit's skilled mechanics. Unskilled labor is plentiful.

The situation in neighboring towns is similar. In Flint, Jackson, Lansing and other small industrial centers in Michigan and Ohio there is a demand for skilled workers. Toolmakers are a rarity. And yet labor in this vicinity is restless. Toledo is the focal point of unrest, and has a number of strikes in various industries now in progress. Detroit also has a number of workers in various industries out, but only one prominent concern in the automobile business has been affected, and this strike has been practically broken.

Toledo Feels Effects, Too

In Toledo the workers at the Bock Bearing Co. are out, demanding higher wages and an 8-hr. working day. The workmen at the Willys-Overland Co. have presented a set of demands calling for wage increases, running up in some instances as high as 40 per cent. The demands were refused by the Overland company, which is at the present time making a thorough reclassification of its wage rates to bring them in line with what is paid at other plants in similar lines. These will be finished within a few days. In addition to this, the company made its first quarterly distribution of profits yesterday, amounting to $400,000. This had a marked steadying influence on the workmen, and it is thought that the unrest will soon blow over.

At the Wadsworth Mfg. Co., Detroit, where a great many closed Ford bodies are manufactured, 1500 automobile body builders have quit. This company refused to recognize the union and has taken practically all the heart out of the strike by to-day announcing a profit-sharing plan, with a minimum wage scale of $6 per day, patterned exactly after the Ford plan. This concern operates 8½ hr. per day, with no work Saturday afternoon. No shut-down was necessary, as the Ford Motor Co. continued operations with its own workmen.

What troubles there are are confined to the large centers. In the smaller manufacturing towns the stable element, composed of older men and men who are property owners, is in a much greater proportion. Outside agitators are not successful in the smaller towns, and there is a far greater feeling of content. Furthermore, the co-operation between municipalities and labor is much closer, because in the smaller towns the manufacturing element has a greater control of the city's affairs. The result is that matters are conducted along lines which are of the greatest advantage to the workmen. An example of this is shown in the case of Flint, where co-operation with the merchants and manufacturers resulted in a 15 per cent decrease in the average living cost.

It is the younger element which is at the bottom of most of the trouble, and the returned soldier is not idle either. Hundreds of young men who, while single, lived very well on their wages, married immediately upon their return from service. They have gone back into the shops, and while their pay-checks are somewhat larger than before the war, the extra expense of a wife and home has caused the wage problem to become one of vital importance. When a movement for increased pay is started these young men may usually be found backing the movement to the limit.

The soldier is also returning with his head full of exaggerated high-wage stories picked up overseas and in training camps. He had heard of high wages paid during the war and expects the same scale to be continued. He thinks practically every man in the shops received from $10 to $12 daily, and it is hard for him to believe that most of the high-wage stories were myths. In certain trades experts working on a piece basis did make exceptionally large wages, but such cases were but a moderate percentage.

These men apply for jobs and at the outset are disappointed with the scale. They are continually quitting and going elsewhere, hoping to better themselves. This attitude spreads to others, and as a result the labor turn-over this spring is 50 per cent more than last year. A great many of the automobile workers are joining the United Automobile, Aircraft and Vehicle Workers' Union, which is a new but strong organization and which, like a great many new organizations of this kind, seems anxious to test its strength.

Goddard Joins Militor

NEW YORK, April 24—H. A. Goddard has been appointed director of sales and advertising of the Militor Corp., New York, which last week was merged with the Knox Motors Co., Springfield, Mass. For several years Mr. Goddard was connected with the Standard Parts Co., Cleveland, as export manager and eastern representative, located in New York, and later in charge of sales for the State of Michigan, with offices in Detroit.

English Import Bars Let Down

To Permit Entry Until Sept. 1, 1919, of Five-twelfths of Automotive Apparatus Imported Between Jan. 1 and Sept. 1, 1913

NEW YORK, April 24—England has let down the bars against American automotive products. Effective immediately, the Controller of Import Restrictions will allow entry into England under license of 50 per cent of the number of motor cars, motor trucks, motorcycles and accessories imported between Jan. 1, 1913, and Sept. 1, 1913.

The restriction to this amount is to be maintained until Sept. 1, 1919, and applies also to forgings and castings for motor vehicles. Spare parts, however, are to be admitted freely under license, but only for renewal purposes and to repair such vhicles as are now in use. All imports are to be licensed in proportionate monthly quantities.

Each importer must apply for an individual import license and submit a sworn statement as to his imports during 1913. According to a cable from Consul-General Robert P. Skinner, London, the term automobiles is stated to cover motor vehicles of all kinds. Though trucks are not specifically mentioned, it is understood that they are included.

First information regarding the letting down of the bars came to the N. A. C. C. in a cable from C. C. Hanch, who is at present representing that body in England. This has since been confirmed by the Bureau of Domestic and Foreign Commerce in Washington.

Records of this bureau are not arranged by calendar years. However, the following figures will give some idea of American imports during the 1913-1914 period:

	1913		1914	
	Number	Value	Number	Value
Cars	2,783	$2,893,785	6,992	$5,615.487
Trucks	184	119,468	203	189,099
Motorcycles.	1,036	203.734	1,604	320,009
Parts	...	922,866	....	1,282,388

If the five-twelfths referred to means the months of April, May, June, July and August, then half of the sum of the two years, divided by two to give one-half year, approximately, will permit about 40 trucks and 1120 passenger cars to be imported.

Would Break Patent Licensing Plan

Locomobile Sues N. A. C. C. Over Agreement—Alleges It Hampers, Not Helps

NEW YORK, April 23.—The Locomobile Co. of America, whose president, Andrew L. Riker, was a vice-president of the National Automobile Chamber of Commerce at the time that body proposed and adopted its patent cross-licensing plan, and who is at present a member of that body's patent committee, is suing the National Automobile Chamber of Commerce for annulment of the entire cross-licensing agreement.

The importance of the suit may be judged in part by the fact that in principle it involves some 500 patents, which, since the agreement became effective Jan. 7, 1916, have been pooled by the 112 members of the association.

The suit is entirely a friendly one. The relations between the Locomobile company and the N. A. C. C. have always been entirely cordial. The Locomobile company believes, however, that the patent cross-licensing plan operates to defeat inventive genius and to "obstruct and prevent the natural development of the automobile." It is also alleged that the "inevitable effect of the agreement is actually to prevent the members of the respondent (N. A. C. C.) from making any effort toward, or incurring the expense of, developing and devising new inventions and obtaining patent protection therein, since, by so doing, the entire automobile industry is forthwith, by the terms of the agreement, given an equal right in and to the new inventions without paying any consideration therefor, not even to the extent of reimbursing the party who devised, developed and patented the invention, or any part of the cost thereof."

In further detail the complaint alleges that the arrangement tends to prevent manufacturers maintaining desirable and necessary engineering departments; that it has deterred members from developing new inventions and that in consequence of this and other charges a "great injury has been done to the automobile industry and the normal progress of the art has been interfered with, obstructed and impeded instead of being promoted as public policy requires."

The complaint alleges further that because of the situation which it outlines, the Locomobile company cannot, "with proper regard to its own interests, continue originating and experimental work and devising and working out inventions."

It is also claimed that the agreement operates as an undue and unlawful restraint upon trade and that it was "so conceived and put into effect by a few members of the respondent who conspired together to induce manufacturers of motor vehicles to execute the agreement not for the purpose as alleged therein, of avoiding patent litigation, but to secure to the respondent a virtual monopoly in and the control of the patent field of the industry, thereby increasing its power and influence therein and giving it the authority to dispose of property of incalculable value."

The Locomobile company asks in its complaint:

1—That the respondent, National Automobile Chamber of Commerce, its attorneys, counselors, officers, agents, employees and servants be enjoined from taking any steps to enforce the cross-licensing agreement referred to in the bill of complaint as against the "Locomobile" Company of America, or any other signer thereof, or from granting any licenses or taking any further action under the terms and provisions thereof, all until the further order of this Honorable Court.

2—That this Honorable Court shall order and decree that the cross-licensing agreement referred to in the bill of complaint is null and void in law, and that it be canceled and all rights acquired by any parties thereunder be restored to those parties who granted such rights under the terms of the aforesaid agreement.

3—For such other and further relief as to this Honorable Court may seem meet.

The complaint recites in detail the modus operandi of the agreement, which in brief is as follows:

The agreement was not to become effective until at least 61 manufacturing members had put into the pool at least 300 patents, and between April, 1915, and Jan. 7, 1916, this condition had been complied with and the agreement became effective on the latter date. It is to remain in force until Jan. 1, 1925.

Patents are designated "A" when they are what may be termed development patents, and "B" when they cover design "of a striking character, involving a radical departure, or a radical change, from what is known and resulting from an inventive effort of a high order, rather than a mere improvement. . . ."

Members were required to pool only their so-called "A" patents, in return for which they were given the privilege of using some 500 other "A" patents which already had been placed in the pool.

French Factory Adopts 8-Hour Day

Gnome & Rhone First to Introduce Change

PARIS, April 1—The Gnome & Rhone aviation and automobile company introduced the 8-hour day this week, with one shift. In this factory work now begins at 7:45 a. m. and finishes at 4:15 p. m., the workmen having half an hour for lunch, this time being paid them at full rates.

This is the first time a single shift 8-hour day has been tried in France. Laurent Séguin, head of the Gnome factory, concluded that there was considerable inefficiency under the 10-hour day, which began at 7 in the morning and finished at 8 at night with a 2-hour stop at midday for lunch. Under this system life was monotonous. Two of the best hours of the day were lost in eating, or in going to and returning from home. After the heavy midday meal there was at least one hour during which inefficient work was accomplished.

Before the single shift 8-hour day could be adopted it was necessary to provide dining halls for the men. Under the French factory act it is forbidden for workers to eat in the shops. Since the armistice, the Gnome company has been able to transform some of its buildings into dining halls, where men can eat without going off the premises and without any loss of time.

"Reasonable Time" to Inspect Tractors

North Dakota Law Permits Buyers to Rescind Sale on Machines "Not Satisfactory"

FARGO, N. D., April 22—Hereafter North Dakota farmers who purchase tractors are to be given a "reasonable time" in which to decide whether they are satisfactory or not.

At the last session of the North Dakota Legislature a bill was slipped through giving them this privilege, and the bill has been signed by Governor Frazier. Under the terms of the measure the purchaser is given "a reasonable time after delivery for the inspection and testing" of the machine, "and if it does not prove to be reasonably fit for the purpose for which it was purchased the purchaser may rescind the sale." Following is the complete text of the bill:

Section 1. Reasonable time to discover defects. Any person, firm or corporation purchasing any gas or oil burning tractor, gas or steam engine, harvesting or threshing machinery for their own use shall have a reasonable time after delivery for the inspection and testing of the same, and if it does not prove to be reasonably fit for the purpose for which it was purchased the purchaser may rescind the sale by giving notice within a reasonable time after the delivery to parties from whom any such machinery was purchased, or the agent negotiating the sale or made delivery of such personal property or his successor, and placing the same at the disposal of the seller.

Section 2. Provisions contrary to the preceding section void. Any provisions, any written order or contract of sale or other contract which is contrary to any of the provisions of this act is hereby declared to be against public policy and void.

Some little apprehension is felt over the indefinite language of the bill. It is thought that interpretations will be generally in favor of farmers who may be disgruntled or dissatisfied over some little thing which might ordinarily be fixed at very small expense.

Despite the possibility of remedying such slight defects, however, the bill specifically gives the farmer the right to refuse the manufacturer the privilege of making them. Tractor men feel that they face a serious situation.

As a companion to this law another was passed by the same legislature and also signed by the Governor which provides that manufacturers selling tractors in North Dakota must maintain at least one supply depot within the State and keep in it a full and complete stock of repairs. Following is the text of the measure:

Section 1. On and after the taking effect of this act it shall be unlawful for the manufacturers of any gas or oil burning tractors, steam or gas engines, harvesting and threshing machinery, automobiles and auto trucks to sell or deliver within this state any such gas or oil burning tractor, steam or gas engine harvesting and threshing machinery, automobile or auto trucks without having first established at least one supply depot within the state where shall be kept constantly on hand a full and complete supply of repairs for the same.

Any manufacturer selling or delivering or causing to be sold or delivered any such machinery in violation of this act shall be deemed guilty of a misdemeanor, and upon conviction thereof, shall be fined not less than $25 and not to exceed $200 for each offense.

Legal Standards for Gasoline Proposed in California

Three Bills Now Before State Legislature Fixing Standard Specifications for Fuel and Lubricants and Providing for Inspection and Analysis Are Opposed by Automotive Trade and Oil Producers

SACRAMENTO, April 17—Three separate efforts to standardize gasoline specifications by legislation are represented by as many different bills now before the California State Legislature. These bills seek to define gasoline and fix a standard of quality. One of them also defines distillate, fixes a standard for this product and provides for its coloring "in a manner sufficient to show clearly if one part of same is added to seven parts of gasoline." The third bill is entitled "an act to prevent the manufacture, sale or compounding of adulterated or misbranded gasoline, benzine, naphtha, lubricating oils and greases, etc., and to regulate the traffic therein and providing for their inspection, analysis, standard grades and standard tests."

These bills are naturally meeting with the opposition of the trade in California and it is expected that they will receive due attention from the industry as a whole because of the widespread consequences which would result from misdirected attempts at legislation of this kind.

In his report on these bills, filed with the Committee on Oil Industries, G. M. Swindell, secretary of the Chamber of Mines and Oil of California, said the following:

There are three bills before the present session of the California State Legislature which propose to fix specifications for gasoline and make certain other restrictions in connection with petroleum products.

Defines Quality of Gasoline

Senate Bill 127, introduced by Charles W. Lyon of Los Angeles, provides that the standards of quality and strength for gasoline, benzine, and certain other petroleum products shall be those adopted or that may be adopted by the U. S. Bureau of Mines, with the proviso, however, relating to gasoline, that it shall have a specific gravity of 60 deg. Baumé.

Discussing the principal provisions of this proposed bill, it might be said, first, that the U. S. Bureau of Mines does not fix standards, and cannot reasonably be presumed to fix standards in the future. Furthermore, if the Bureau of Mines were to fix standards for gasoline, it is certain that the qualified technicians on the bureau's staff would not mention gravity as a controlling factor of such specifications.

The gravity test for gasoline, as every automotive engineer and practically every business man interested in the automotive industry understands, was cast into the discard long since—it being amply demonstrated as of no scientific nor practical value. It is also a well-known fact to both automotive engineers and oil refiners that, even though scientific investigation had not demonstrated the fallacy of this test, the constantly increasing demand for gasoline of the quality manufactured years ago (with no corresponding proportionate increase in gasoline-producing crude petroleum) would have made the price of that particular product prohibitive; or, with a limited supply available, the development of the automotive industry in its various branches would have been seriously hampered.

Assembly Bill 108, introduced by Assemblyman Samuel Knight of San Bernardino, merely proposes to establish a standard for gasoline of 60 deg. Baumé at 60 deg. Fahr.

Introduced by a Layman

This bill, introduced by a layman, is typical of the lack of knowledge of the average man, even the average user of gasoline, of what would constitute gasoline specifications. It is not believed at this writing that it will be given any consideration by the legislature.

Senate Bill 711, introduced by Senator W. B. Shearer, at the request of the State Superintendent of Weights and Measures, as originally introduced, is also typical of what may be expected from superficial knowledge of such a complicated subject.

As originally introduced this bill defined gasoline as "a petroleum product obtained through the distillation of crude petroleum, water white, refined and free from all impurities." Its provisions, if it had been enacted as originally prepared, would have entirely eliminated casing-head gasoline from the California markets, and during 1918 we produced over 600,000 barrels (over 25,000,000 gallons) of this product, which was scientifically blended with distillate, a refinery product, and helped take care of the enormous demand for gasoline during that year.

One of the few sensible matters in this proposed bill was that its proponents specifically set forth that gasoline should be subjected to test in accordance with the distillation method set forth in Technical Paper 166, U. S. Bureau of Mines. However, later the chemist for the Superintendent of Weights and Measures decided that he would prefer not to use any cotton on the bulb of the thermometer, as prescribed in this method of testing, and proposed to incorporate an amendment eliminating its use.

It was originally planned to contest the passage of this bill because of its inconsistencies and incongruities; also because of the lack of knowledge of the situation shown by its proponents. However, better counsel prevailed, and after a number of conferences with the Superintendent of Weights and Measures, he was finally persuaded to amend the proposed bill in some particulars, substituting the so-called "navy specifications" with a 428 deg. end point for those he proposed. He at first "stood pat" on his definition of gasoline, but at to-day's writing he is convinced of the inadvisability of eliminating casing-head gasoline as a part of the available supply, and has intimated, somewhat reluctantly, that he will submit an amendment with that idea in view.

The chemist for the superintendent has also agreed to a specification of 10 milligrams of cotton on the bulb of the thermometer.

Bill Rewritten

The bill as originally proposed has been practically rewritten, and is now under consideration by the committee of the California state senate, in its amended form. As amended, after the several conferences with the superintendent of weights and measures, we have a reasonably logical bill against which we can present arguments and have eliminated its ridiculous features.

There are certain broad aspects connected with this question of fixing specifications in which both automotive engineers, the automotive industry and the oil refining industry are interested.

The particular problem confronting the oil industry to-day is one of utilization of petroleum and its products to the best possible advantage, consistent with the laws of supply and demand, and having in mind a desire to maintain reasonable and uniform prices to the consumer.

The principal outstanding fact for consideration is the production in California of gasoline-producing crude petroleum. Gasoline is not made from crude petroleum, but is extracted from it. No cracking processes have yet been developed to handle our asphalt-base crude oil, though thousands of dollars are being spent monthly by the California refiners to perfect such processes. It will be conceded, in the light of production figures which I will give you, that the development of such processes will aid materially in the solution of our problem, and may even permit California refiners to help the Middle West and East.

We produced in California in 1918 in excess of 100,000,000 barrels of crude petroleum.

Of this production, approximately 50 per cent has no extractable gasoline content, and was burned as fuel under the locomotive and industrial boilers of the territory we serve.

According to statistics compiled by the Pacific Coast Petroleum Administrator, operating under the U. S. Fuel Administration, our total production of gasoline in 1918 was 7,000,000 barrels.

This production was made up of 6,400,000 barrels from refineries and 600,000 barrels of casing-head gasoline.

It has been the custom of California refiners to accumulate appreciable stocks of gasoline during the winter months, to enable them to care for the demand when the "peak-load" arrives, during the months from June to November.

Our production for 1917 was 5,700,000 barrels, and on Jan. 1, 1918, we had in stocks on hand 813,443 barrels. However, notwithstanding a production of 7,000,000 barrels in 1918, an increase over 1917 of 1,300,000 barrels (with no corresponding proportionate increase in gasoline-producing crude), we only had available on Jan. 1, 1919, in stocks on hand, 573,372 barrels.

And this situation developed during a period when every effort was made to curtail the use of gasoline and eliminate its waste. Furthermore, this stock on hands of the large refining companies, and our small refineries, notably in the southern part of this state, are operating to-day on a day-to-day basis in supplying their trade, and have been unable to accumulate any stocks to care for the certain increased demand to come in summer.

In California, with a constant decrease of stocks on hand; an enormous increase in the price of gasoline-producing crudes; with a 24-gravity oil selling at $1.30 per barrel at the well; facing a yearly increase in consumption of between 20 and 30 per cent; and with no immediate indication of any increase in gasoline-producing crude production, we are face to face with a problem which requires the most careful and serious consideration when one considers the fixing of gasoline specifications to endure for a period of two years.

If the proposed specifications were contained in a city ordinance, there would be little or no criticism. City ordinances can be promptly corrected to meet changed conditions, but a state law remains in effect for a period of two years, and must be subject to continual and deliberate violation, or the users of the product in that state must be deprived and shipments made to localities lacking onerous restrictions, or those with which it is impossible to comply.

A Problem for Business Man and Engineer

This is a mutual business problem, not legislative, and must be solved by representatives of the automotive and oil industries. The refiners can only furnish the automotive industry with the extractable gasoline in the crude produced; and automotive engineers must provide power-producing engines which will use to advantage the power product available. The question is really one of securing thermal efficiency, and it is to this feature of the problem that automotive engineers must direct their attention.

The pressure upon the oil industry, both the production and refining departments, of the demands from the automotive industry, has caused a material change in the supply of motor fuel, and there is a real danger of reaction to the disadvantage of the consumer.

It is obvious that when you fix by law the quality of a product, you must of necessity automatically regulate the price of that commodity, provided the supply and demand continue uniform; but should the supply decrease, or should the supply remain normal and the demand increase, it necessarily follows that some one must be deprived of the product, or more naturally, that the constantly increasing demand will force higher prices for the available product.

Exports of Cars, Trucks and Parts by Countries for February, 1919

This table supplements the one which appeared in the March 27 issue of AUTOMOTIVE INDUSTRIES, *and gives figures for all of the individual countries, including those generally grouped under the collective heading "Other Countries."*

Foreign Trade Boom Continues

WASHINGTON, April 19—Exports and imports for March continue to show a large increase as compared with previous months, according to figures received by the Bureau of Foreign and Domestic Commerce. Exports for March totaled $605,000,000 as compared with $508,000,000 in February and $523,000,000 in March, 1918.

For the 9 months ended March, 1919, exports totaled $4,991,000,000, an increase of $600,000,000 over the corresponding period last year. Imports for March totaled $268,000,000 as against $235,000,000 in February and $242,000,000 for March, 1918.

Government Opposes Gasoline Combine in Trinidad

WASHINGTON, April 19.—The government of Trinidad, British West Indies, has taken steps against a gasoline combine by which prices of gasoline have been increased to 48 cents per gal. The consumption of gasoline in Trinidad is 360,000 gal. a year, used chiefly for automobiles, and up to two years ago local dealers buying their supplies from the United States, paid 28 to 34 cents per gal. About that time local oil companies formed a pool, and in order to develop and protect the local companies, the government granted them exclusive use of a government warehouse, following which the combine immediately advanced prices to 48 cents.

Evidence produced at a recent lawsuit proved that gasoline sold locally for 48 cents cost only 18 cents, with an excise tax of 6 cents, making a total of 24

cents. The Trinidad government has given the local companies 30 days' notice to discontinue storage of gasoline in the government warehouse, and has invited storage of American gasoline. This offer will be accepted as soon as shipping rates, which are now prohibitive, are reduced.

Can Ship to Leeward Islands

WASHINGTON, April 19—Exporters in the United States can now ship into the British Leeward Islands, all prohibitions against importations having been removed on all commodities.

Can Ship Tractors to Tunis

WASHINGTON, April 19. — Farm tractors, parts and accessories can now be shipped freely without import licenses to Tunis.

Exports of Automobile Tires, by Countries, During February, 1919

Rubber Imports Again Double

28,223 Tons Twice February Figures—Highest March Record in Years

NEW YORK, April 18—Rubber imports for March reached a figure not attained by any single month in the past four years. The 28,223 tons of crude rubber brought in last month more than doubled the 14,079 tons for February, and as compared with 17,161 tons for March, 1918, showed an advance of 11,062 tons.

The Rubber Association of America has compiled the following list of importation figures for crude rubber for the past four years:

	1916 Tons	1917 Tons	1918 Tons	1919 Tons
January	9,162	12,788	16,084	7,235
February	1,597	10,162	13,108	14,079
March	10,070	18,624	17,161	28,223

John Simmons Adds Truck Export Line

DETROIT, April 21—The John Simmons Co., New York, which exports hardware, machinery, plumbing supplies and other similar lines, is establishing a truck division and proposes not only to export motor tucks but to act as truck distributer in the New England States. Last year the company took over the export sales of the Nelson Truck Co., Saginaw, and the experiment was so successful, especially in the Latin-American countries, that this year it is going into the truck business on a large scale.

The Simmons Co. has just signed with the Nelson Co. to handle its distribution in all New England States, New York, eastern Pennsylvania and the northern half of New Jersey. Its export territory includes central and southern Europe, all of Asia, British Isles, Norway, Sweden, Denmark, Mexico and eastern South America.

G. E. Lyons has been made sales manager of the truck division. He was formerly with the eastern office of the Garford Truck Co. Hoyt Spelman will have charge of the export department. He has been connected with the export department of the Simmons Co. for a number of years.

The Simmons Co. will start immediately to build a warehouse on Long Island. It will be 80 x 100, constructed of concrete, steel and brick.

Exports of Tractor Engines During February, 1919

Countries	Number	Value
France	561	$768,915

1135 Tractors Sold by Canada at Purchase Price

OTTAWA, ONT., April 19—In 1918 1135 farm tractors were purchased by the Canadian Food Board of the Department of Agriculture. The price paid was $750 f.o.b. Dearborn. No duty was paid. The retail price to farmers in Ontario, Quebec, Nova Scotia, New Brunswick, P. E. I., British Columbia, was $750 f.o.b. Dearborn. The price to farmers in Manitoba, Saskatchewan, Alberta, was $795 f.o.b. point of delivery. They have all been sold.

Conference on Weights and Measures

WASHINGTON, April 19.—A conference on weights and measures will be held here at the Bureau of Standards May 21-24. Officials are being invited from the various states, together with representatives of industry, and the discussions will relate to the present independent State legislation on weights and measures, the possibilities of changing present standards, etc.

British Manufacturers Striving for Greater Permanence in Magnetos

LONDON, April 8—Though claims are being made for the superiority of British magnetos over the former Bosch machines, engine manufacturers are not entirely agreed upon this in that the average performance of the British-made magneto is not so high as it should be. The trouble lies apparently in the magneto lacking the required ratio of permanence of coercivity in the magnets. There is a strict ratio between these two necessary, and it is in this direction that the British magneto specialists are making special efforts.

One of the points investigated is the substitution of chromium steel for tungsten steel. Bar magnets of chromium steel, stored for a year without being exposed to any disturbance, kept their magnetic moment constant within 0.3 per cent and less. In all the cases the changes observed were within the limits of the experimental error in the second half of the year.

As regards constancy to heat variations, concussions and temperature coefficient, the chromium steel proved equal to tungsten steel, but in respect of coercive force and permanence the best chromium steel did not come up to the best tungsten steel. The temperature coefficient of the magnetic moment diminishes with increasing content of dissolved carbon and was found to be zero in a 1.4 per cent carbon steel.

To investigate the suitable ratio of length to diameter in the case of bar magnets, a chromium steel originally 22 cm. long and 0.6 cm. in diameter was gradually shortened to a length of 2.4 cm. This shortening raised the temperature coefficient from 2.4 per cent up to 4.2 per cent. The ratio of length to diameter, *l/d*, was also found not to be without influence on magnetometer determination of the coercive force. When the value of *l/d* fell below 10, these determinations gave too low values.

—

American Automobiles Dominate in Dutch East Indies

WASHINGTON, April 21—The American automobile dominates the markets of the Dutch East Indies and will probably continue to do so, according to Consul A. E. Carleton, who reports that there are 12,000 cars in use in the country, and that since 1915 practically nearly all imported and sold have been of American manufacture. Previously Italian and French cars were popular. Imports in the last three years have averaged 2500 cars per year.

Special requirements for automobiles in the Dutch East Indies, which should be considered by American manufacturers, according to Consul Carleton, are an adequate cooling system, as the climate is tropical; a powerful flexible engine, because of the numerous hills and long distances, and powerful springs, because of the rough roads. Manufacturers will also do well to give more thought to the details and finish of both engines and bodies.

The truck market is comparatively undeveloped. There are only 200 in the country. Motorcycles are quite common in Batavia and Weltevreden. Government construction of highways has just been undertaken in Java, and numerous roads are being built.

—

Men Needed for Air Service

WASHINGTON, April 21—The Air Service of the United States Army is in need of mechanics, including airplane, airplane engine, bench and radio makers, tool makers, metal workers and coppersmiths, balloon and airplane fabric workers, cabinet makers and balloon riggers. Enlistment in the Air Service offers advantages to the skilled mechanics, who in a majority of cases are given non-commissioned officerships. Enlistment can be made for one year if a man has had previous experience in the Air Service. Enlisted men can also learn to fly if they are physically fit and have sufficient mechanical knowledge.

—

Perfex Radiator Makes Statement of Financial Condition

RACINE, WIS., April 19.—The Perfex Radiator Co., which on March 28 was made defendant in involuntary bankruptcy proceedings in the Federal court at Milwaukee, has filed schedules showing assets of $1,248,506, and liabilities of $227,319.

Wages in Industry Decrease 8.6 Per Cent

WASHINGTON, April 21—A decrease is notable in the wages paid in the automobile industry in comparison with the months of December, 1918, and January, 1919. A decrease is also apparent in numbers employed. During the month of January, 1919, 50 car makers employed 117,844 workers, as compared with 124,902 in December, 1918, a decrease of 5.7 per cent, while at the same time the wages for January, 1919, totaled $3,041,762, as compared with $3,329,139 in December, 1918, a decrease of 8.6 per cent.

Similarly, a decrease of wages greater than the decrease of workers is reported by other industries, such as car building, boots and shoes, cotton finishing, iron and steel and paper manufacture. The iron and steel industry, for example, laid off 1.6 per cent of its workers and at the same time decreased its wages 5.1 per cent.

—

New Company to Make All-Steel Wheels

KENOSHA, WIS., April 21.—The Kenosha Wheel & Axle Co. is being organized with an authorized capital stock of $550,000 as a development of the Whitcomb Tool & Machine Co. The new company will specialize in internal spur-gear drive axles and a new type of all-steel wheel for commercial cars. James A. Whitcomb, proprietor of the old concern, will be president and manager of the new company. For the present the Whitcomb shops will serve as a factory, but a site is being purchased whereon to build a complete new manufacturing group.

—

Fulton Stock Not to Be Sold in Michigan

DETROIT, April 22—The Michigan Security Commission has refused permission to the Fulton Motor Truck Co., Farmingdale, L. I., to sell its stock in Michigan. The stock has not been approved by the commission, which threatens to bring suit against Torrey & Co., Inc., New York brokers, who have just started a sales campaign here.

—

Refined Dixie Flyer for $1,365

LOUISVILLE, KY., April 21.—The Kentucky Wagon Mfg. Co. has brought out a refined model of its Dixie Flyer, which is to sell for $1,365, with either touring or roadster body. Among the improvements are the use of a slightly larger engine with forced feed lubrication and a hot-spot manifold; fan driven from the generator shaft; larger universals; improved brake and clutch pedals; Bower roller bearings in all wheels; oil cups instead of grease cups. The external appearance of the car has been considerably improved through the use of a straight-line body with square type radiator.

The engine is a four-cylinder Spillman, driving through a Borg & Beck clutch to a Grant-Lees three-speed gearset, and floating axle. The engine is equipped with a Dyneto two-unit electric lighting and starting system, with a Bendix gear. The ignition system is Connecticut. The wheelbase is 112 in., and tires are 32 x 4. Equipment includes an eight-day clock, Motor-Meter, and the usual tools.

—

Briscoe Up to 75 a Day

JACKSON, MICH., April 17—The Briscoe Motor Corp. turned out 50 cars daily during March. This figure has been increased to 75 this month. New contracts during the past few days have been received from Brooks Motor Co., Baltimore; the Kline Motor Co., Louisville, Ky., and the Briscoe-Syracuse Sales Co., Syracuse, N. Y.

—

Eccolene Increases Capital

DETROIT, April 19.—The Eccolene Mfg. Co., maker of Eccolene, has increased its capitalization from $10,000 to $500,000. Plans call for the sale of $300,000 of common stock and $200,000 of preferred 7 per cent accumulative stock. An advertising and sales campaign will be started soon.

—

Combination Truck-Tractor on Market

CHICAGO, April 21—A new type of combined industrial truck and tractor is being marketed by the Clark Tructractor Co., Chicago. It is a three-wheel, gasoline-driven vehicle for industrial purposes in and around factories and other large organizations. It is equipped with a 4-cylinder, 3⅛ x 4½ engine, dry-disk clutch, three-speed selective gearset, internal-gear drive, and may be fitted with either cargo or dump body or platform. The machine weighs 2050 lb. and has a capacity of 1½ tons. The wheelbase is 72 in.; tread, 35½ in., and the overall length, 112 in. It will operate at from ¼ to 15 m.p.h. The selling price is $1135.

—

Graham Trailer for $400

EVANSVILLE, IND., April 21—Graham Brothers have placed on the market a 2-ton four-wheel trailer to sell at $400. It is equipped with Hess axles, with the wheels mounted on Bock roller bearings. Springs are semi-elliptic and wheels carry 32 x 3½ pressed-on solid tires. The loading space is 118 x 59 in.; side racks are 22 in. high. The three side and end sections are removable.

—

Schwartz Buys Emil Grossman Business

NEW YORK, April 18—L. M. Schwartz, formerly vice-president and sales manager of the Emil Grossman Mfg. Corp., has purchased the right, title and goodwill in that company and with it has acquired the trademark "Ever Good" identified with the Grossman lines of bumpers, mirrors, fan belts, wiring sets, etc., and also the trademark "Red Rib," designating lines of ignition cable and lamp cord. Schwartz's activities commence immediately under the former trade name (the Emil Grossman Mfg. Co.) and at the same address, Bush Terminal, Brooklyn, N. Y.

Latin America Offers Opportunities

January and February Automotive Exports Indicate Great Increase in 1919 Trade

NEW YORK, April 19—During the twelve months ending December 31, 1918, our exports of cars, trucks and parts to the Latin-American Republics had a total value of $18,976,637. The value of our exports during January and February, 1919, was $4,141,479. Throughout these periods we have had to face troubles and delays caused by severely limited shipping facilities and by restricted factory production.

If it be assumed that both these adverse conditions are factors which will have to be contended with during the remainder of the present year—an assumption which is absolutely against the weight of evidence—and that we are merely able to maintain the pace set by our January and February export figures, we still will be approximately 30 per cent ahead of our 1918 total at the end of the calendar year 1919.

Three months ago the Shipping Board allocated 455 vessels having a combined capacity of over 1,000,000 tons to Latin-American routes, but unfortunately had to withdraw them immediately in order to divert their tonnage to relieving the European food shortage.

When this need ceases to exist, it is anticipated that all these ships will operate in Latin-American service. Their capacity will be supplemented by that of a series of 12,000-ton freighters and yet a further series of converted transports of an individual capacity of from 8,000 to 15,000 tons, a service amply sufficient to link up our ports with those of Central and South America on a basis which will eliminate delay and insure prompt shipment.

There is no lack of orders for shipment of automotive products to Latin America, and given adequate shipping facilities there is no reason why the 30 per cent increase now indicated may not be expanded to 100 per cent or more.

Exports of Cars, Trucks and Parts to Latin-American Republics During the Calendar Year 1918

Country	Cars No.	Cars Value	Trucks No.	Trucks Value	Parts Value

Trade Resumed with Many Countries

WASHINGTON, April 21—A complete list of certain countries in Europe with which trade was prohibited during the war and with which business can now be resumed has been made public by the War Trade Board as follows:

Siberia,
Alsace-Lorraine,
Palestine,
Mesopotamia,
Serbia and Rumania,
Finland,
Szecho-Slovakia,
Bulgaria,
Turkey and Black Sea ports,
German Colonies,
The occupied territory of Germany,
Adriatic ports,
Albania and Montenegro,
Luxemburg,
Croatia,
Slavonia,
Bosnia,
Herzegovina,
Dalmatia,
Poland,
Esthonia,
German Austria.

Commercial Air Navigation in South Africa

WASHINGTON, April 19—South African authorities are making bids for airplanes released in England from war work, and plan to use them for commercial purposes in South Africa. Plans include the establishment of an air service, both passenger and mail, to more remote centers, and a fast mail service between Cape Town, Johannesburg, Durban and Port Elizabeth. Preparations have also begun for establishing an air route between London and Cape Town by way of Egypt. A demonstration flight will soon be made. Landing places and gasoline stations are being established between Cape Town and Broken Hill, in German East Africa and in Egypt, the landing places being 400 miles apart. The London-Cape Town route will be by way of Paris, Marseille, Rome, Crete, Alexandria and then over Africa. Handley-Page machines, capable of carrying a crew of 7 and 30 passengers, will be used. It is expected that the flight can be made in 6 days as compared with the present ocean mail service of 18 days.

Italy's Motor Service Links Up Railroads

PARIS, April 19.—Italy possesses 8700 miles of broad-track railroad and 8070 miles of automobile routes, over which a regular service is run to time-tables. This big development of automobile passenger carrying and goods service is largely explained by the fact that Italy is a mountainous country in which railroads can only be built with difficulty. Most of the main railroad lines follow the coast, leaving the center of the country undeveloped. This defect has been remedied by the creation of automobile lines which link up with the railroads.

The development of public-service cars for goods and passengers began about 10 years ago on the initiative of the Fiat Co. At the present time, of the 400 officially recognized routes, 350, with a mileage of 6950, are fed exclusively by Fiat vehicles.

Bristol Fighter	Curtiss type S
Burgess Hydroplane	Le'aviateur 8

WASHINGTON, April 19—The Air Service has classified all airplanes and engines as either "active," "obsolescent" or "obsolete," and has placed 10,414 service engines, 2612 service planes, 2643 training engines and 2103 training planes, of which 80 per cent are new, in the active class. Obsolescent engines total 10,858, of which 42 per cent are new, and 2904 training planes, of which 17 per cent are new. Obsolete engines total 2763, of which 59 per cent are new and unused, and 2018 obsolete planes, of which 51 per cent are new.

A number of Curtiss and Standard models and Bristol Fighters, about which a great storm centered during the war, besides other planes, are classified as obsolete. The Bristol Fighter, it will be remembered, was found unserviceable, because, as pointed out in AUTOMOTIVE INDUSTRIES, the American officials selected it for the Liberty engine when that engine weighed 700 lb. in its experimental stage, but was too heavy—weighing 850 lb.—when it was finally installed.

Improved Curtiss planes, the Martin Bomber, the La Pere and several British planes are named as active, as are several Hispano-Suiza engines and the Lehrone.

By active planes are meant those which are maintained, repaired and re-ordered by the government for the Air Service. Obsolescent planes are those which are not regarded as worthy of re-order, but which will be used so long as repair parts are readily available, and they can be easily overhauled until in the judgment of the officer in charge they should be discarded. Obsolete planes and engines including those found dangerous or lackin in speed or other qualities.

Herewith is the complete list, showing the active, obsolescent and obsolete planes and engines.

Herewith is the table showing number of planes and engines on hand of each of the three classes, those new and those used but in flying condition, together with those which are out of commission.

Vedrines Killed in Paris-Rome Trip

PARIS, April 21—(Special Correspondence)—Jules Vedrines, the French aviator, who was the first to make a landing on the roof of a building, was killed instantly today when his machine, on its way for a non-stop trip from Paris to Rome, dropped in the Department of Drôme at Les Fouillouses, about 225 miles from Paris. The machine, which weighed 5½ tons, was wrecked. It is thought that the accident was due to the plane collapsing in the air.

Postal Service Has 1,381 Vehicles

These Are in Use in 20 Cities—Bids Asked for Supplies and Parts

WASHINGTON, April 19—The United States Post Office is asking for bids on motor vehicle and aviation supplies to be filed not later than May 12. Supplies are required for 1433 cars and trucks, and include pneumatic non-skid casings, both fabric and cord, grey and red inner tubes of all sizes, inner patches, rims, solid, demountable and pressed-on tires, steel for demountable rims and hard base cushion tires of all sizes, fire extinguishers, hub odometers, spark plugs and porcelains of all sizes, graphite, grease, oils, automobile soap, radiators, 9000 gal. of Liberty aero oil and 175,000,000 gal. of aviation gasoline.

In order to provide information for bidders a list of the cities in which government owned motor vehicles are now being operated is given together with the number, type and size of the vehicles, as follows:

Atlanta
2 Ford, 750 lbs.
18 Commerce, 1-ton

Baltimore
15 Ford, 750 lbs.
14 Commerce, ¾-ton
4 G.M.C., 1½-tons
2 Packard, 3-tons

Boston
68 Ford, 750 lbs.
23 White, ¾-ton
14 Packard, 1½-tons

Brooklyn
71 Ford, 750 lbs.
20 White, ¾-ton
5 White, 1½-tons
5 White, 3-tons

Buffalo
25 Ford, 750 lbs.
2 G.M.C., ¾-ton
8 Lippard-Stewart, ¾-ton
1 U. S., 1½-tons
2 Brockway, 1½-tons

Chicago
166 Ford, 750 lbs.
10 Studebaker, ½-ton
35 White, ¾-ton
62 White, 1½-tons
2 Packard, 1½-tons
20 White, 3-tons

Cincinnati
23 U. S., 1½-tons
1 White, 3-tons

Columbus
10 Ford, 750 lbs.
6 White, ¾-ton
5 Packard, 1½-tons

Detroit
37 Ford, 750 lbs.
1 Overland, ½-ton
1 Reo
5 Buicks, ¾-ton
10 Packard, 1½-tons

Indianapolis
14 Ford, 750 lbs.
4 Studebaker, ½-ton

Jersey City
3 Ford, 750 lbs.
1 White, ¾-ton

Nashville
7 Ford, 750 lbs.
4 White, ¾-ton
3 White, 1½-tons

New York
98 White, ¾-ton
10 White, 1½-tons
42 White, 3-tons
75 Packard, 1½-tons
25 Ford, 750 lbs.

Norfolk
12 Dodge, ½-ton
9 White, ¾-ton
1 White, 1½-tons

Philadelphia
68 Ford, 750 lbs.
49 White, ¾-ton
12 G.M.C., ¾-ton
9 G.M.C., 1½-tons
8 White, 1½-tons
6 White, 3-tons
2 Kelly-Springfield, 3-tons

Pittsburgh
28 Ford, 750 lbs.
30 White, ¾-ton
2 White, 1-ton
8 Packard, 1½-tons
1 White, 1½-tons

Richmond
11 G.M.C., 1½-tons

St. Louis
47 Ford, 750 lbs.
14 G.M.C., ¾-ton
3 White, ¾-ton
1 White, 1½-tons
6 G.M.C., 1½-tons

Scranton
7 Ford, 750 lbs.
4 Commerce, ¾-ton

Washington
50 Ford, 750 lbs.
11 White, ¾-ton
1 White, 1½-tons
1 G.M.C., ¾-ton
1 G.M.C., 1½-tons

Bids will be opened at 10 a. m., May 12, and prices are to be quoted on the unit of each quantity called for under each item. Deliveries must be made within 30 days after orders are placed or otherwise specified by the Government.

Eisemann Reaching Normal Production

NEW YORK, April 21—The Eisemann Magneto Co. is rapidly reaching normal production. The plant is at present operating at full capacity, with part overtime. Orders on hand will keep the plant at full capacity for some time.

England Showing Interest in Commercial Aviation

LONDON, April 21—Some conception of the hold which commercial aviation is getting on the British nation is indicated in the expected transcontinental flight and also in the displays of London business houses. The Selfridge store has recently had a big attraction in a special Handley-Paige fuselage adapted from bomb-carrying for passenger flight. It has a saloon-body accommodating 17 passengers, as well as another person in a cock-pit in the nose of the craft, a pilot and assistant pilot. The complete machine, except for the passenger accommodation, is similar to the bomber, and is fitted with two Rolls-Royce engines, each of 350 h.p. fixed between the main planes, which will drive it at about 100 m.p.h. The extreme length of the fuselage is 62 ft. 6 in., and about one-third of this is occupied by the saloon, the height of which is 6 ft. 6 in. The span of the upper main plane is 100 ft., and the height from the ground to the top of the king-post is 23 ft. The weight of the machine, fully loaded, is about 6¼ tons.

At a luncheon which followed the opening ceremony, Mr. Handley-Paige stated that a number of these machines were now ready for use, and would be put into service, carrying passengers to the Continent as soon as the Air Convention, now under consideration at Paris, is signed. A new company, he said, had been formed for the purpose, and eventually he hopes to be able to convey passengers and goods to all parts of the world.

—

First De Haviland on Exhibit

WASHINGTON, April 21—The first De Haviland 4, U. S., designed and built by the Dayton-Wright Airplane Co., has been placed on exhibition at the National Museum in this city. The plane has been used in more than 4000 flights, has been in the air 1078 hours, and traveled more than 11[illegible],000 miles. It carries full military equipment, including camera, oxygen bottles, machine guns, etc.

This is the type of airplane that was severely criticized during the war, but more than 1800 of which were delivered in France and used extensively.

—

Engine Dynamometer to Be Established

WASHINGTON, April 18—The National Advisory Committee of Aeronautics will erect an airplane engine dynamometer at Langley Field for the purpose of testing airplane engines.

—

Chicago-New York Flight in 7 Hours

NEW YORK, April 22—Capt. E. F. White, an army aviator, flew from the landing field of the Aero Club of Illinois, Ashburn Field, Chicago, to Hazelhurst Field, Mineola, L. I., in a non-stop flight lasting 6 hours and 50 minutes. Captain White left at 9:50, Central time, yesterday morning and landed here at 5:40, Eastern time, yesterday afternoon, making an average speed of 106.38 miles an hour, covering a distance of 727 miles. Express train time for the same distance is 18 hours.

The record flight was made in a De Haviland 4 biplane, equipped with a 12-cylinder Liberty engine, and was made for the most part at an altitude of 12,000 ft. In recognition of "the demonstration of the practicability of airplanes for fast transportation," the Aero Club of America will award a medal to the aviator, to be presented during the Aeronautic Convention at Atlantic City, on May 4.

—

Suspend M. A. M. A. Rule for Atlantic City Airplane Show

NEW YORK, April 21.—The Motor and Accessory Manufacturers Association rule with regard to shows was suspended insofar as the airplane exhibition at Atlantic City is concerned, at the monthly directors' meeting, so that members of the M. A. M. A. may exhibit.

—

Aero Gas for Airplanes Only

WASHINGTON, April 18—The use of high test aeronautical gasoline for any purpose other than airplane consumption has been prohibited by the Director of Air Service, who has issued an order prohibiting its use in passenger cars, trucks, motorcycles and for cleaning purposes in the army.

—

Air Service Buys Free Balloons

WASHINGTON, April 19—The Air Service has ordered 36 free balloons to be made out of the surplus kite balloon fabric. These will be used for early training of fliers and especially to instruct them in meteorological phenomena.

—

Landing Fields and Airdromes for Massachusetts

BOSTON, April 18—The Massachusetts legislature has been asked to provide suitable airdromes and landing places throughout the State in order that aviation may be developed in this territory. A bill designed to give the Highway Commission power to license aviators and also to pick out places on which to land has been introduced.

—

Inter-City Reliability Run

CHICAGO, April 14—The long-promised inter-city reliability run in which dealers and owners from Chicago, New York and other cities were to compete, seems probable of accomplishment this year, with teams from New York and Chicago as contestants. According to the plans announced Friday by the Chicago end of the contest, there will be two teams from this city, one representing the Chicago Automobile Club, and the other the Chicago Athletic Association. The date probably will be June 13 and 14, and the route will be from New York City into Massachusetts, and return to New York.

Air Service Disapproves Competition for Money

WASHINGTON, April 21.—The Air Service has refused to allow any army fliers and airplanes to compete for the Pulitzer or other trophies at the Pan-American Aeronautical exhibition which will be held at Atlantic City in May. Reasons given are that the demobilization, reorganization, Victory Loan campaign and consequent reduced personnel prevent the Air Service from taking part in this exhibition. Announcement made by Major General C. T. Menoher, Director of Air Service, also states that as an additional reason the Air Service considers it an improper use of the time of fliers and government property to compete for purses and individual prizes.

"The Air Service," stated Major General Menoher's announcement, "will give favorable consideration to any project of this sort which has for its object aerial performances without remuneration for development, charitable or co-operative purposes of an international, national, State or civic character, but must adopt as a War Department policy disapproval of any project which involves competition of air service teams or individuals with private clubs or enterprises for money or other prizes or trophies."

—

Pulitzer Trophy for Airplane Contest

NEW YORK, April 18—A Pulitzer trophy to be awarded annually for airplane competition has been offered by Ralph, Herbert and Joseph Pulitzer, Jr., according to a statement made by the Aero Club of America. The nature of the competition will be decided yearly by the Aero Club. This year it will be awarded for the longest non-stop flight from any point to Atlantic City or from Atlantic City to any other point during May, while the Aeronautic Convention is going on there. The prize will be held for a year by the winner, but must be won three times to become the permanent possession of the competitor.

—

Government Not Exempt from Revenue Tax

NEW YORK, April 7—It is likely that the Internal Revenue Bill will hold that sales of passenger cars and trucks made to the Federal government, or to the various state governments, are not exempt from the new war revenue tax. Under neither the old nor the new law are there any provisions specifically exempting the government. Under the old law, however, government purchases have been held to be exempt. Under recent interpretations of the new law, such sales apparently are not exempt. It is pointed out, however, that when dealers are approached by a state regarding the purchase of a car the dealer may pass the order along to the factory and act as a commission man, instead of taking title to the car, and then reselling it. The National Automobile Chamber of Commerce points out that under such a plan no tax will apply.

Fordson Tractor Assembly

(*Continued from page* 900)

fact, each machine can readily handle 50 per day or more if it is required, which means that, on an 8-hr. basis, 15 min. is considered ample running-in time.

The block is then put back on the track by means of the overhead carriers and the castellated nuts on the ends of the bearing cap studs are wired and locked in position. With these bearings adjusted and in place, the main work of assembling the engine is practically over, as this is the most delicate part of the job.

The engine now is ready to have its accessories and housings placed upon it. The magneto assembly is a part of the flywheel and, therefore, is handled as a sub-assembly. It is a progressive bench operation, as will be seen from Fig. 10. An angle-iron carrier is utilized, and the assembly is carried on, step by step, down the bench, as illustrated. Fig. 10 shows the work in progress, looking at it from the end when the assembly is completed. The unfinished flywheels are in a conveyor rack behind the bench. There are eight men on this job, assembling Fordson magnetos, and they assemble one every 1½ min. The finished magnetos are conveyed to the traveling rack, where they meet the engine just as it has had its field plate bolted on, as will be seen in Fig. 11. These field plates are also a sub-assembly, having the field coils mounted in place. This sub-assembly is considered a manufacturing operation and is done in the shop department.

There is but little beyond routine work left to do to the engine after it leaves this point. The oil pan is bolted in place, the head put on, manifold fitted and the carbureter and intake are bolted in place, all of these parts having been prepared and placed at convenient points along the line. The timing gear housing also is placed on the engine before it leaves this chain, having been stored in racks alongside of the track at about the proper height so that but little lifting effort is required to get it over to the tracks.

Fig. 12 shows these timing-gear housings on their rack ready to be bolted on the engine, and further down the track some of them may be seen in place. At the right of Fig. 12 may be seen how the transmission track is keeping parallel with the engine track right through. When the engine is completed and reaches the end of the track it is picked up by an overhead carrier and brought over to the beginning of the tractor assembly department, where it meets the transmission completely assembled and ready to be united with the engine assembly to form the tractor.

(*To be continued*)

Dividends Declared

Kelly-Springfield Tire Co., New York, has declared a cash dividend of $1 per share, and a stock dividend of 3 per cent on common, payable in common, on May 1 to stockholders of record April 15. Fractional shares will not be issued. Negotiable warrants which may be exchanged with other warrants aggregating in face value one share of the common stock will be issued representing fractional shares.

Packard Motor Car Co., Detroit, regular quarterly dividend of 2 per cent on common, payable April 30 to stockholders of record April 15.

Truscon Steel Co., Detroit, quarterly dividend, 4 per cent on common, payable April 15 to stockholders of record April 5.

The Willys-Overland Co., Toledo, regular quarterly dividend, 25 cents a share, payable May 1 to stockholders of record April 15.

Fisher Body Corp., Detroit, 1¾ per cent, quarterly, payable May 1 to stockholders of record April 22.

Highways Transport Committees Reorganized

WASHINGTON, April 19—The Highways Transport Committee of the Council of National Defense has been reorganized so as to include direct representation from the Office of Public Roads, of the Department of Agriculture, the Bureau of Markets of the Department of Agriculture, the Post Office Department and the Department of Commerce. The committee as reorganized comprises:

John S. Craves, of the Council of National Defense, chairman.
James I. Blakslee, fourth assistant postmaster-general.
J. M. Goodell, consulting engineer, Office of Public Roads.
James H. Collins, investigator in Market Survey, Bureau of Markets.
R. S. MacElwee, second assistant chief, Bureau Foreign and Domestic Commerce.
Charles W. Reid, executive secretary, and G. B. Clarkson.

The committee will be assisted by the Highways Transport Committee Advisory Board, comprising:

William Phelps Eno of Washington, D. C.
Prof. Arthur H. Blanchard of New York.
C. A. Musselman of Philadelphia.
Raymond Beck of Akron, Ohio.
John T. Stockton of Chicago.

Special co-operation and attention is going to be given to the short-haul problem as connected with the U. S. Railroad Administration, and rural motor express as related to interurban electric line and waterways traffic.

Explosives for Road Building

WASHINGTON, April 21—All surplus TNT and other explosives owned by the War Department and which can be used for building highways and other similar works have been turned over to the Department of the Interior. A portion of the explosives will be used for clearing lands if the soldiers' settlement bill is passed by the next Congress to allow farm lands for honorably discharged soldiers.

New Russel Internal Gear Axle

DETROIT, April 19—The Russel Motor Axle Co. will shortly commence delivery of a new internal gear drive axle for heavy duty trucks.

22 Indianapolis Racers So Far

NEW YORK, April 21—Although the entry lists are open until May 1, the Contest Board of the American Automobile Association has already received 22 official entries for the annual 500-mile Liberty Sweepstakes to be run off on the Indianapolis speedway May 31. The drivers and the special cars they will pilot are:

Driver	Car
Clifford Durant	Chevrolet special
Dorio Resta	Sunbeam

Elmer P. Shannon	Mesaba special
J. M. Reynolds	Hudson special
Wilbur D'Alene	Duesenberg special
Ray Howard	Peugeot special
Eddie Pullen	Hudson special

Films to Further Safety and Highway Development

WASHINGTON, April 21—Motion pictures will be used extensively in the United States by the government through the Visual Instruction Section of the Department of the Interior to further highways construction, highways safety and other matters of national interest. The National Automobile Chamber of Commerce has been requested to secure films from the manufacturers and furnish them to the Department of the Interior for this work. Lists of films will be compiled in the near future.

Distribution of films, it is expected, will be made through various university extension divisions and other organizations such as boards of education in the various states and communities. Films will be distributed free by the government. Motion picture machines are to be purchased by the individual community.

Electric Graphic Meter

(*Continued from page* 892)

deviation, which seems to be characteristic of the drilling operation. It may be that at this point the chip begins to clear itself; it may be that the change in power consumed is due to some characteristic of the drill spindle; or it may even be due to hardness in the iron plate at that point.

When the curve reaches point G the drill begins to pierce the bottom of the plate and the friction decreases, causing the curve to drop, until at E the drill breaks through and the curve rapidly falls off along the line F to the no-load level at G. The amount of current drawn at G indicates the frictional horsepower required to drive the machine idle.

It will be seen that it takes an average of a little less than 4 kilowatts to force the six spindles through the 1¼-in. plate.

Bradley Is Back

NEW YORK, April 22—L. M. Bradley, former manager of the Motor and Accessory Manufacturers' Association, who was obliged to leave his position about Jan. 1 and go to Daytona, Fla., because of a breakdown following influenza, has returned to New York. He has regained his health and will make his future plans public soon.

Pennybacker on Highways Work for A. A. A.

WASHINGTON, April 19—J. E. Pennybacker, director of roads, has resigned as chief of management of the United States Bureau of Public Roads to devote his energies to American Automobile Associations highway work.

Rydehn Made Superintendent of Bantam Factory

BANTAM, CONN., April 19—Stuart S. Rydehn has been appointed superintendent of the factory of the Bantam Ball Bearing Co., succeeding Edward H. Cox, who resigned.

Fred W. Thomas, formerly chief engineer for the Olympian Motors Co., Pontiac, Mich., has opened a consulting and sales office at 335 Guardian Building, Cleveland.

W. R. Eaton, formerly district sales manager of the Moon Motor Car Co., St. Louis, has resigned to become president of the Aconite Tire & Rubber Co., St. Louis.

Frank R. Farnham has been elected vice-president of the Rex W. Wadman organization. He was formrely sales and advertising counsel of Hollister-White Co.

R. A. Loftus has been made factory representative of the Hession Tiller & Tractor Corp., Buffalo. He was previously assistant sales manager of the Cleveland Tractor Co. He will immediately proceed to organize the sales force in the Eastern section of the United States.

Matt R. Korshin, who for a number of years was Eastern district sales manager for the Atterbury Car Co., Buffalo, has become Western sales manager for the Selden Truck Sales Co., Rochester, with headquarters at 2334-2336 Michigan Avenue, Chicago. He succeeds A. R. Kroh, who left to become associated with the Goodyear Tire & Rubber Co., Akron. As Western sales manager, Mr. Korshin will be in charge of the dealer organization in Illinois, Indiana, Wisconsin, Minnesota, North and South Dakota.

H. P. Schuyler, for the past five years district sales manager of the American Ever Ready Works, has resigned to become manager of the accessories department of the Northern Electric Co. of Minneapolis and Duluth.

Men of the Industry

Changes in Personnel and Position

Duplex Engine Governor Adds to Force

BROOKLYN, April 21—J. K. Cravens has been appointed sales manager of the Duplex Engine Governor Co. He was formerly connected with the Excelsior Motor & Mfg. Co., Chicago, the F. A. Ames Co., Owensboro, Ky. and more recently with the Wright-Martin Aircraft Co., New Brunswick, N. J.

George L. Ritter, who has been with the company for several years, has been promoted to assistant sales manager. J. N. Ryan, recently discharged from the Air Service as a pilot, will cover New York, New Jersey and New England. R. Weston Doherty, who, it was recently announced, would cover this territory, will not be connected with the company.

Charles G. Jerosch has been appointed manager of the export office of the Corbitt Motor Truck Co., Henderson, N. C., which has recently been opened at 66 Leonard Street, New York City.

H. S. Lyons, who for two years prior to his entry into the Aviation service had charge of the sales of C-H electric devices in the territory covered by the Chicago office of the Cutler-Hammer Mfg. Co., Milwaukee, has received his discharge and returned to the employ of the company, doing sales work in the magnetic shift department.

C. N. Bradford, for two years in charge of cost and efficiency of Briscoe Motors Corp., Jackson, has been made head of the cost and efficiency departments of the Auto Body Co., Lansing.

Edwin Denby, president of the Denby Motor Truck Co., Detroit, late major of Marines, has resumed his duties as head of his company after 18 months service.

Arthur J. Peebles, former special representative of the Goodyear Tire & Rubber Co., has been made general sales manager of the Armstrong Rubber Co., Garfield, N. J. He was former secretary of the Ohio Automobile Trade Association, and an active worker in the affairs of the old National Automobile Trade Association. The Armstrong company has recently completed a new factory and anticipates a production of 800 tires and tubes a day during the coming year.

M. T. Langlais, associated with the L. Peacock Auto Co., distributors of Service trucks in San Francisco and Oakland, died last week.

Changes in Savage Arms Management

NEW YORK, April 18—A. E. Borie has resigned as president of the Savage Arms Corp. and has been elected chairman of the board of directors. This step was taken because his multiplicity of interests in this and other companies do not permit him to devote the necessary time to the duties of that position. W. L. Wright, formerly vice-president and general manager, succeeds him as president. F. R. Phillips has been elected vice-president. F. R. Pleasanton remains general works manager and Arthur F. Hebard has been appointed general sales manager. F. R. Schaefer remains sales manager of the products manufactured at the Sharon, Pa., plant, which include frames, axles, transmissions and other parts for cars, trucks and tractors. Brockholst Mathewson will represent the company in Detroit.

These rearrangements in organization are a clear indication of the company's complete change from war to commercial basis.

W. E. Marvel of the Service Motor Truck Co., has been appointed district manager for the company in Utah, Colorado, Wyoming and parts of Mexico and Idaho.

W. C. Biddle, assistant sales manager of the Franklin Automobile Co., Syracuse, N. Y., has resigned to form the Branklin-Biddle Co., Toledo, dealers in Franklin cars. Mr. Biddle has been with the company since 1913. E. P. Johnson, a member of the sales force since 1915, will succeed him as assistant sales manager.

O. S. Tweedy, vice-president and general manager of the L. A. Young Industries, Inc., Detroit, has resigned, to take effect May 1. He was formerly with the United States Tire Co. He has not yet announced his future plans.

U. S. Rubber Elects

NEW YORK, April 22—Samuel P. Colt was elected chairman of the United States Rubber Co. at its organization meeting. Officers are: President, Charles B. Seger; vice-presidents, James B. Ford, Homer E. Sawyer, Elisha S. Williams, J. Newton Gunn, Ernest Hopkinson and W. G. Parsons; treasurer, W. H. Blackwell; comptroller, W. G. Parsons; secretary, Samuel Norris; assistant secretary and treasurer, John D. Carberry; assistant comptrollers, H. B. Hubbard and W. O. Cutter. The executive committee is composed of Chairman Samuel Colt, Vice-Chairman Lester Leland, Charles B. Seger, James B. Ford, Walter S. Ballou, and Nicholas F. Brady; and the operating council of Charles B. Seger, chairman, the vice-presidents and Theodore Whittelsey.

Auto Specialties Canadian Branch

ST. JOSEPH, April 19—The Auto Specialties Co. will build a branch factory in Windsor, Ont. It will be a duplicate of its plant here.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Republic New 8-in-1 Body

ALMA, MICH., April 19—The Republic Motor Truck Co., this city, has brought out a standard all-purpose farm body designed especially for Republic trucks for general use on the farm. There are eight complete types of bodies combined in one, all of these bodies being secured by adjustments which one man can make in a few seconds.

The body is made of kiln-dried hardwood lumber and can be used as a platform body with head board and end gate; as a platform body with extension side boards, head board and end gate; as a platform hay rack with the side boards sloping to support the hay; as a regulation wagon box with removable sides and end gate; as a combination grain, apple and potato box with two-sections, tight removable sides or as a three-section tight removable side box, or as a combination stock and basket rack box. The body can also be used as a straight cattle rack type suitable also for transporting cotton.

The body will sell for $200 in No. 2 size, 11½ ft. long, or $175 in No. 1 size, 9½ ft. long. The weight of the body is 650 lb. Larger sizes can be secured to order. The bodies are painted in the lead ready for shipping.

B. & W. to Make Radiators

CHICAGO, April 18—The B. & W. Manufacturing Co., recently organized to build radiators, is capitalized for $600,000. Its officers are: President and treasurer, Lawson W. Wright, Evanston, Ill.; vice-president, Gage P. Wright, Mitchell, S. D.; secretary, Charles H. Blenkiron, Mitchell, S. D. The officers, with J. C. Blenkiron, Frank Wright and Paul M. Young, form the board of directors.

The active management of the business will be in charge of S. D. Briggs, who has been connected with the H. S. Franklin Mfg. Co., the Buick Motor Co., Pence Automobile Co. and the Hupp Motor Car Corp. C. E. Brelsford, formerly with the Splitdorf Electric Co., will represent the company in the East, with headquarters at Detroit. R. H. Cory will handle the Western territory, with headquarters at the Chicago office. Fenton L. Howard is the engineer and Philmore F. Spery factory superintendent. The factory and offices are at 5235-5257 Ravenswood Avenue.

Production is already under way and the company reports that contracts have been closed for 40,000 radiators. F. H. S. & Co., manufacturers' agents, with offices in the Grant Park Building here, will handle the sales to jobbers.

New Plant for Copper Products

CLEVELAND, April 18—The United States Copper Products Corp. will soon be housed in a new manufacturing plant, which will be completed and in operation by May 1. The first unit is nearly finished and covers 200 x 350 ft.

Two New Jordan Bodies

CLEVELAND, April 21—The Jordan Motor Car Co. has made a number of refinements in its chassis and has brought out two new bodies, one a roadster to be styled "Playboy," and the other a touring model, to be styled "Jordan Silhouette." Both are straight-line types with slanting windshields and narrow, vertical hood louvres.

Bristol Builds Passenger Plane

WASHINGTON, April 22—The Bristol Airplane Co. of England has constructed a new passenger airplane, according to a commerce report from London. The plane has a seating capacity for 14 passengers in addition to the necessary mechanics and pilot. On its trial trip it carried 12 passengers, pilot and one mechanic, climbed 6200 ft. in 7 min. 15 sec., with an air speed of 125 m.p.h. The passenger salon is ventilated to avoid drafts.

The machine stands 20¼ ft. high and from tip to tip measures 81½ ft. It weighs 16,500 lb., the power being sufficient to lift this load to a height of at least 3 miles and at 10,000 ft. to give the airplane a speed of 113 m.p.h. The engine houses are built on the middle of the three pairs of wings. On each side there are two 410-hp. engines, the total power being 1640 hp. Flight can be maintained by any two of the four engines should the others break down.

Maibohm Will Move to Sandusky

RACINE, WIS., April 18—When its $175,000 plant is completed at Sandusky the Maibohm Motors Co. will move its entire organization to that city. The executive offices and a portion of the manufacturing end have already been moved, occupying temporary quarters in Plant No. 5. The new plant will comprise approximately 75,000 sq. ft., and is expected to be ready for occupancy in about 60 days. The site consists of 17 acres.

Saginaw to Handle G. M. Properties

SAGINAW, April 19—The Saginaw Products Co., a division of the General Motors Corp., has been organized as a holding company and will conduct the business of the Jackson-Church-Wilcox Co., the Saginaw Malleable Iron Co., and the Central Foundry Co. Articles of association have been filed showing a capitalization of $10,000 and listing as stockholders George H. Hannum, manager of local General Motors interests, Henry L. Barton and H. H. Rice, Detroit.

Details of Olds New Buildings

LANSING, April 21—The addition of five new buildings, with a combined floor space of 1,000,000 sq. ft., costing, with equipment, $4,500,000 and meaning an increase of more than 2,000 employees, is the 1919 expansion program of the Olds Motor Works. The project is a phase of the $37,000,000 expansion program of the General Motors Corp. recently announced by President W. C. Durant.

The five additional units do not include the new engine plant just completed and now in production. When this new plant reaches capacity output, it will require 800 more men. Two new axle plants will be built. Each of these will be 140 x 750. One will be built at once. The other will go up this summer.

Each unit will employ from 750 to 800 men. Both will be 1-story with a narrow second story running the entire length of the building on the east. This floor will be devoted to recreation rooms for employees, dining rooms and offices for axle department foremen and their clerical help. The axle plants will be built of brick, steel and glass. The plants will cost approximately $1,325,000 each.

Each will contain complete heat-treating departments and electrical sub-stations, equipped with transformers and switch boards controlling all machinery. The two plants will have a floor space of 267,000 sq. ft. All Oldsmobile axles will be made here as well as axles for all other General Motors passenger car units with the exception of Buick. The two units will be separated by a railroad track and each will have a loading dock 16 ft. wide.

The assembly plant will be lengthened by a 4-story addition, 91 x 600, which will give this building a total length of 1840 ft. Each floor of the extension will provide 54,600 sq. ft.

A sheet metal manufacture and enameling plant will be built. This will be 1-story, 180 x 480, with a 2-story wing, 90 x 360. It will be concrete and steel with a saw-tooth roof and cost $400,000, and its equipment $150,000. It will bring into use 155,000 sq. ft. of floor space. Under the present arrangement there is a large space left between the main assembly building and the warehouse. Before the concrete shipping docks were built last year, a track ran between the two buildings. Now that shipping has been taken care of elsewhere, the tracks have been removed and a new building to occupy this space is rapidly nearing completion. This establishment is to be 71 ft. wide by 700 ft. long and will accommodate the sewing and trimming departments. This building and new equipment which will be added to that already in use will cost $125,000.

Last year the company installed a new heating plant, which is equipped with two 500 hp. Erie City boilers with automatic stokers. This plant will now be doubled in size. This also involves additional water tanks for the sprinkler system.

In addition to the new units, the entire present Oldsmobile plant will be overhauled. A complete system of elevated electric trucks will be installed. They will be operated by storage batteries. A number of other units have been planned, but when they will be built will depend upon future business conditions.

White Machine Works Doubling Facilities

EAU CLAIRE, WIS., April 21—The A. E. White Machine Works, manufacturing automotive parts, supplies and accessories, has completed plans for erecting a 2-story, 50 x 120-ft. plant. The company is employing 50 men in night and day shifts. When the new plant is finished the force will be increased to more than 100. The line of truck and tractor appliances will be enlarged to include several new designs.

Calendar

SHOWS

May 10-17—Bristol, Va.-Tenn. Cars, Trucks, Tractors, Airplanes and Accessories. Bristol Chamber of Commerce. C. W. Roberts, Manager.

May 15-June 1—Venezuela. National Exhibit of Venezuela.

June 2-6—Hot Springs, Va. Convention, Automotive Equipment Assn., Homestead Hotel.

May—Washington, Pan-American Commercial Conference, Pan-American Union Building.

June 2—Chicago, Ill.—Natl. Gas Engine Assn. Hotel Sherman.

June 23-28—Ottawa Beach, Mich. —S. A. E. Mid-summer Meeting.

Sept. 22-24—Philadelphia, Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

Buy Parts for Army Truck Maintenance

WASHINGON, April 18.—The War Department continues to place orders for large amounts of tires, gasoline, spare parts and repair parts for the maintenance of trucks and cars in the army, both abroad and in this country. Among the contracts recently placed were orders to the Packard Motor Car Co. for parts valued at $106,584; Fisk Rubber Co., $156,777; Goodyear Tire & Rubber Co., tires and tools, at $853,000; Nash Motors Co., spare parts, at $126,000. Following is a list of contracts placed recently:

Continental Rubber Co., Erie, Pa., 3500 pr. tires at $4.20, $14,700.

Fisk Rubber Co., New York, 4833 casings, with tax, $156,777.13.

Union Oil Co., Los Angeles, 70,000 gal. gasoline at 19 cents, 3500 gal. at 18½ cents, 90,000 gal. aviation gasoline at 22 cents, 8000 gal. Liberty Aero oil at $0.445, 100 gal. trans. lubricant at 24 cents; total, $37,331.50.

Goodyear Tire & Rubber Co., 4000 tubes, $6,987.93; casings, including tax, $846,113.90.

Firestone Tire & Rubber Co., Akron, 1000 casings at $9.86 plus packing, $9,871.10; 230 tires at $32.37, $7,445.10; 8600 tubes plus packing, $14,501.32.

The Mathers Spring Co., Toledo, 170 cart front springs and 170 part rear springs, $7,553.18.

Muncie Gear Works, Muncie, Ind., repair parts to maintain 2000 military trucks, $17,671.40.

Locomobile Co. of America, Bridgeport, Conn., spare parts to maintain 1195 Riker trucks, with tax, $60,463.03.

Packard Motor Car Co., Detroit, spare parts, including tax, $106,584.41.

Premier Motor Car Corp., Indianapolis, Ind., mounting 1021 steel ammunition bodies on Nash chassis, at $17.19, $17,550.99.

Kissel Motor Car Co., Hartford, Wis., mounting 406 steel ammunition bodies on F. W. D. chassis, at $17.19, $6,979.14.

Continental Motors Corp., Muskegon, Mich., various parts, $5,411.16.

Pierce Arrow Motor Car Co., Buffalo, spare parts to maintain 1454 trucks with tax, $39,060.42.

Nash Motor Car, Kenosha, Wis., spare parts to maintain 3827 trucks, with tax, $126,232.98.

Four Wheel Drive Auto Co., Clintonville, Wis., spare parts to rebuild 150 trucks, including tax, $60,737.58; spare parts to maintain 1939 trucks, including tax, $64,825.07.

Cadillac Motor Co., Detroit, spare parts, with tax, $78,767.93.

Michigan Malleable Iron Co., Detroit, 500 sets wheels with skid hooks for 3-ton trucks, $74,392.12.

Fairmont Tool & Forging Co., Cleveland, 8000 kits tool for trucks, $31,200.

Michigan Boosts License Fees

LANSING, April 19—Car truck and motorcycle licenses in the state of Michigan may be boosted by the state legislature 10 cents per 100 lb. on passenger cars and from 15 to 25 cents per 100 lb. on all trucks, in addition to an increased tax on truck horsepower of from 15 to 25 cents. The horsepower tax on passenger cars remains unchanged.

The license increase is embodied in a substitute measure for the Evans bill. In addition to the increase in the license cost of all cars and trucks, a straight tax of 50 cents per 100 lb. is provided for all trailers. It is estimated that the revenue from the increased tax will amount to approximately $800,000 per year. The bill, it is said, will meet with little opposition in the house and senate.

Post-War Finance

(*Continued from page* 894)

Washington, their property rights abroad will be defended, if need be, scrupulously and sternly.

Another very vital post-war problem is that presented by the precarious financial condition of the railroads. Its multiple ramifications affect every phase of our business life. And the situation grows more desperate every day. During 1918 the deficit piled up under Government operation, and which is to be met out of taxation, was in excess of $200,000,000; to which has been added more than $70,000,000 during the first two months of the present calendar year. Yet rates are 25 per cent higher and the service poorer than ever. It is true that in February the gross earnings of the railroads increased $61,000,000 over the corresponding month in 1918, a gain of 21 per cent; but operating expenses, which a year ago had run close to gross revenue, increased $62,600,000, or 24 per cent. And the net operating income of the railways for February was nearly $37,000,000 less than the compensation guaranteed by the Government. In January the deficiency was $55,000,000.

Under the sympathetic management of the Railroad Administration, which recently granted a further wage advance of $65,000,000, wage increases of $910,000,000 have been allowed. During the last three years wages have increased $1,260,000,000 and have more than absorbed all additional revenues obtained from higher rates charged for freights and passenger traffic. A revolving fund of $500,000,000, which was voted to meet capital requirements, has become a dissolving fund in the face of railroad necessities. To meet the losses in operation and capital requirements of the roads, a sum aggregating more than $1,000,000,000 for the period covering Government control has already been required in Government funds to be raised from tax resources.

The country was promised, by those responsible for this debt, that vast economy in operation would be effected, which would show convincingly the wisdom of their plan. Experience has proven that the economies effected have been negligible in comparison with the expense added; and that, on the whole, less efficient service—less satisfactory to the public and less promising for future needs—has been rendered at a largely increased cost to the taxpayer.

Progressive Assembly
Fordson Tractor

THERE are two principal parts in the Fordson tractor, the engine and the large transmission housing which really takes the place of the frame. The assembly system, broadly speaking, consists of two parallel lines of conveyors, one carrying the engine block and the other the transmission housing until they are ready for bolting up on the final assembly conveyor. Beginning at the left of the plan herewith the machined parts first pass through electrically driven washing machines and then proceed to the assembly conveyors. The camshaft and crankshaft are fitted first to the engine block, after which it is run in a burning-in stand. From this point the conveyor chain is fed by overhead chutes with flywheel, fan pulley, magneto and the other parts forming the engine.*

Meanwhile the transmission housing has been picked up from the main stock conveyor and hung open end up on the first of the housing assembly chains where the gears and clutch are dropped into place. The housing is then swung into a horizontal position on to the next step of the conveyor train, where the worm and rear axle are inserted, the axle housings bolted in place by electric bolt drivers. This part and the engine block are now ready for bolting up. They are

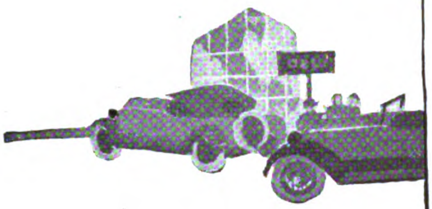
CONTINENTAL MOTORS
Powerful as the Nation
AMERICA'S STANDARD



The Most Important Question: "Has it a Red Seal Continental Motor?"

With the buyer of a motor truck or passenger car today, the time for experimentation is past—he demands a vehicle of *proved* worth.

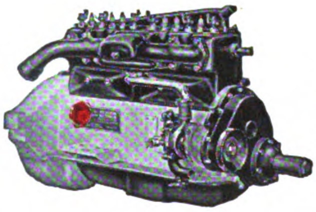
Naturally, therefore, his first thought is of the motor. And the most important question is:

"Has it a Red Seal Continental Motor?"

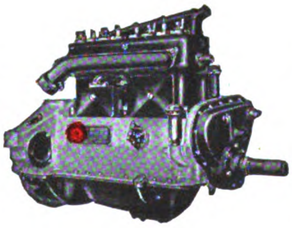
He knows that a motor which for more than a decade and a half has stood the test of service, in hundreds of thousands of automobiles and trucks, under the most exacting demands of peace and war, is a motor upon which he can absolutely depend.

The Red Seal Continental Motor has stood *this test of past performance*—in power, in speed, in economy, in all-round reliability. As a consequence, more than 160 successful manufacturers of automobiles and trucks have selected this motor—and upwards of 15,000 dealers have approved their judgment by handling Continental-motored cars. Tens of thousands of owners will have no other motor.

Look for the Red Seal on the motor in the car or truck you buy—it's your unfailing guarantee of motor dependability.



America's Standard Passenger Car Motor. Look for the Red Seal Nameplate.



America's Standard Truck Motor. Look for the Red Seal Nameplate.

Less Government Interference

Is the Demand of Foreign Trade Convention

Imperative That Ships Be Sold Soon to Americans—Cannot Look to Allies for Export Business—Best Opportunities in Latin America and Other Neutrals—Reciprocal Trade Essential

By Allen Sinsheimer

CHICAGO, April 25—Prompt sale of the American merchant marine to Americans and speedy return of the railroads to their owners are vital to the success of our export trade.

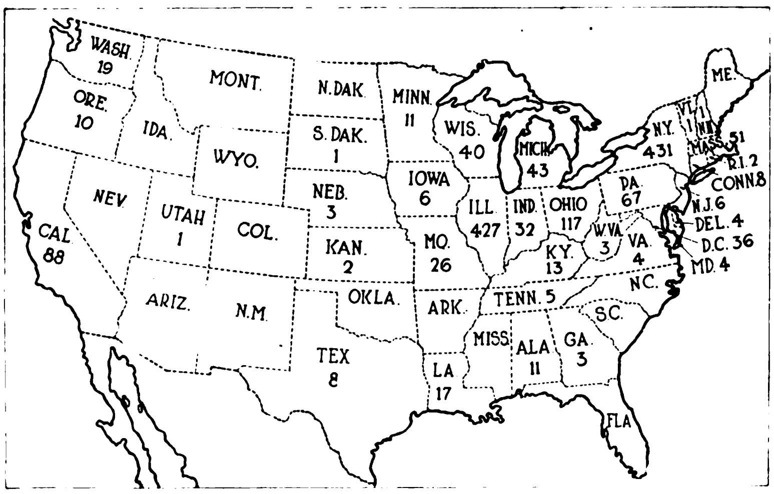
Less Government ownership and interference with industry are necessary to insure success to America's foreign commerce.

These major conclusions and a unanimous demand for a prompt statement by the Government of its policy toward industry were dominant features of the Sixth Annual Foreign Trade Convention held here this week. Widespread applause attended every demand for less Government interference in business.

That we cannot look to our Allies for export business, that we must purchase raw materials from the neutrals with whom we do an export trade, that Latin America and some of the European neutrals and the Orient will form the chief outlets for our export, that cash against document at New York is harmful practice and poor business, and that we may look to Germany for keen competition in the neutral trade are others of the most vital developments of the convention.

The Allies are not going to buy more than they absolutely have to from the United States. It would not be good business for either at this time if they did. Their policy is one of self-defense and they must buy little and sell much for the next 3 or 4 years if they are to stabilize their financial positions, and this in turn will eventually mean more speedy repayment to the United States of the outstanding war debts.

Only legitimate and stable foreign trade is built on a reciprocal basis—we must buy from those who buy from us. We must purchase raw



Number of delegates from the various States present at the National Foreign Trade Convention. In addition there were many from abroad. Almost every country in the world was represented by a delegate from its American agency

materials from those nations to whom we sell finished products. This means that they will have the cash to pay for our exports and it insures a sound exchange basis. We cannot now buy raw materials from our Allies. They need them all and more for reconstruction. We can buy raw materials from the neutrals, and it is to them in turn we must look for export business.

Latin America, Scandinavia and Norway and the Orient will all be excellent markets for American products in the opinion of the various speakers. Latin America, which has been buying from us on a greatly increased scale since the outset of the war, will undoubtedly continue in great part to import American products. In some few instances Great Britain, France and Italy may undersell us, but in the main, and particularly in the automotive field, we will undoubtedly hold our own and increase. The readiness of American automotive manufacturers to supply now and our quantity production and low prices are important factors.

The Scandinavian countries are friendly to the United States as a result of the war. The British censorship seriously affected the feeling toward her, and it was said at the convention that the Scandinavian manufacturers are looking to the United States for many commodities.

Prosperity through the war has greatly increased the buying power per capita of the Orient, and we can secure cash there for our products and in addition give credit quite freely and in safety.

These are fields that the Allies cannot well sell to for some time to come and give promise of great and successful business for the United States.

Consequently, with the debt of France so great that it is about $1,000 per capita, with Italy laboring under the burden of debt and minus natural resources of iron and coal, and with Great Britain forced to control her imports until she can well establish her exports, American industry should for the time being give up expectations of a large export business to those countries and concentrate its energies on the neutrals, and particularly those from whom we can buy raw materials for conversion to finished products.

The practice of selling for cash against document at New York means first a continuation of the gold stream that has been pouring into the United States and upsetting seriously the financial exchange, and secondly, in view of the money markets of the world and the need for us to extend long credits, it is a bad business principle to-day.

German Competition

Because the hatred of neutrals will likely be less than that of the Allies, Germany plans her first commercial onslaught toward the neutral countries, and the United States should prepare to meet German competition possibly more strenuously than the competition of the Allies.

France, as was told at the convention, is to-day in dire need of long credit. The French nation has lost $7,000,000,000 worth of buildings, $12,000,000,000 of agricultural and industrial land and facilities and almost $5,000,000,000 in other properties and cannot hope to pay off her indebtedness or pay cash for commodities for years to come. She does hope to some extent to pay for imports with raw materials, as, for example, potash, of which she has 300,000,000 tons secured by the return of Alsace-Lorraine.

German Export Trade

German export trade, it is thought, will be directed toward the neutrals and that we may look for keen competition from her. The German manufacturers fear that the hatred of German products will continue for some years to keep them out of the markets of the United States, Great Britain, Italy and France, and consequently they look to the other countries.

That all export problems and our big national problems must now enter into the consideration of every individual industry planning foreign trade, that the Webb-Pomerene Act will, without question, be the biggest single factor for development of American trade, that direct selling is the only logical method for selling abroad, that foreign advertising can be successful, but requires most careful handling, and that the shipping situation must soon be cleared up and lower shipping rates set were other important developments of the sessions.

European Neutrals' Trade

They offer our best trade areas. Neutral countries in Europe are favorable to U. S. A. trade. They have grown wealthy during the war. Their shelves are empty. Credits must be extended and cash against documents is not the best method of building up foreign trade. Exclusive selling agencies should be placed in each country.

Direct selling in export trade, discussed an entire afternoon in the convention by over 500 delegates, is the only satisfactory way to carry on export business, according to the opinions of experienced concerns. Many of the speakers who have been in export trade for 20 years have just recently returned from Europe, where they have been studying post-war conditions.

By direct selling is not meant sales to the consumer by the maker, but rather the operation of his own selling organization by a manufacturer which can be done either by:

1. Branch houses.
2. Representatives and jobbers.
3. Exclusive agents.

The manager of your export business should be an American familiar with American manufacture and business, and his staff should be native to the country in which he is located. Branch houses allow for better control of the stocks on hand, better service and cultivation of the buyer to a higher degree than through a foreign agent. Advertising, too, can be handled more advantageously through a branch house.

Where an exclusive agent is used he should be well established in the trade engaged in and loyal to the United States. Generally the longer such an agent is established the more reliable he becomes. He should be assisted when first starting by one or two men sent by the manufacturer who can aid him with sales and advertising help.

Many local problems arise in connection with direct selling. In England and France sales are often very small and good representation is very necessary. In the hardware industry sales to consumers often average $2.50, which emphasizes the need for competent representation. Selling costs in England and France are 15 per cent higher than in the United States. Direct sales in Latin America demand a thorough study of the people.

Practically a unanimous approval and optimism prevailed with regard to the Webb Act allowing combines for foreign trade, and it was stated frequently that it would be the most vital aid to building up American foreign commerce by allowing our manufacturers to combine and compete fairly with foreign trade. It was also the

general opinion, with few exceptions, that the various legal interpretations that are possible will not be used to obstruct foreign commerce and that the bill, as it stands, is of particular significance, since it is the first direct concrete and co-operative aid that our Government has extended to industry.

That our shipping bottoms will be ample to care for our foreign trade once they are safely in the hands of American owners was a universal opinion. Shipping rates, it was also said, will not be reduced until after the shipping situation is settled, and until then must continue to some extent to interfere with export trade.

Advertising abroad must be done directly by the manufacturer and not through a dealer, to secure the most successful results, and can be made most profitable if it is properly and carefully handled. Too many manufacturers have plunged either with too little or to much money into advertising campaigns in the various countries without first making a careful survey of the field and inquiring into the mental and material conditions of the people, their customs, peculiarities and systems. No two countries can be sold on the same plan of publicity. Each must be surveyed and analyzed separately. The population, buying power per capita and all local conditions must be considered.

Successful Advertising

Advertising can, however, be done most successfully if sufficient attention is given the subject and the appropriations are properly divided and expended through some advertising agency familiar with the countries in question and capable to judge the proper media.

One of the best examples of how foreign trade differs to-day from that of yesterday, and means that the export manager of an automobile factory, for example, must also consider numerous of our big national problems and many other exports that are far removed from the automobile industry, lies in the usual war condition that has set up a situation calling for special care with regard to every material and product. We will have to give consideration to every item for export separately and intensively. Thus the statements made that raw materials should be worked at home and not exported, though in the main form a sound conclusion, met with a reasonable contradiction in the discussion by Fred I. Kent, vice-president of the Bankers Trust Co., who stated that the shipments and prices of raw cotton from the United States to Great Britain will play a most important part in all of our export business to that country and in its imports to us and in our financial relations.

Great Britain, he said, will first have to control her imports until her exports are re-established. A flood of imports now against her much decreased exports will only serve to send her further lower in the financial scale and tend to make her position still more unstable. She will have to ship to the neutrals to whom she is in debt before she ships to the countries that owe her. And it will take her a long time to pay her American indebtedness, because to keep her foreign commerce alive she must buy raw cotton from us in huge quantities and at fair prices. This will continue her as a debtor nation to the United States. Great Britain must have raw cotton in order to make textiles for China, India and other countries. These offset her imports from those countries. If we do not sell her the raw cotton at normal prices Great Britain will not be able to compete abroad with her textiles, be unable to pick up her world trade rapidly and possibly ruin her foreign commerce that is now practically vital to her future. If we do sell raw cotton at fair prices to England it means that her world trade will revive rapidly, she will be able to meet her American obligations more quickly, will increase her financial income, enrich her and increase our exports to her and allow her to speedily pay off her war indebtedness to us.

Consequently in this instance it appears that the export of automobiles and the relaxation of the existing embargoes and curtailments against our automotive products is directly influenced by this problem of cotton. Sufficient cotton at fair prices will apparently mean earlier relaxation of restrictions against American automotive commodities.

France's Economic Error

France, said Mr. Kent, is making an economic error in her attempt to make all possible products within her boundaries instead of manufacturing those which her climate, geographical situation and resources best warrant. Continuance of her present course, he believes, will tend to further diminish French foreign trade because no country can manufacture for export without buying abroad for manufacture, for any length of time and do it profitably. The French indebtedness to us would be more quickly reduced if she would work to establish her reciprocal foreign trade instead of attempting only to develop export business.

The extreme importance of our various national problems in their relation to foreign trade was emphasized particularly in the matter of labor and of Government ownership. The deep feeling against continued operation of the railroads and merchant marine by the Government was evidenced frequently by the widespread applause of every statement favoring the return of the roads to their owners and the sale of ships to American concerns and individuals.

The inability of export managers to make prompt deliveries because of existing railroad conditions was stated often. The present high costs of freight transport are an important

The Webb Law

A practically unanimous optimism and approval of the Webb Law prevailed. Confidence was expressed that the bill is the most important single factor for the development of export business. Majority of opinions were that the Government will not interpret the provisions of the bill from a strictly legal viewpoint to create pitfalls for the combines organized under it unless they engage in dishonest or unfair practices. The tendency of lawyers to emphasize its legal frailties was decried.

Opportunity for Oriental Trade

The Orient, prosperous as a result of the war and untouched by the post-war problems, offers important opportunities for American export trade. We can sell for cash and we can purchase raw materials in the Orient to be manufactured into products that can be resold there. This means a stable financial condition of exchange. American manufacturers should concentrate their energies to a large extent now on the development of the Oriental trade.

Competition by the Allies

A healthy competition for foreign trade by Great Britain, France and Italy against the United States will do more to create a stable financial world condition than a widespread commercial victory by our Government. We should welcome the competition. Apathy on the part of any of the Allies should be decried. Great Britain will be probably the first to enter into a keen competition, but her entrance cannot be expected for some time.

barrier to competition with foreign firms in prices.

That the governmental policy of continuing war contracts now for the purpose of providing workers with labor and wages was proclaimed most likely being fair, but, it was stated by Homer Ferguson, president of the Newport News Shipbuilding Co., the system of maintaining the cost-plus contracts and the consequent high war wages fixed by the Government was unstable and unsound. Many of his shop workers he said had filed income taxes ranging between $5,000 and $9,000 dollars for last year and were now earning between $100 and $175 a week engaged on work that is being provided solely to keep them employed. This he and others pointed out tends to keep up our entire wage scale and consequently our selling prices and is seriously harmful to our competition in the markets abroad. It means such high prices for ships, for example, that unless a great part of the cost is at once written off, the ships cannot operate profitably and must work at a great loss even at prices far in excess of foreign scales.

Return of Ships to Private Owners

Unanimous approval was expressed for some method whereby the ships now owned by the Government would be sold to American firms at reasonable prices and on reasonable terms.

The present unstable labor condition was referred to by every speaker and practically every discussion terminated with a denunciation of the bolshevistic tendencies, now so threatening and tending to prolong the existing labor problems and consequently increasing the difficulties of export trade.

The need for governmental declaration of its future policy toward business and expression that Government interference with business should cease were statements made frequently. Edward N. Hurley, speaking at the banquet, emphatically denounced Government interference and the present tendency of many business men to seek too much Government co-operation. "Business," he said, "should not get into the habit of relying upon the Government to solve difficulties which can be overcome by ordinary business skill and honest methods." He also demanded that our Government should state its position and policy toward industry and labor clearly and promptly, and referring to the Webb Act which many lawyers speaking at the convention claimed is too full of legal complications and threatens to create a quicksand in which industry will find itself mired, he stated that "most business problems require common sense rather than legal reference and require good judgment and honesty of purpose rather than reference to the courts."

That the Webb Act is important not only as the first concrete evidence of our Government's intention to aid business, but also as a practical vehicle on which our foreign business can ride to prosperity speedily and wholesomely was the expression of the majority of business men and some lawyers present.

There is no question in the mind of the Federal Trade Commission, stated John Walsh, former chief counsel of that body, but that Congress intended the act primarily as a method to promote foreign trade, as is indicated in its title, "An Act to Promote Foreign Trade and for Other Purposes," and the Commission, he stated, does not intend to quibble over every possible legal interpretation and will insist only that our foreign business under the Webb Act will be fair and honest. The passage of the bill, he said, indicates the Government's desire to aid foreign trade development and the provision included in the bill providing that when a concern violates its intent the firm will first receive notice of such violation together with suggestions and recommendations for changing its policy or structure is itself another indication that the Government has the highest respect for American business integrity and has adopted a policy of co-operating with rather than persecuting our business world.

The Balance of Trade, and Exchange

The pound sterling, released from a fixed rate of exchange, is losing in value, and in consequence imports into Great Britain take on an added cost to the consumer. It is prophesied the pound sterling will decrease to $4. This means an 18 per cent increase at least in the selling price of American commodities in Great Britain. With the apparent sanction of the British Government to the decreased value of the pound sterling it can be assumed that this action is intended to construct a protective wall against imports to take the place of a tariff which Great Britain lacks.

Eventually this policy will stabilize exchange rates and create normal trading and finally permit a healthy American-British foreign commerce.

Our Allied Trade

We may be out of European trade for a time, but when Europe becomes normal there will be greater trade opportunities than before the war. Our Allies must control imports until they re-establish export trade. We must prepare to take European securities and buy their merchandise de luxe in return for our trade—there is something more than profit in foreign trade.

No Obstruction of Business Intended

He stated that more than 80 combines have already taken advantage of the Act and include all varieties of business. The Commission, he stated, after an exhaustive study of the bill found it was unreasonable to suppose that Congress had intended to obstruct our foreign commerce and he defined the Act as a means of promoting export trade along fair and legitimate lines and said that manufacturers following honest principles would find no Government interference because of possible legal variations.

"When the Commission," he said, "has reason to believe than an export trade association has committed an act or made an agreement which is in restraint of trade within the United States or which is in restraint of the export trade of any domestic competitor of such association or where such association has entered into any agreement or done any act in this country or elsewhere which artificially enhances or depresses prices in this country of products exported by the association or where the same substantially lessens competition in this country or otherwise restrains trade therein," which are the various restrictions of the Webb Act, "it will conduct an investigation." If it concludes that there has been a violation of the law it may make recommendations to the association for readjustment of its

business to accord with the law. "Thus for the first time in our history a penalty is not provided for violation of a law of commerce but in its stead is a recommendation for readjustment which may be acted upon by the Attorney General if not complied with. Congress evidently recognized by the passage of this provision that business men are generally anxious to maintain the highest ethics of trade, that violations are seldom international and will be promptly corrected when attention is called to them."

Import trade by a combine under the Webb Act, he stated, is not permitted. But, he said, Congress must have had in mind, when passing the bill, the many powers that are granted a corporation under its charter, and it is evident that a Webb combine can engage in the operation of wharves, warehouses, elevators, ships and many other activities incidental to its export trade. Two forms of organization are most common under the bill, one being the corporation formed of the various manufacturers each as stockholders, and the other being merely a simple agreement of a number of manufacturers to engage in export business.

A more pessimistic view was taken by L. H. Bissell of Chadbourne, Babbitt & Wallace, who stated the bill was filled with pitfalls for any combines formed under it. The problems he presented, however, he appeared to answer quite completely and satisfactorily. These were chiefly of that variety that come under the name of strictly legal interpretations. Suppose a combine, he asked, of American producers ship so much of their production abroad that they diminish the home supply, forcing up domestic prices, would not this be a violation of the Act which prohibits enhancement or depression of prices and restraint of trade? He answered this by stating that if manufacturers agreed upon a reasonable amount of their product for export prior to engaging in export trade each year there would probably be no interference by the Government regardless of the effect on price or trade at home.

Can a combination of American manufacturers undersell another American combine also under control of the Webb Act or any American exporter abroad, without interfering with the restraint of trade clause, if the foreign underselling ruins the competitors' business at home? was another question presented. It was answered that any underselling abroad would be allowed so far as it was honest and fair and based purely on production and sales costs.

That Webb combines could also sell products cheaper abroad than at home was thought permissible provided that it was done to meet foreign competition, but would not be allowed if without justification.

He also defined "foreign nations" as used in the Act to mean that the Webb concerns may sell to the Philippines but not to Hawaii, Porto Rico or Alaska, and the use of the word "navigation" he interpreted as "commerce" and allowing for both import and export business by the combines under the Act. He did not believe American manufacturers could manufacture abroad for export under the Webb combine plan but could properly assemble parts shipped from this country abroad for export sale. The combines, he also stated, could not sell materials in this country even though for manufacture here for export, but might be allowed to sell finished products to concerns in this country for export by them.

Allen Walker of the Guaranty Trust Co., who, it was stated, has organized 90 per cent of the combines now operating under the Webb Act, is very optimistic and assured that the Federal Trade Commission does not intend to restrain American manufacturers except where it becomes seriously necessary. He stated that American combines organized for export and representing similar industries, should be careful to avoid difficulties which could arise by the playing off of one combine against the other by foreign competitors. His fear of this possibility is so great that he urges the creation of single large combines to represent an industry rather than several smaller ones, and pleaded for abolition of petty jealousies between manufacturers.

The general impression gathered, however, from the various discussions marks the Webb Act as a most important aid to the development of American foreign trade, and the viewpoint taken, aside from that of a few lawyers, can be said to have been very optimistic.

The unpegging of the pound sterling and its consequent decline to $4.60, and the general unstable exchange condition, was a matter of considerable concern. Predictions were made several times that the pound sterling will likely go down to $4 and that Great Britain is planning the decline as a sort of protective measure to take the place of a tariff. The decline of the pound sterling has the effect of increasing prices of all products imported, since the importer must pay 4 per cent more (on the basis of $4.60) to the manufacturer from whom he imports. This means that the British public will pay from 4 to 10 per cent more for the commodities imported and has the effect of decreasing the imports. A decline to $4 would have the effect of raising the price paid to American manufacturers by 18 per cent. For ex-

Shipping Rates Remain

There is no likelihood of shipping rates declining until the general shipping situation is clarified and until the merchant marine of the world reverts to a normal condition. Private ownership of American ships now controlled by the Government will be a quick step toward stabilization of shipping rates.

Best Selling Methods

Direct selling, which means foreign sales through a direct representative, either in the form of a branch, an agency or a jobber, who should be an American citizen, is the best method for promoting foreign trade. No two countries should be placed under one branch. Under the American executive there should be a staff of native salesmen.

Government Interference Dangerous to Industry

"Combinations of Government with industry are as dangerous as Church with State," said Edward N. Hurley, striking one of the major topics of the convention. There was widespread approval of every demand for the return of the railroads to their owners and the sale of the American merchant ships to American individuals. Denunciation of the present practice of the American business man to seek too much Government aid was made frequently.

Parcel Post Trade

Great Britain has parcel post service to 195 countries and U. S. A. to 94. To become a truly great exporting nation we require the steadying and unending aid of an adequate parcel post system. Special attention must be given to small trial orders. Express charge on a 3-lb. package from Chicago to Johannesburg is $15.40, and parcel post from London to Johannesburg for the same weight is 84 cents.

ample a truck now selling for export at $2000 would bring the American maker 500 pounds sterling and the importer would be forced to sell the truck for at least $375 more than the usual retail price, and probably at $500 to $1000 more to make up the extra interest charges, etc.

Consequently the exchange situation is another of the many matters that will affect our exports and is another argument for the establishment of American banks abroad both for simplification of payment, decrease of costs of payment, and for the maintenance of sound exchange rates.

Although many American fabricated products are expected to decline in export with the re-entry of Great Britain in the field, chiefly because British prices are lower, as, for example, with brass goods which Great Britain sells for 20 per cent less, it is not expected that this will be the case with American automotive products; because while they are fabricated commodities they are in an exceptional position due to the fact that American makers are able to supply now and have long been established on a quantity production and low price basis. The automotive industry consequently is one that should be putting its best foot forward, engage in intensive foreign merchandising and make every effort for not only holding but increasing its trade.

Commercial education for foreign trade was given particularly close attention, and emphasis was laid on the need of a good general education as a basis for all members of the export organizations. Considerable discussion ensued with a decided tendency to favor the use of American salesmen abroad and particularly men speaking plain American English, possessed of average American honesty, application and intelligence, who, it was stated, would, when backed with fair prices and the best goods, easily outsell the men who ape foreign manners, customs and peculiarities. Men should be taken from within the home organizations, it was stated, to fill vacancies in the export departments, and should be those who can bring with them thorough knowledge of the production system and home sales plans of the company.

The use of foreign salesmen was decried. Many American concerns lost their export trade organizations with the beginning of the war because they had been employing foreign salesmen.

James W. Hood, president of the Allied Machinery Co., pointed out that England, Italy, France and Germany have never entrusted their export business to foreigners and said American industry must lay a foundation of complete independence from every other nation in all matters involving export trade.

He stressed the importance of developing foreign trade for those of our products which are specialties and believes these will find a ready market the world over. The importance of watching the stocks maintained in the foreign branches and agencies and of turning these at least three times a year, he said, cannot be exaggerated.

Discussion of the use of trade acceptances in export business developed that very little has as yet been worked out so far as foreign business is concerned. The only use of foreign trade acceptances has been made in the Orient, where the concerns draw on the mercantile distributers in the United States. "There was no reason," it was said, "developed to show that foreign trade acceptances cannot become more universally used nor why trade acceptances originating here and drawn on companies abroad should not find their way into the discount market."

Attention of all American industry to the important relation of airships to export business was demanded by Professor Hiram Bingham, lately a colonel with the A. E. F., connected with aviation. He told of the discovery of helium, which a few years ago cost $1,600 a cubic foot to produce as compared with 10 cents a cubic foot now, that to supply the Army prior to the new discovery would have cost $36,000,000,000, as compared with $200,000 now. Great Britain, and especially the Vickers Co., Ltd., are preparing to utilize the new discovery and this country should not neglect it, especially as the supply of helium is in the United States.

England is already building huge dirigibles, arranging ports, light houses and routes, and unless American industry awakens it will find the British manufacturer going to Pekin or Calcutta, as the case may be, in 3 or 4 days to close a contract that American makers will lose because it will take them 3 or 4 weeks to make the same journey.

Great Britain beat the United States in the selection of coaling stations for its marine, and forced us to take what was left, and we will find ourselves in the same situation with regard to aviation if we do not promptly recognize the value of the new discovery.

The use of advertising for promoting export trade was declared entirely feasible and highly successful by several speakers. The use of American trade export publications, it was stated, is particularly successful, and products ranging from high priced machinery to 25 cent cans of talcum powder are being successfully sold by export papers. The use of foreign local newspapers and weeklies is successful, although Sunday newspapers have not the power they possess in the United States.

Billboards, handbills, export publications, local papers, postal bulletins, street

Latin America

Latin America offers the greatest field for export trade. European makers for many years will not be in a position to meet the demands in South America and Central America. All have made money during the war. We must buy their raw materials in return for our manufactured products. Crating instructions must be followed more closely for Latin America than any other country.

Foreign Advertising Successful

Foreign advertising is not a matter of dollars, but of intelligent survey and analysis. Small or large sums can be successfully used for advertising, either in American trade, export publications or local newspapers or weeklies, provided the advertisements are properly written and illustrated and conform to the customs, peculiarities and systems of the individual country for which they are intended. No two countries can be successfully sold by any one advertising plan—each must be separately surveyed and analyzed.

Foreign Trade Dependent on Credit Elasticity

A flexible system for the handling of foreign finances is essential to the welfare of American export, for our foreign trade cannot expand without an elastic system, allowing for simple and easily extended long term credits. We must have a system that gives individual consideration to the customs of individual countries. The use of trade acceptances in the foreign field will simplify our credit problems. Complete machinery for collection and distribution of foreign credit information and for financing transactions and for handling payments is now available.

car and railroad station advertising has all been found profitable, stated Frank A. Arnold of the Frank Seaman Company. He told also that the advertising agencies have awakened to the fact that they must be able to tell prospective advertisers all details of foreign countries, about their population, customs, and buying power per capita. To analyze foreign advertising, for example in Latin America, it is essential to consider that 50 per cent of the people are illiterate and can be best appealed to by photograph and illustration.

Sense Appeal Successful

The sense appeal has been found particularly successful, and the appeal to sight by means of ads portraying automobiles with georgeous upholstery and brilliant finish has been profitable.

Good advertisements cannot be written in English and translated. All agreed on this. In such instances they lose their vigor and force. They should be written originally in the language of the people for whom they are intended. Native artists can better illustrate the advertisements. Color should be emphasized, and the Latin American artist knows how to do it. Trade marks should be played up, price should be prominent and all text or descriptive matter should be brief.

The use of cut-outs, calendars, postcards, souvenirs and attractive illustrative trade literature to be distributed by the local dealer has been found an excellent plan. The greatest stress, however, was laid on export trade publications, which it was stated the natives regard as a monthly or weekly catalog of the American products of the industry represented, and which they regard highly in the case of reputable papers.

The use of local newspapers in Argentina, Brazil, Peru, Australasia, South Africa and the Far East was found profitable by Howard G. Winne, Johnson Overseas Co., who stated that billboards, posters, and handbills were liked in China, posters in Argentina, railroad station advertisements in Uruguay and Argentina, and street car displays in Brazil. He emphasized the need for manufacturers to spend their own appropriations and not send them to dealers for their use for advertising.

Advertising in Foreign Countries

Numerous questions were asked as to the best means for dividing appropriations through the various countries of the world, and all were agreed that in the case of a virgin field it is essential to first make a theoretical survey and an arbitrary appropriation which can later be regulated by results. The keynote of the discussions appeared chiefly to be that a manufacturer planning to advertise abroad should do as he would in his home market—make a survey, analysis, secure experts, use the authoritative trade publications as a medium and for advice, consult advertising agencies, and keep free from uninformed so-called foreign experts.

FOREIGN TRADE REMARKS BY BIG MEN

We are badly inoculated with self-interest in relation to foreign trade policy and imports.—E. A. BRAND, *Tanners' Council of U. S. A.*

—

Europe's action in imposing restrictions is dictated by a policy of self-defense. She will buy little and export much in order to stabilize her position.—JAMES E. FARRELL, *president United Steel Corp.*

—

With the decline of foreign commerce decay sets in.—EDWARD PRIZER, *president Vacuum Oil Co.*

—

We are eager to sell goods abroad, but this is upon the assumption that we will get something for them. As individuals we want cash, but a nation's sales are never made for cash and cannot be.—FRANK A. VANDERLIP, *National City Bank.*

—

Business should not get into the habit of relying upon the government to solve difficulties which can be overcome by ordinary business skill and honest methods.—EDWARD N. HURLEY.

—

If you want foreign trade you must go after it. You cannot get it by sitting in your office and looking at a map of the world.—JOHN J. ARNOLD, *First National Bank of Chicago.*

—

Trade is reciprocal business in and out. Sales only do not mean trade. It has to work both ways.—E. J. PARKER, *The Parker Co.*

Enlargement of our maritime insurance companies was urged in a discussion of this subject, where it was told that many foreign customers, particularly in Latin America, preferred to insure themselves through British companies or other foreign concerns because they earn a commission that they do not secure when the American exporter insures through an American company. The placing of insurance with Lloyds of England was decried because it places our ships under their control and forces our shippers and ship owners to comply completely with British inspectors' demands.

Free Ports

The feasibility of establishing free ports similar to that of Copenhagen was discussed, to permit the importation of materials that could be manufactured into finished products at factories located within the free zone and then exported without incurring duty or tariff. A sort of manufacturing zone, in other words, located within a district similar to the Customs districts where goods are held in bond, was advocated. The history of New York's development and its difficulties to secure legislation for completion of a tunnel under the Hudson and East Rivers, were related.

The discussion emphasized that there would be danger of foreigners importing raw material to their own factories established in such zones and re-exporting the finished product in competition with American manufacturers. It was agreed that the scheme mentioned needed much investigation before any decision could be made.

The difficulties of granting foreign credits, the possibility of exporters combining to obtain data for establishing bureaus to furnish foreign credit and the assistance that should come from our government were among the problems discussed under the head of foreign credits and credit information. "We must look," said E. E. Pratt of the Overseas Products Co., "to the government for a consistent foreign policy with reference to the establishment of stable government and the preservation of the existing economic system throughout the world."

Packing for the A. E. F.

The methods used by the A. E. F. to overcome packing problems were related by Captain H. R. Moody of the U. S. Army, who gave several concrete examples, among which was the army system of handling the Packard truck. "It was found that the original 5-ton Packard truck completely set up occupied 1,000 cu. ft., and after experiments we found that the truck could be dismantled without seriously interfering with reassembly overseas. It was packed in a crate to occupy 268 cu. ft., thus allowing four trucks to go where one had been shipped before.

The convention closed following a decision to hold the next annual meeting in San Francisco, and with a vote of thanks to the various officials.

Willys Profit-Sharing Plan on 50-50 Basis

Establishes Community of Interest Between Workers and Employers—First $400,000 Has Been Distributed

By J. Edward Schipper

THE plan of the Willys-Overland Company to divide the profits of the company over and above the amount reserved for interest upon capital on a 50-50 basis would have been considered sufficiently revolutionary to be ridiculous 4 or 5 years ago. It has been adopted in the past 2 years by a number of concerns and is not even radical enough to be questioned as a general plan. The main interest of the plan arises from the fact that this is perhaps the largest organization by which it has been adopted and is an organization directly in the automotive field. For the same reason the details of the plan should be considered very carefully and the advantage or otherwise of each provision should be noted, for the benefit of the other industrial establishments in this field. While this is no longer radical but ouly good practice, the best of practice being always far ahead of the general method, it is a clear and important mark of progress in the new relations which are being established between employer and employee.—*Harry Tipper.*

ONE of the most important developments in the newer relationship between capital and labor is the profit-sharing plan now in operation at the plant of the Willys-Overland Co. in Toledo. John N. Willys announced last January that he would introduce for the years of 1919 and 1920 a fifty-fifty profit-sharing plan. Summed up in a few words, this plan is outlined in the following statement: "That after permanent capital and permanent labor have each been justly compensated, having due regard to the cost of each (the cost of capital and the cost of living), the additional profits accruing from the joint employment of permanent capital and permanent labor shall be divided equally between them—fifty-fifty."

The thought underlying the John N. Willys plan, which is published in detail herewith, is to create among the men the feeling that they are working with the company instead of for it. The Willys-Overland Co. is taking its employees into partnership and splitting its profits on a fifty-fifty basis.

How this will work out remains to be seen. The first $400,000, representing one-half the profits of the first quarter, has just been distributed. Ten thousand Overland workers have received checks for their share in these profits. The indications are that the plan is going to work well, but with many thousand workmen, large numbers of whom are foreigners, it is not possible to reach them all through the printed word. It is therefore necessary to bring the message home to them by spoken word, often in their own language, and the Willys-Overland Co. is holding meetings five times a day, taking 500 men at a time and instructing them in the details of the fifty-fifty plan.

Some amazing results have been found. When the committee of five, appointed from the ranks of the employees, first started to tell the laborers of the plan, they found that outside agitators, taking advantage of the inability of some of the workmen to understand English, had given distorted ideas as to what the plan meant; and a marked change of attitude and a rapidly growing enthusiasm for the plan developed among these men as soon as it was made clear to them.

An interesting instance may be cited. One of the machine workers—a boy seventeen years of age—approached one of the committeemen and said: "Is it true that we are going to share one-half of what the company makes?" When the committeeman informed him that it was true, the seventeen-year-old workman replied: "Then why don't you turn out your lights during the noon hour?"

Needless to say, his suggestion was quickly acted upon, which resulted in a great saving in current, due to the turning off of thousands of lights throughout the great Overland plant. This is only one instance in many. Hundreds of suggestions and interesting questions are pouring in daily to the office of L. M. Ellis, the chairman of the fifty-fifty committee.

Picking a committee from the ranks of the workmen, so as to be sure that men of high intelligence and knowledge of sociological conditions would be found, presented an interesting problem, and it was solved in an equally interesting manner. The company announced that the committee of workmen to serve on this committee would be selected from those who sent in the best suggestions regarding the working out of the fifty-fifty plan. Sixty-three writers were picked as logical candidates for the committee, and one by one they were called into the office for an interview. An idea of the quality of the men who were called in may be gained from the first five who entered.

The first was a graduate in sociology from an eastern

The Willys-Overland Profit-Sharing Plan

PROFIT DISTRIBUTION PERIODS

Five distributions of profit to employees shall be made each year. The first four of these shall be based on a conservative book inventory and the fifth on the regular annual inventory:

No. 1. Distribution in April, for January, February and March.

No. 2. Distribution in July, for April, May and June.

No. 3. Distribution in October, for July, August and September.

No. 4. Distribution on Dec. 24, for October and November.

No. 5. Distribution in March of the following year to include December, the difference between book and annual inventories, and other adjustments.

Distributions 1, 2, 3 and 5 shall be made as early in April, July, October and March as the necessary records can be completed.

Separate profit-sharing checks shall be distributed.

PERMANENT LABOR

1. Every employee, after 6 mos. of continuous service, shall become a profit-sharer and be classed as "Permanent Labor." In the first distribution thereafter he shall receive a share of the profits which have accumulated from the date of his employment to the close of the period which is being distributed.

2. However, for the purpose of establishing the distributions of April and July, 1919, on a fair basis, profits earned by the company between January 1, 1919, and March 31, 1919, shall be distributed in April to employees who were on the company's employment records for the pay period ending Dec. 18, 1918, and who gave continuous service in January, February and March, credit being given these employees for 3 months' previous service.

Profits earned between April 1, 1919, and June 30, 1919, shall be distributed in July to employees who were on the company's employment record Feb. 1, 1919, and who gave continuous service in February, March, April, May and June, 1919, credit being given these employees for 1 month's previous service.

CONTINUOUS SERVICE

3. Employee's record of continuous service shall not be affected by absence on account of sickness or injury, or if it is by the consent of employer. Absence from work for two consecutive days or three times in 30 days without report and acceptable excuse shall automatically remove an employee's name from the continuous service record.

4. Record of employees absent in military service shall be considered as continuous, provided they make prompt application for re-employment after their discharge from military service. If the date of their application for re-employment is more than 10 days after date of discharge from military service, their eligibility for the continuous service record shall be determined by the Fifty-Fifty Division.

5. If any employee leaves the service of the company after being qualified for profit-sharing for 6 months' continuous service, his record shall be held open until the next distribution, when a final profit-sharing check shall be mailed to his address.

6. If an employee is discharged, the Fifty-Fifty Division shall determine distribution of profits upon the merits of the case.

Note.—The provisions of paragraph three shall take effect April 1, 1919, and shall not operate against an employee's continuous service record before that date.

BASIS OF DISTRIBUTION

In distributing profits, no salary or wage shall be considered as in excess of $5,000 per annum.

As stated in paragraph one of Permanent Labor, employees shall receive payment of profits in the first distribution after the completion of their first 6 months of service with the company. During the 6 months, a share of profits shall be credited to each employee's record, beginning with the date of his employment.

Distribution of profits to permanent labor shall be on the following basis:

FIRST FOUR DISTRIBUTIONS

If profits to be distributed in periods Nos. 1, 2, 3 and 4 amount to 6 per cent or more, but less than 8 per cent, on the total of wages paid in the period to employees whose names are on the last payroll of the period, 6 per cent of the wages paid shall be credited to each employee's record, except that no employee's share shall be less than 4 per cent per hour for each hour worked in the period. If the amount is in excess of 6 per cent, this excess shall be transferred to Distribution No. 5.

If profits to be distributed are 8 per cent or more, but less than 10 per cent, 8 per cent shall be credited, as indicated in preceding paragraph, no employee's share to be less than 4½ cents per hour for each hour worked in the period. The excess, if any, above 8 per cent, shall be transferred to Distribution No. 5.

If profits to be distributed are 10 per cent or more on total wages paid in the period, 10 per cent shall be credited, as indicated in previous paragraph, no employee's share to be less than 5 cents per hour for each hour worked in the period. The excess, if any, above 10 per cent shall be transferred to Distribution No. 5.

If profits in any one period do not equal 6 per cent on the total of wages paid in the period, no payment shall be made for this period (except under Paragraph five of permanent labor), but this amount of profit shall be transferred and added to the profit of the following period.

DISTRIBUTION NO. 5

This shall be based upon profits to be distributed for December, adjustment of book and annual inventories and accumulation of excesses from previous periods. It shall be credited on the basis of the percentage of its total amount to the total amount of wages paid in the year to employees who work in December.

Length of service with the company shall be rewarded by giving an employee an addition of 1 per cent per month to his share of No. 5 distribution for each month of continuous service in excess of 12 months after Jan. 1, 1919, until a maximum shall thereafter be added to such employee's share of each No. 5 Distribution.

PERMANENT CAPITAL

Permanent Capital is the net book value of the assets of the company, not including Good Will, Patents, Trade Marks, etc.

Statement of Dec. 31, 1918, shows the Permanent Capital of The Willys-Overland Co. to be the sum of $79,668,232.92.

COMPENSATION

In arriving at the "Just Compensation" to Permanent Capital, as related to our 50-50 profit-sharing distribution, there must be established—

1. An average rate for depreciation, based on general standard accounting practice, subject to approval of certified public accountants;

2. A reserve for contingencies or "Rainy-Day Fund," at an estimated rate;

3. A just return to invested capital, or cost of securing the necessary capital for investment in the industry.

university and had been a professor of sociology in the University of Illinois, but is now working in the Overland shop. The second is a graduate chemist. The third is a man holding a civil engineer's degree. The fourth was formerly an Irish editor on a German paper, a man whose keen wit and knowledge of human nature made him at once an acceptable candidate for the committee. The fifth has been president of the Toledo Socialist Club and is a keen student of sociological conditions.

With men of this mental caliber coming from the ranks of the workmen, it is evident that the fifty-fifty plan was submitted to the keenest type of minds before it was presented to the workmen. These men having both wide experience and at the same time being fully aware of shop conditions and the psychology of the shop employee, are the best possible judges that could be found, and their endorsement of the plan is a strong prophecy for its success.

John Willys in this plan has taken a long step away from what has been all too common in the past—the treatment of labor as a commodity and not as a group of human beings. This is the basic principle upon which this scheme has been laid out. It is common knowledge that the smaller the shop the less frequent are labor troubles, and the reason is not far to seek. Here capital is in such contact with labor that the capitalist or his representative, the president of the company or other officers, know the men in the shop by their first names. There is a point of human contact which is impossible in the vast industrial institutions which have grown up in the automobile business. Just as soon as this personal contact is established and labor becomes human to the employer, labor troubles become less if the employer is a man of proper disposition and character.

Establishing Point of Contact

Such close intimacy is impossible in a great organization such as the Willys-Overland. In its place there must be some other point of contact. This Mr. Willys is attempting to establish through a community of interest. He is making it as much of interest to the laborer in his plant to have the Willys-Overland Co. show a large profit as it is to the capital element in the concern. When workmen begin to feel that when they waste material or tools they are not only cutting down the profits of the concern but they are taking money out of their own and fellow employees' pockets, they become more careful. This has already been illustrated by the example of the seventeen-year-old worker and the lights. It was shown again in the Overland forge shop, where, when the workmen were informed that for every Overland car $7 is represented in the scrap pile, they were astounded and are already hunting means of reducing this scrap percentage.

Analyzing the plan which is printed herewith in detail, it will be seen that there are five distributions of profit, distribution No. 1 taking in the first quarter, No. 2 the second quarter, No. 3 the third quarter and No. 4 the months of October and November. The distribution for the month of December is made in the following March, and at the same time adjustment is made between the estimated and the actual inventories, and other adjustments. This adjustment No. 5 is popularly termed among the workmen "The Jack Pot." This "Jack Pot" is exciting a great amount of interest and discussion among the employees.

During the first three periods of the year and the last two months of the fourth period, the distribution is made on a straight percentage or time basis, as will be seen under the head "First Four Divisions." All excesses of profits over the percentage distribution go into distribution No. 5. Besides this, 1 per cent is added for each month of continuous service in excess of 12 months after Jan. 1, 1919, until a maximum of 50 per cent is reached. This gives a growing and attractive offer under the No. 5 distribution and not only does it reward the steady employee up to 50 per cent of his pay, but it offers an interesting chance of making a considerable bonus, should the profits of the company be exceptionally heavy.

Some typical questions which are being asked by the workmen, and which are published in *The Willys News*, a paper circulated among employees, are given below. These bring out clearly the thoughts which are in the minds of the men in discussing the fifty-fifty plan. The questions and answers follow:

Question No. 1.—*"Is the six months' continuous service feature fair to the employee who works four or five months during the busy season, and is then laid off when the dull season comes on?"*

Answer.—"The committee has asked Clarence A. Earl, first vice-president, to state what effect the future policy of the company will have on this condition. Mr. Earl makes the following statement:

" 'Our production will soon be limited to two models of a character which will be in demand practically the entire year. We also anticipate so great demand for these that our present capacity and the number of employees must be largely increased. We recognize the great advantage, both to our employees and the company, of continuous production the year around and that was one of our principal reasons for reducing our line to these two models of popular character.

" 'Therefore, there should be no reason why every employee should not have a continuous record of more than 6 months. If there is temporary slackness in a department the foreman can keep the employee on the continuous record until there is work again. Even if an employee should leave a department, for good reason, he will be given first consideration on openings in other departments and his continuous record will not be broken because he changes his clock number.

" 'Granting that conditions which have existed heretofore may have justified this employee's question, it is certainly the policy of the company to do everything possible to change these conditions.' "

Question No. 2—*"I do not understand the last paragraph of the section on 'Basis of Distribution.' Can you give an example of its application?"*

Answer.—"That section reads: 'Length of service with the company shall be rewarded by giving the employee an addition of 1 per cent per month to his share of No. 5 distribution for each month of continuous service in excess of 12 months after Jan. 1, 1919, until a maximum of 50 per cent is reached. This maximum shall thereafter be added to such employee's share of each No. 5 distribution.'

"We believe the following example will show what is meant: If an employee has a continuous service record of 24 months on Dec. 31, 1920, his total wages of say $1,200 for 1920, will be multiplied by 112 per cent and this increased amount, $1,344, would be used as the basis for computing his share of No. 5 distribution, payable in March, 1921. The 150 per cent maximum, on the above basis, would be reached in 1924."

Question No. 3.—*"I do not understand the* 8 *per cent (four and a half cent minimum) distribution. I have worked* 500 *hrs. in January, February and March, and my total wages for those months is* $300. *What will be the amount of my fifty-fifty check?"*

Answer.—"Eight per cent on the amount of your wages is $24; four and one-half cents per hour on your total hours worked is $22.50. You will therefore receive the larger amount, $24."

Question No. 4.—*"Will the profit-sharing checks be considered as a part of the employee's wages?"*

Answer.—"Absolutely no. Mr. Willys, in his announcement, plainly stated, 'These plans will have no influence on periodical adjustment of wages.' "

Organization Plans Should Appear in Time of Industrial Peace

Their Justification Is Increased Production Per Man—Variability of Human Element Is Important Consideration

By Harry Tipper

THE problems which have come up before the manufacturer, in connection with the task of keeping his labor harnessed and producing under conditions that have come to be normal, have caused us to act upon these problems because of the necessity of arriving at some solution in each individual case. It has not been possible to study the situation with sufficient care in many cases to permit of arriving at a solution which would form a basis for future harmony.

When a strike is declared by the men in the shop, or when a grievance has been submitted by the union, either locally or nationally, that particular strike must be settled or that particular grievance must be solved, even though the solution of the grievance, or the settlement of the strike, do not offer any hope of removing the cause of the discontent or laying the basis for adjustment of future disputes before they reach the point of final action. The length to which this necessity of meeting the immediate problem may carry the manufacturer is illustrated by the story of conditions in Great Britain during a portion of the war when the factories were under the control of the Ministry of Munitions.

Compromises Handicap General Solution

It was decided to give piece workers a bonus to cover the increased cost of living. This was done after a series of conferences with the labor organizations and the manufacturers. At the same time it was decided to give a flat percentage increase to the day workers in the shops, so that they would have the benefit of the increased pay in the same way as the piece workers. About every so often a new body of workers brought to the attention of the Government the fact that they had not been included in this increase, until the sweepers and the night watchmen had brought their case to the Government with sufficient force to require their inclusion.

Not long after the skilled workers came back with this original proposition as a demand for further increase. They said: "A year ago we were making 30 per cent more than the helpers, and now we are only making 18 per cent. We need a further increase in the bonus to re-establish former relations," and the whole question of wage increase was reopened, of course. This necessity for meeting the individual and the general problem at all times has forced compromises which have worked against the study and attention which must be given in order to secure a logical basis for the general solution.

It has been stated in these articles, in the earlier part of their development, that no organization changes which attempt to provide machinery for the discussion and agreement upon these points can be made at a time when an immediate necessity has arisen and be of any service in warding off that necessity. If workers are about to present their grievance in respect to wages, or hours, or anything of that kind, and the manufacturer brings out a plan for profit sharing, for joint committees and conferences, etc., at that particular time, the plan which he is bringing out will suffer because of the problem which lies immediately ahead and the attitude of the worker's mind at that moment.

No Suspicion of Motive Wanted

Organization plans which are built up in the hope that they will establish a permanent machinery for the purpose of discussion and examination of these matters must be promulgated at a time when there is no immediate fight on hand and when there can be no additional suspicion of the manufacturer's motive.

In the severity of the warfare which has characterized the industrial development of the last three or four years and the hasty decisions upon problems which have been made we have lost sight of the fact that, no matter what form the organization may take, it must, in the end, justify itself by securing a better production per unit per man, and that it should be based, therefore, upon a study of the factors which govern production and the relative importance of those factors.

The public, as buyers, are interested in the effect on costs to them, and have no particular interest in the division of those costs. This has been illustrated amply since the armistice was signed by the general attitude of all manufacturers or producers, each of whom can tell you many reasons why the price of his own product cannot be reduced, and also inform you of the products which he buys at a cost that he considers entirely unjustified by circumstances and explainable only by profiteering.

The farmer knows the cost of producing his

wheat and other crops, and he can inform you in great detail of the necessity for the price which he is securing. He believes, however, that the price of many of the implements which he buys and the equipment which he must use is unjustifiably high and should be reduced.

The director general of railroads is contemplating a freight increase necessitated by the financial statement of the year's operation. It is considered probable that these rate increases will be necessary to meet the costs of running the railroads. At the same time, the director general refuses to accede to a definite price on steel, expecting that it will and should be reduced further in order to become what is termed normal.

Increased Production Justification of Plans

The object of all organization work which attempts to provide a more logical and harmonious grouping in the industrial plant is to eliminate those indefinite but very real costs due to strikes, personal grievances, absences from work, and to eliminate the equally obvious costs which arise from the lack of incentive and, therefore, the lack of any attempt to use the worker's full capacity. When they are fully developed, these organization plans, therefore, must justify themselves by increasing the unit production per man, enabling his wages to be increased without increasing the final costs, and without eliminating the necessary profit on the capital.

It should be recognized in dealing with human conditions that time is an important factor in their development toward harmony and efficiency, and no immediate effect can be expected which will justify the hope with which the organization changes have been established. The more indefinite factors which affect the total production per man have been neglected for so long, not because of their unimportance, but because of their intangibility, that it will require special work to bring out, as the by-product of organization changes, the increased efficiency per man, which is the ultimate necessity of the case.

Production Depends on Individual

The actual production per man varies between different individuals, and on different days with the same individual. It varies between different shops and different departments in the same shop. It varies with the character of the work, with the character of the surroundings and with the immediate conditions in those surroundings. Up to the present, the average which has been produced has been the only basis upon which the future production can be measured, and this basis has been accepted, although it is obviously a very unscientific basis upon which to predicate production efficiency.

The necessity for the careful and conscientious study of the habit of mind, the aspirations, even the subconscious necessities, of the workers, as well as their living conditions, surroundings at work and the necessities of labor conditions rise out of the fact that it is largely by the examination of these intangible factors that production efficiency can be increased in the future.

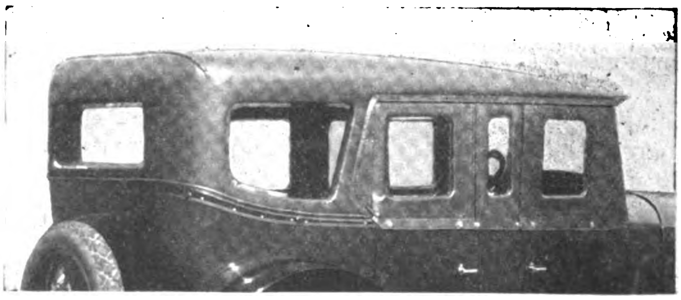
Up to this time the increase of production has come not so much out of the study of the man as it has come out of the development of the machine. When work had to be speeded up and provided at a low cost per unit, new machines have been built which have undertaken the operations in larger quantity in less time and with less handling required. But this development, by the improvement of machines, has arrived at the stage where it is able to affect the production cost only by minute percentages and in connection with minute subdivisions of the total operation. The improvement will constantly grow as human ingenuity is put to the problem of meeting increased cost of production by the development of more rapid and effective machinery.

This development of machinery, however, will not relieve the warfare that exists, the difficulty of maintaining an efficient organization of men, the large turnover among the average workers nor any other of the human problems which lie in front of us. Neither will it take the place of the improvement in production which can be secured by the study of the human element in industry.

During the war it was demonstrated that 50 per cent, 75 per cent and 100 per cent increase in the production from certain machinery could be secured without difficulty when the workers were sufficiently interested in the matter to speed up their own operations, and expend the necessary energy. Such percentages of improvement as this, arising from the satisfaction of just one human desire entering into the work, indicate the field for investigation which lies before the manufacturer and which offers great rewards in production improvement as it is properly investigated and translated into organization operations.

A New Closed Top

At some of the recent Midwestern automobile shows, a new closed top, known as the Class Top, was exhibited by the Consolidated Top Co. of Cleveland, Ohio. At the Detroit show it was shown on a King Foursome car. The half-tone cut herewith shows the appearance of this top. The advantages claimed for it are that it is light and non-rattling, and gives plenty of light for the interior of the car. The windows are all of plate glass. The side curtains are removable, and the valance, that is, the strip against which the doors and curtains abut, can be taken off, leaving the machine of neat appearance when driven without the curtains. Ordinary storm curtains may be used with this top as a protection against rain during the warm season.



Class top shown by Consolidated Top Co.

Michelin steel disk wheels

Disk Wheels for Passenger Cars

Four Years of War Experience Have Shown the Value of Steel Disk Wheels—Michelin and Fiat Leading European Manufacturers—Michelin Wheel to Be Introduced Here

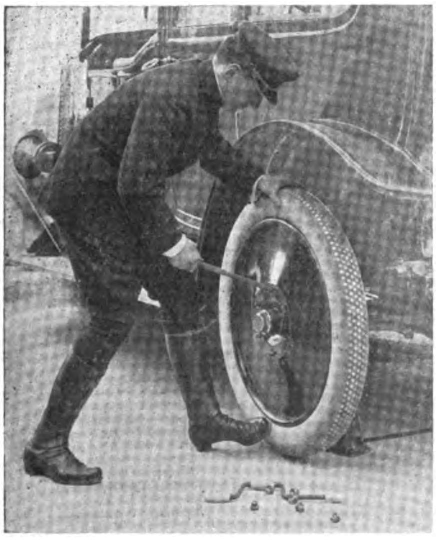
By W. F. Bradley

STEEL disk wheels are a coming feature of French passenger carrying automobiles. Four years' war experience has shown the value of the disk wheel. During the war the two biggest producers of steel disk wheels have been Fiat in Italy and Michelin in France. The former firm equipped all its 1½-ton pneumatic-tired trucks and the great proportion of its touring cars with steel disk wheels. Michelin produced steel disk wheels for a large number of French makes of 1½-ton trucks and for many makes of staff cars. Now that the war is over Michelin is profiting by experience gained and is preparing to produce his disk wheel for touring-car purposes. The programs already laid out indicate that an important number of French manufacturers will adopt the Michelin steel disk wheel as standard equipment.

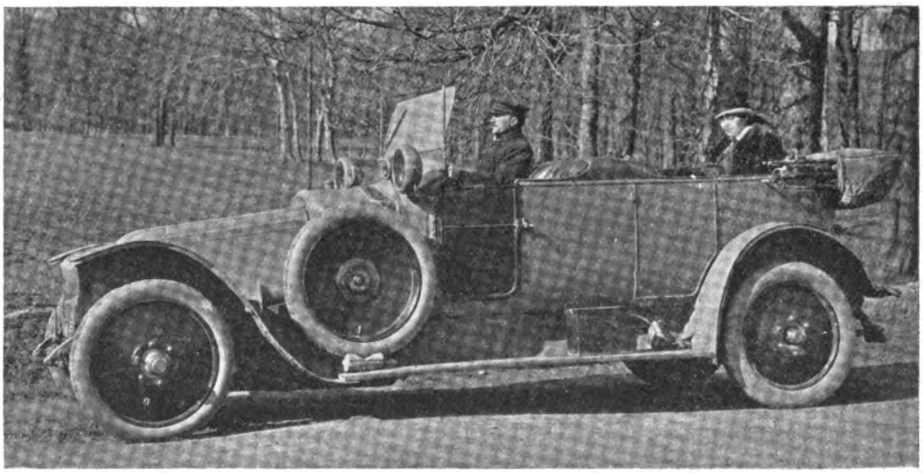
Although similar in general appearance, the Fiat and the Michelin disk wheels are different in construction. Fiat builds up the wheel with three disks, two of them being small and of equal diameter, and riveted to the thin, full diameter disk, which in turn is riveted and spot-welded to the rim.

The Michelin wheel is composed of a single disk, which is stamped out hot under the press and then turned down in the lathe, so that the cross-section becomes thinner as it nears the outer circumference. A wheel which has a thickness of 5 mm. (0.2 in.) at the center tapers to 2½ mm. (0.1 in.) at the outer edge. This outer edge is turned over so as to be at right angles to the main wall of the disk, and is then riveted and welded to the rim. This construction enables the total weight of the wheel to be reduced considerably without any weakness, and has the advantage of removing weight at the most desirable point, namely, near the outer circumference. Attachment is by means of 4, 6 or 8 studs, according to the size of the wheel. These studs, which are fixed in the permanent hub, are of the same diameter throughout their length. The corresponding holes drilled in the wheel, however, have beveled edges, and the nuts by which the wheel is held in position have beveled bases. These two beveled surfaces not only serve to center the wheel in the studs, but have a self-locking effect and make unnecessary the use of spring washers under the nuts. A right-hand thread is used for the right-hand wheels and a left-hand thread for the opposite side.

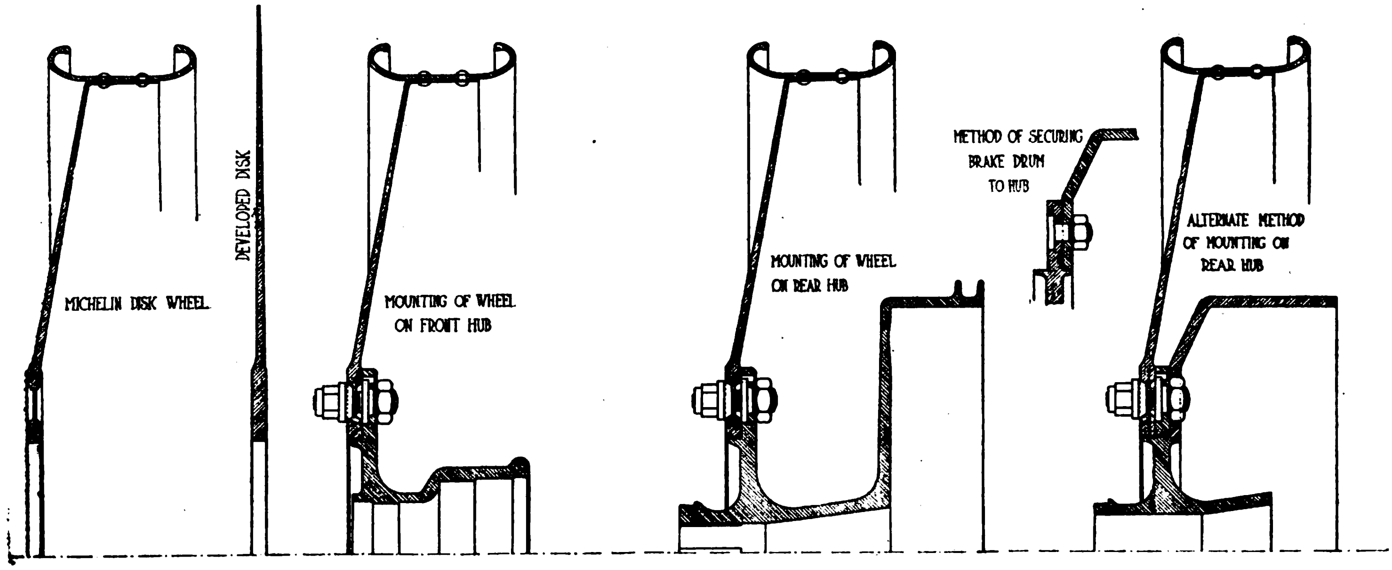
Advantage claimed for this wheel is greater strength than is possible with any wood wheel. The weight is the same as for a wood wheel. There is free radiation of heat through the disk, which tends toward cool running of the tires. Careful experiments have been made in this connection by the Michelin company, which states that the



Fitting Michelin steel disk wheel



Renault car equipped with Michelin steel disk wheels



Sectional views of Michelin steel disk wheel types

tires run perceptibly cooler and that the degrees of heat at various points on the circumference of the disk can be accurately measured. The disks become cooler as the center is reached. The locking arrangement is simple and cannot possibly get out of order.

The usual tool is a brace, but if this is lost any ordinary wrench can be used. The disks are ideal from the standpoint of cleanliness, and add to the streamline appearance of the car.

The European tendency is toward detachable wheels as distinct from detachable rims. Clincher beads are used to the total exclusion of straight-side tires. The argument of European manufacturers is that with the fixed rim and detachable wheel, equipped with clincher tires, a very much lighter wheel is obtained than with the American system of detachable and demountable rims. The European public has never had any experience of straight-side tires, and thus is not in a position to judge of the value of a detachable rim. The argument is also advanced that under the European system of detachable wheels a complete wheel is always available in case of a wheel breakage, whereas under the American system if a wheel breaks the car is held up until another wheel can be procured.

With the Michelin type wheel duals can be fitted very readily and all the wheels are interchangeable. The French are convinced that the dual idea is preferable to big singles. The only precaution is that the two duals shall be fitted as close together as possible. If the clearance is only just sufficient to prevent the walls of the tires chafing, no trouble will be experienced by stones lodging between the two and cutting the walls of the tires. This has been fully borne out by war experience.

The Michelin company will introduce the detachable steel disk wheel to the American market with straight-side beads in place of clinchers. Having proved successful and popular in Europe, and having stood up to all the tests imposed by war conditions, it is believed that this type of wheel will find ready adoption in America. It is a most interesting proposition from a manufacturing standpoint, for while there are many details which must be given careful attention, as has been shown by four years' war experience, the cost of production is low. All Michelin wheels are interchangeable. This simplifies the position of the dealer, who has only to keep in stock wheels of given sizes, without any thought as to the car on which they have to be fitted.

In order to facilitate fitting, Michelin supplies two standardized tools—a brace for tightening the nuts and a tubular lever for lifting the wheel on to the studs. This lever is passed through one of the holes drilled in the hub of the wheel and slipped over one of the studs. In this way the wheel is both guided and levered into position.

Use of War Trucks in Industry and on the Farm

THE contention is made in an article in *Der Motorwagen* of Feb. 20 that many army trucks received such rough treatment that they will be of little use in commercial work. Such abuse causes fatigue of the material employed. This question of fatigue is, of course, taken into account when a vehicle is being designed, but, of course, the stresses ordinarily provided for will, in many cases, have been considerably exceeded owing to the mishandling the vehicles will have gone through.

The overloading, which will generally become apparent by marked, permanent deformations of the various parts of the vehicle, will have as concomitant a depreciation of the properties of the material, especially its strength, by unsuitable treatment in field repairs, *e. g.*, wrong heat treatment and the like, which will leave no external traces behind.

If a "demobilized" truck, then, is to be made even partially reliable as a vehicle for peace purposes, it will not suffice to simply repair it in the ordinary way and re-varnish it, afterward passing it over to the customer. Every firm of repute will certainly see that all the most important components, even those exhibiting no external damage, are tested for strength. This is easier said than done; for a strength test with the Brinell machine can only indicate local strength at the particular place where the test is taken. Again, difficulties arise in heat-treating the parts owing to risk of spoiling machined parts and to shrinkage after heating.

There is, of course, the possibility of making a systematic endurance test of the valuable parts under working conditions on the test ground, but this method, besides being expensive and taking time, gives no reliable data for the value of the part tested.

After all these considerations, the writer comes to the conclusion that in view of the fact that the German reputation for quality has still to be maintained, demobilized trucks, etc., should be hired out by the government to help in the next harvest and get over the shortage of draft animals, and then sent back to the factories that built them, and scrapped.

Thus the heavy vehicle industry would be able to get a certain amount of raw material at a time when materials are extremely short. In this way firms would be able to supply practically new vehicles (or at least very good "rebuilds") to business people in a small way and to farmers.

Sparking Power of Magnetos

Oscillograms Showing Electromotive Force Across Contact Points of Breaker and Current Flowing in Ignition Circuit for Five Different Points of Interruption

By Harry F. Geist, E. E.

IN an article on "Generation and Storage of Energy in Magnetos," published in AUTOMOTIVE INDUSTRIES, Vol. XL, page 411, the writer derived some rules regarding the range of energy storage in magnetos designed for ignition purposes, and illustrated a graphic method (Fig. 7) for determining the stored energy range.

It is the purpose of this article to present an analysis of the energy delivery in the ignition spark by a magneto, for different armature positions over its energy range, showing the amount of the energy delivered, its ignition power, the duration of energy flow and various other characteristics, including coincident losses.

This analysis will be based upon oscillographic records taken directly from the ignition spark, and inasmuch as the same magneto was used as in the above mentioned article, this analysis may be regarded as a continuation of that article.

There is a very marked difference between the amount of energy stored in a magneto (and apparently available for a spark) at any particular armature position and the amount of energy of the spark produced when the circuit is suddenly interrupted while the armature is in that position. This difference is due to the fact that the spark, which represents the energy dissipation during the change from short circuit to open circuit, has a duration of only a few thousandths of a second, and being the result of a very quick magnetic readjustment, the attending iron losses are very heavy.

It will furthermore be shown that for armature positions in the early part of the sparking range, when the machine is generating energy for storage at a high rate, an interruption of the circuit for a spark will not only result in an expenditure of the stored energy, but the spark will also receive energy that is generated directly due to the motion of the armature during the sparking period. This latter point is a very important consideration where springs are used in driving the magneto.

In order to illustrate the study of the ignition spark and to show the true sparking range of the magneto, the oscillograms, Figs. 1, 2, 3, 4 and 5, are presented as records of sparks taken at five different armature positions within the energy range of the magneto. These positions are 10, 40, 70, 100 and 120 deg. respectively beyond the vertical position, at a speed of 600 to 625 r.p.m.

As the duration of the spark is only a few thousandths of a second, in making these oscillographic tests, the photographic drum was revolved at a high speed, so that the phenomena occurring during sparking would be drawn out sufficiently along the time ordinate, and measurements could be made from the record with a fair degree of accuracy. The speed of the drum was from 1000 to 1200 r.p.m. The armature of the magneto was rotating at only about half the speed of the film drum, and in order to insure that the phenomena of sparking would be recorded on the film free from other disturbances, it was necessary to "time" the make and break igniter with the oscillograph just as "timing" would be done on an engine, and it was also necessary to have a switch key in series with the oscillograph shutter circuit for manual control, so that only one spark would be recorded during the operation of the set-up. With this synchronized test arrangement, a simple change in the relation of the armature to the igniter gave the results for the different armature positions desired, for each successive test.

The oscillograph used was a three galvanometer type instrument, so that it was possible to take a record of three electrical forces simultaneously.

In each of the five oscillograms presented, the upper curve shows the voltage across the contact points of the igniter and represents therefore the electromotive-force curve of the spark. During the period of closed contacts, the voltage was, of course, nil, so that the instant when the igniter contacts separate is indicated on the oscillograms by the rise of the voltage curve from the zero line. This point is denoted on the oscillograms by the vertical line marked "Break."

The general nature of the induced voltage curve is the same in all five records. It is shown how the voltage of the spark increases very rapidly toward its maximum as the energy is dissipated in the spark, and then drops off to the open circuit voltage value for the particular position the armature happens to be in, until the con-

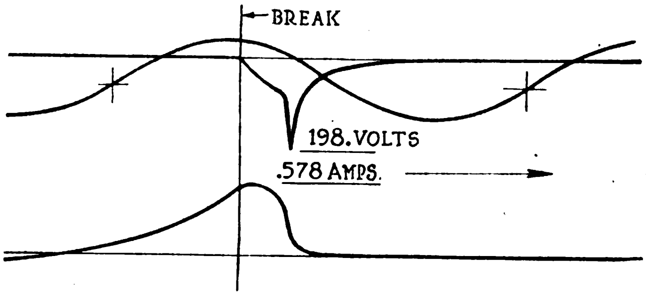


Fig. 1—Armature about 10 deg. beyond the vertical position

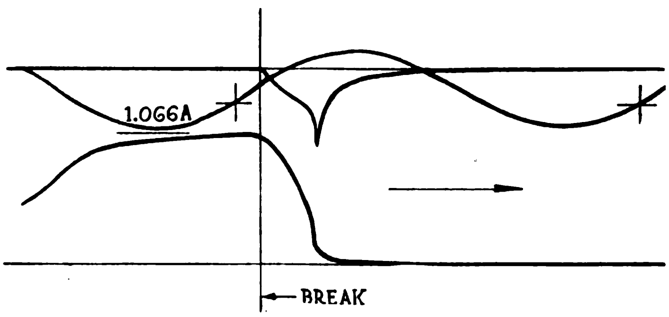

Fig. 2—Armature about 40 deg. beyond the vertical position

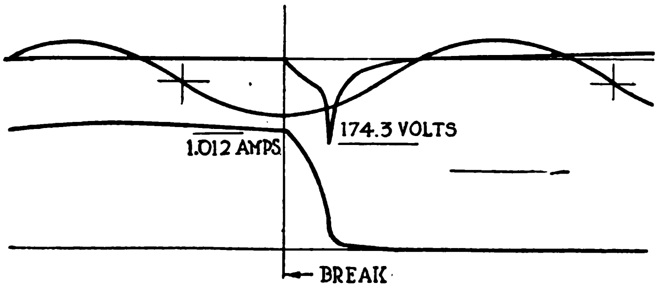

Fig. 3—Armature about 70 deg. beyond the vertical position

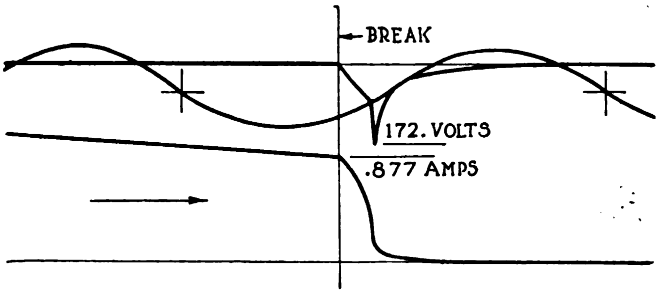

Fig. 4—Armature about 100 deg. beyond the vertical position

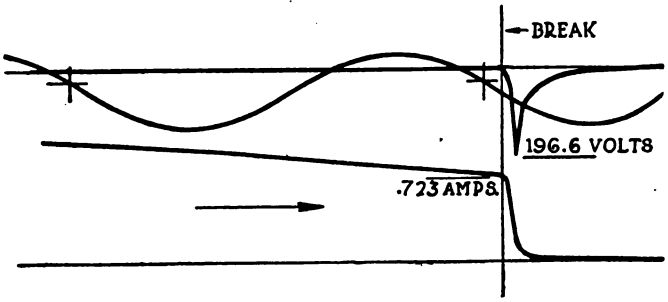

Fig. 5—Armature about 120 deg. beyond the vertical position

tacts close again. It is this induced e.m.f. maximum that tends to break down ignition insulations. Special attention is here called to the fact that this e.m.f. does not attain its peak value until practically all of the energy has been spent in the spark.

The lower curve in each case shows the current generated during the closed circuit periods, up to the instant of contact point separation, as indicated by "Break," and the manner in which the current continues to flow through the circuit formed by the spark, dropping off as the stored energy of the circuit expends itself in the spark. The period required for the current to drop to zero is therefore a direct measure of the duration of the spark.

The third curve, which is practically a sine wave, represents an ordinary 60-cycle lighting circuit wave, and is therefore a direct time calibration of the oscillograms in that the distance between crosses in each case represents 0.01666 second. The arrow shows the sequence of events.

Fig. 1 of the article referred to in the opening paragraph of this article shows an uninterrupted short circuit current wave of this same magneto, for one complete revolution of the armature and at practically the same speed at which these five sparks were taken, so that the generated currents in these five oscillograms represent the same current wave. This fact served as a check on the determination of the armature positions at which the sparks were received.

A study of Fig. 1 of this article shows that, following the interruption of the circuit, the current rises slightly to a maximum value of 0.578 ampere from 0.508 ampere at the instant of break. This current increase during sparking is due to the fact that at the 10 deg. armature position the magneto is generating energy at a very high rate, as is manifest from the rate at which the current increases just before interruption, and the additional circuit resistance at the beginning of the spark is not sufficient to check the current generation immediately. This means that energy is generated and delivered directly to the spark.

The sparks of the oscillograms, Figs. 2, 3, 4 and 5, have the characteristics of low tension sparks and show the current drop following break immediately.

Theory of the Spark

Before entering upon a quantitative analysis of the data presented in these oscillograms, it may be advisable first to develop some of the theory of electrical sparks of this nature into usable laws in the form of mathematical equations to which this data will be applicable.

When the energized circuit is suddenly interrupted to produce a low tension spark, the separation of the contact points drawing out the spark is equivalent to suddenly inserting additional resistance into the circuit. It is evident that this spark resistance r_s is a variable. It is, therefore, evident that during sparking the resistance of the complete circuit will be the sum of the coil resistance R and the spark resistance or $(R + r_s)$.

It is a well-known fact that the rate at which electrical energy is expended in a circuit having resistance is equal at any instant to the product of the instantaneous current flow squared and the simultaneous resistance value. The power or rate of energy expenditure in this case, neglecting iron losses for the present, is

$$p = i^2R + i^2r_s, \qquad (1)$$

where i denotes the current at any instant.

In equation (1), i^2R represents the rate at which energy is lost in the coil at any instant, while i^2r_s represents the power of the spark for the same instant. If the current is expressed in amperes and the resistance is expressed in ohms, then the rate of loss and the power will be in watts.

Inasmuch as we are interested at this time more particularly in the power of the spark, it will be better to separate it from equation (1) by the following equation

$$p_s = i^2r_s \qquad (2)$$

Owing to the fact that r_s cannot be ascertained by direct measurement, this equation for the spark power is not usable in its present form, but we know that the induced voltage across the contact points must be equal to the voltage drop across the contact points at any instant; that is, equal to the product of the current flow and the resistance, or

$$e_s = i\,r_s, \qquad (3)$$

so that equation (2) can be rewritten in the form

$$p_s = e_s\,i \qquad (4)$$

In this equation e_s and i are the varying voltage and current, respectively, for the spark as recorded in the oscillograms, Figs. 1, 2, 3, 4 and 5, so that it is evident that from the data contained in the records it is possible to calculate the power of the spark for any part of its duration.

When it is considered that the total duration of the spark is only a few thousandths of a second, the remarkable nature of these oscillograms must be apparent.

We also know that in an electrical circuit in which energy is expended at a rate P, for a period of time T, the amount of energy expended will be

$$W = PT = EIT. \qquad (5)$$

If P is expressed in watts and T in seconds, W will be expressed in joules.

Under the conditions here considered, the current and the voltage vary, so that the power varies during the life of the spark. The energy equation of the spark is therefore

$$W_s = \int_o^t p_s \, \delta t = \int_o^t e_s \, i \, \delta t \qquad (6)$$

in which the limits o and t express the duration of the spark in seconds of time, o being the instant of "break."

From equation (6) it is seen that, if the manner in which p_s varies with t can be determined for the whole duration of the spark, the total amount of energy represented in the spark is readily obtainable by integration in electrical units which can be converted into heat units by simple multiplication.

By applying the data represented in the five oscillograms to equations (4) and (6), the power and the total amounts of energy of each of the sparks can be determined, as well as other sparking characteristics that will be shown in the calculations.

Quantitative Analysis of Oscillograms

To illustrate the study of the oscillograms, and the use of the equations presented, the spark represented in Fig. 2 may be analyzed as follows:

A series of vertical lines 1/32 to 3/64 in. apart are first drawn from the base line up covering the entire period of sparking; that is, this series of lines covers the period required for the current to drop to zero. The period of sparking is thereby divided into a number of small increments of time δt.

By measuring the time represented by the distance from the line of "Break" to each of the series of lines in succession, and measuring also the current and voltage at each of the instants represented by these parallel lines, then multiplying these simultaneous current and voltage values as per equation (4), and plotting the products obtained against the time after the break, we obtain the power-time relation of the spark directly.

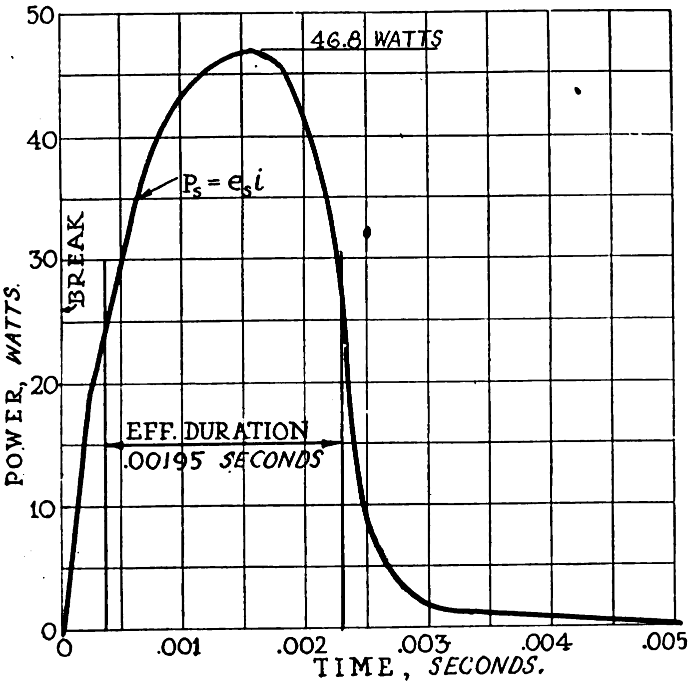

Fig. 6—Spark power curve, showing effective and total duration

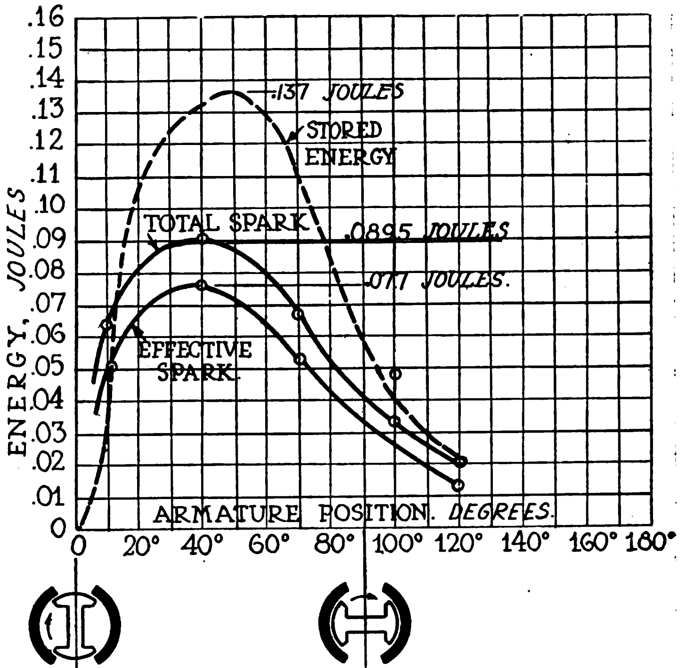

Fig. 7—Showing the true sparking range at constant speed

Such measurements and calculations based on Fig. 2 are given in the following tabulation:

t Seconds	i Amperes	e_s Volts	p_s Watts	r_s Ohms
0.0000	1.066	00.00	00.00	00.00
0.000191	1.047	14.95	15.65	14.28
0.000381	1.018	24.90	25 35	24.42
0.000571	0.970	34.85	33.80	35.90

0.000952	0.864	49.80	43.10	57.70
0.001143	0.806	54.80	44.20	68.10
0.001333	0.739	62.20	46.00	84.20
0.001524	0.672	69.70	46.80	103.50
0.001714	0.604	74.70	45.20	123.50
0.001905	0.509	84.60	43.10	166.00
0.002095	0.423	94.60	40.00	223.00
0.002285	0.192	122.00	23.41	635.00
0.002476	0.096	127.00	12.20	
0.002666	0.058	92.10	5.30	
0.002857	0.038	69.70	2.68	
0.003100	0.029	54.80	1.58	
0.003430	0.024	34.85	0.85	
0.003810	0.019	24.90	0.48	
0.004190	0.014	19.90	0.29	
0.004570	0.010	14.94	0.14	
0.005330	0.000	9.96	0.00	

Besides the calculated spark power, this tabulation shows calculated values of the spark resistance, which are obtained by dividing e_s by i. These present an idea of how the spark resistance increases during the life of the spark.

The relation between p_s and t shown in the above tabulation is plotted to scale in Fig. 6.

A study of this spark power curve reveals the manner in which the spark power increases from zero at the instant of "break" to its maximum value of 46.80 watts and then drops off again to zero as the energy is dissipated.

From this maximum value of 46.80 watts, it is evident that the power of an ignition spark from this magneto is momentarily equal to the power of a good-size incandescent lamp. This power being concentrated in a small arc, the intensity of the heat must be very great.

The total duration of this spark is about 0.00533 second, though it is apparent from Fig. 6 that most of the energy is spent in less than half that time.

It has been the observation of the writer that, to be effective, under the usual conditions of service the power of the spark must exceed 25 watts.

In Fig. 6, the period during which the power of the spark exceeded 25 watts is included between the two parallel lines, and measures about 0.00195 sec.

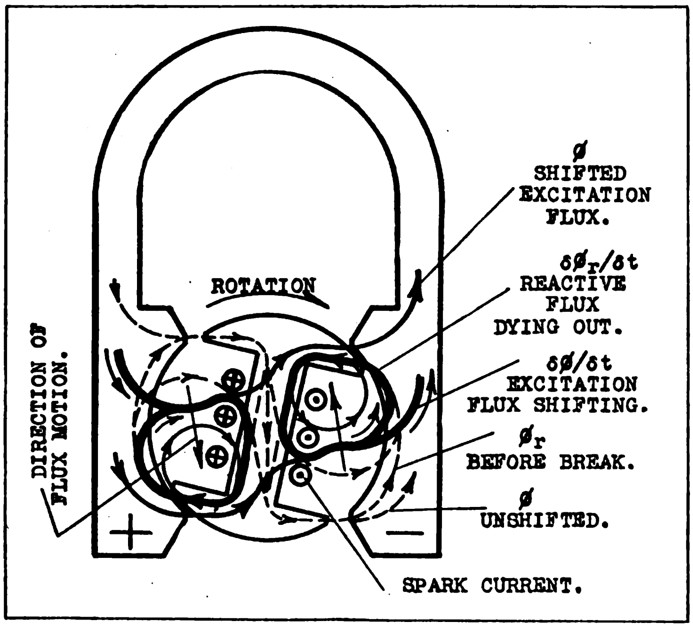

Fig. 8—Induced voltage producing spark current is caused by the flux shifts $\delta\ (\phi + \phi_r)/\delta t$

In order to determine the energy represented in the spark as per equation (6), it is only necessary to ascertain the area enclosed by the power-time curve and the zero power line and to multiply that area by the joules (watt-seconds) per unit of area as determined by the coordinates of the power curve.

Such an integration may be made by adding up a series of products obtained by multiplying the spark power by the increments of time, but the simpler method is to measure the area enclosed by the curve by means of a planimeter and to multiply the area obtained by the energy per unit of area.

Fig. 6 was measured by means of a planimeter, and the total energy of the spark was found to be

$$W_s = 0.0895 \text{ joule.}$$

In like manner, by measuring that portion of the spark between the effective time limits, the effective energy of the spark was found to be

$$W_s \text{ (eff.)} = 0.077 \text{ joule.}$$

From these two values it is seen that 86 per cent of the total spark energy was delivered at a rate exceeding 25 watts.

In a like manner, all the sparks represented in the other oscillograms were analyzed, and showed the following tabulated results as to maximum power, total energy, effective energy, percentage of effective to total energy and effective duration.

Spark at	Max. Power, Watts	Total Energy, Joules	Eff. Energy, Joules	Eff. Total, Per Cent	Effective Duration, Seconds
10°	44.25	0.0659	0.0497	75.4	0.00146
40°	46.80	0.0895	0.0770	86.0	0.00195
70°	46.12	0.0669	0.0557	83.2	0.00148
100°	37.80	0.0472	0.0346	73.3	0.00107
120°	36.90	0.0218	0.0138	63.3	0.00040

A study of the above results shows that all the sparks reached a comparatively high maximum power, but it will be noticed that before and after the 40 deg. position, which seems to be about the position for maximum spark in this magneto, the amount of energy involved in the spark drops off quite rapidly with an accompanying shortening of the effective duration. The last two sparks were low in energy and of short duration and would be very poor for ignition service.

In the total and effective spark energy values for the five different sparks at known armature positions, we have data with which to plot the true sparking range of the magneto for the speed at which it was tested.

The above energy data are plotted against armature position in the curves shown in Fig. 7. Included in this figure in dotted line is also the stored energy curve shown in Fig. 7 of the article referred to in the opening paragraph of this article.

In general, the difference between the amount of stored energy for any armature position and the amount delivered to the spark for the same armature position gives directly the amount of energy spent in iron and copper losses during sparking.

For the early armature positions, *i.e.*, in the neighborhood of 10 deg., this does not hold true, because, as previously pointed out, energy is generated and delivered directly into the spark. However, for the 40 deg. position, a very good idea of the amount of the losses accompanying sparking can be obtained.

Losses Coincident to Sparking

The total loss for the 40 deg. position is seen to be the difference between 0.137 joule stored and 0.0895 joule delivered and equals 0.0475 joule, or 34.7 per cent of the energy available and 53.1 per cent of the total energy actually delivered.

Of this amount, the copper loss was found by the use of the equation

$$W_c = \int_0^t i^2 R\, \delta t, \qquad (7)$$

which for the 40 deg. position gives an energy loss of 0.0058 joule. Copper loss during sparking is therefore seen to be very small.

The iron loss by difference is therefore

$$W_f = 0.0417 \text{ joule}$$

or 30.4 per cent of the energy stored and 46.5 per cent of the total energy delivered to the spark.

This high iron loss can be attributed to the very quick shift of magnetic flux in the magnetic circuits of the machine during the very brief period in which the phenomena of sparking occur, and it would seem that there ought to be room for considerable improvement in magnetic circuit design in this type of magneto, inasmuch as the machine analyzed is representative of the type.

Magnetic Motion During Sparking

Fig. 8 is shown to give an idea of the magnetic shift that takes place during sparking. This diagram shows the loops of reactive flux dying out across the turns of the coil on both sides of the machine, in the direction of the arrows indicating flux motion. As the reactive flux dies out toward the magnetic center on each side of the coil, the excitation flux will also sweep across the coil turns to take its natural path from the lower tip of the positive pole up through the armature core to the upper tip of the negative pole. In making this sweep it follows the reactive flux in motion, so that the induced voltage producing the spark current is caused by the combined flux shifts represented by the expression $\delta(\theta + \theta_r)/\delta t$ as shown. The magnetic lines shown in dotted lines illustrate the magnetic flux distribution just before the "break" took place.

The fact that practically all the flux reverses its path completely in the armature core and sweeps across the total embrace of the pole pieces in the very short interval of about 0.002 second ought to explain why the iron loss during sparking is relatively very high.

It may be of interest to know what factors determine the duration of a spark resulting from the interruption of an energized circuit.

Every electrical circuit has what is known as a time-constant that expresses the time required for the energy to increase or decrease in response to changed conditions.

This time-constant is roughly defined as being proportional to the inductance of the circuit divided by the circuit resistance, and the relation is such that if the inductance is expressed in henrys and the resistance in ohms, T will be the time in seconds for the energy to go through a certain percentage of the total change due to a change in circuit conditions. In its general form it is expressed as follows:

$$T\text{, seconds} = \frac{L\text{, henrys}}{R\text{, ohms}} \qquad (8)$$

It will, however, be found that T is a fair criterion of the sluggishness or the alertness of an electrical circuit.

The instantaneous resistance of the circuit during the sparking phenomena was shown to be $(R + r_s)$, so that the time constant of the circuit for any instant during sparking becomes

$$T = \frac{L}{R + r_s} \qquad (9)$$

From this equation it is evident that the circuit "quickens" as r_s increases during the life of the spark, as shown by the values of r_s given in the table calculated from Fig. 2.

As an example of the use of equation (9), the following substitutions are made in that equation.

The inductance L of the circuit for the 40 deg. armature position of the magneto tested was shown in Fig. 6 of the article previously referred to, to be about 0.138 henry. The resistance of the winding was 4.02 ohms. Taking the value of the spark resistance at the instant one-half the effective energy was spent as an average value, the resulting value of T as the time-constant for that instant ought to be about equal to the effective duration of the spark. The value of r_s equal to 84.2 ohms at an instant 0.001333 second after break is taken as about an average value. These values substituted in (9) give the following results:

$$T = \frac{0.138}{4.02 + 84.2} = 0.001565 \text{ second.}$$

Comparing this value with the 0.00195 second actually required for most of the energy to spend itself in the spark, and allowing for the limitations in the use of T for specific calculations, it is very evident that the prominent factors in equation (9) do control the duration of the spark.

These two prominent factors are the inductance of the circuit and the spark resistance. Of these two factors, the inductance depends upon the design of the circuits of the machine, while the spark resistance depends for its value at any instant upon the amount of contact point separation and the energy involved.

Since the energy available is independent of the rate of spark point separation, it is evident that the quicker the contact points separate the quicker the energy will be spent in the spark and the higher its power will tend to be. The spark will also increase in volume for higher rates of contact point separation. Thus it is seen that a magneto of this type depends in a measure upon the igniter for the character of its behavior, as well as upon its own characteristics.

In the case of a high-tension magneto, an analysis of the sparking ability can be made in the same general way as that herein shown for the low-tension magneto, by making similar tests upon the interrupted primary circuit with the condenser disconnected. It would also be preferable to make the tests with the secondary removed if possible. The results thus obtained, supplemented with tests made with the secondary in place and the condenser connected and including records of the high-tension spark current, would give a very complete analysis of the high-tension type machine.

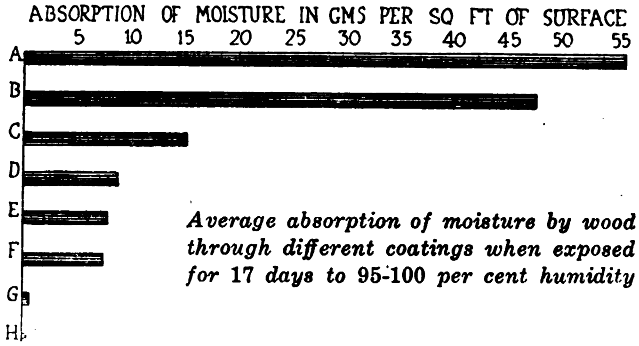
Aluminum Leaf to Moisture-Proof Wood

A VERY effective agent for moisture-proofing wood has been found in an aluminum leaf coating. This coating practically insulates the wood against any change in atmospheric conditions, and is therefore particularly valuable for use where exceedingly accurate form and balance must be maintained, as in an airplane propeller.

The comparative effectiveness of aluminum leaf, spar varnishes, enamels and other water resistant finishes tried out by the Forest Products Laboratory is shown in the accompanying graph. Aluminum leaf coating, it will be seen, is about 25 times as moisture resistant as the average spar varnish.

Two types of aluminum leaf finishes have been used, which are about equally impervious to moisture. One makes use of spirit varnish and the other of oil varnish, the successive coats being as follows:

Spirit Varnish Type—Filler plus 1 or 2 coats of orange shellac plus 1 coat spar varnish used as a size plus 1 coat



Average absorption of moisture by wood through different coatings when exposed for 17 days to 95-100 per cent humidity

aluminum leaf plus 2 coats of orange shellac with desired color plus 1 coat spar varnish.

Oil Varnish Type—Filler plus 1 or 2 coats spar or rubbing varnish plus 1 coat spar varnish used as a size plus 1 coat aluminum leaf plus 2 coats spar varnish or enamel.

Coating wood with metal leaf is not nearly so slow a process as laying leaf in sign-making. As soon as the size reaches the right condition, the leaf can be applied directly from the book without the aid of gilders' tips or necessity of skilled workmanship. The time required to apply leaf to a propeller should not be more than 40 or 50 minutes, and this could be reduced as the finisher becomes more experienced.

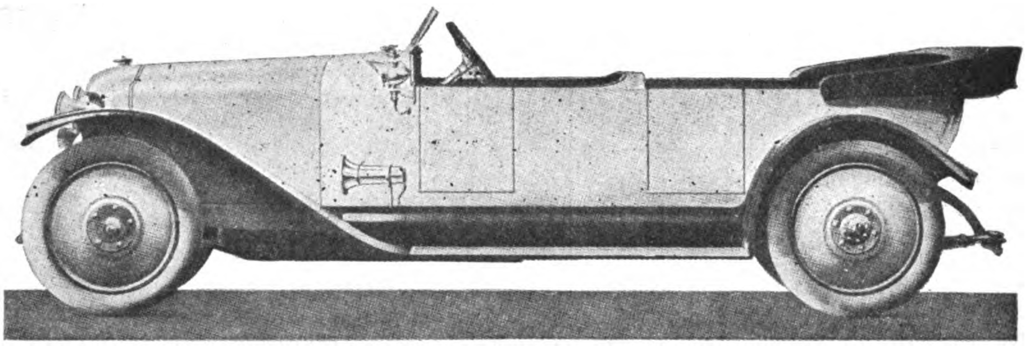
It is important to allow the size to reach the proper condition before attempting to lay the leaf; the right point is just before the varnish sets dust free. The time required to reach this condition varies with the type of varnish used, but for spar varnishes it is usually from 1½ to 2 hours after application. The workman will soon learn how to judge the condition of the size by touching it lightly with his fingers. The size will dry much quicker if it is thinned about one-fourth with turpentine. It should be applied as sparingly as possible.

To apply the complete finish of the spirit varnish type requires in the neighborhood of 10 hours and to dry the various coats about 90 hours, making the total time about 100 hours. The oil varnish finish takes longer to dry and would probably total 240 hours. The latter finish is possibly the more durable coating.

BALL bearings have been extensively adopted in Germany during the war on account of the scarcity of oil and the small quantity required by this type of bearing, it being found possible to run continually for six months on one charge of oil. Reduced friction and the fact that these bearings could be made entirely of steel, when brass and other suitable metals were difficult to obtain, also contributed to their general adoption.

New DeDion Eight-Cylinder Model

Many Former DeDion Features Discarded—Gearbox Unit with Engine and Rear Axle of Conventional Design—Gear Drive for Camshaft



THE type H G DeDion-Bouton, which is one of the new post-war models, is an eight-cylinder design, with 70 x 120 mm. cylinders, and is made with 134⅜-inch wheelbase. It incorporates many innovations in DeDion-Bouton construction, among which might be mentioned hinging the gearbox as a unit with the engine and the use of a conventional type of rear axle in which the drive-shafts are carried in the axle housing instead of the dual type of DeDion formerly used, which incorporated a solid one-piece construction for supporting the load and the differential carried on the frame with cross-shafts driving to the wheels.

In 8 weeks a series of 250 chassis will be under construction in the Paris factory and deliveries will start in America toward the end of May.

The greatest changes made are the elimination of chains in the motor for driving the camshaft and accessories, and the driving of these by gear. The camshaft is made with sixteen cams instead of eight. In other words, there is a separate intake cam for each pair of cylinders. Formerly small levers were interposed between the cams and the valve tappets, but these have been eliminated and now the tappets bear directly on the cams.

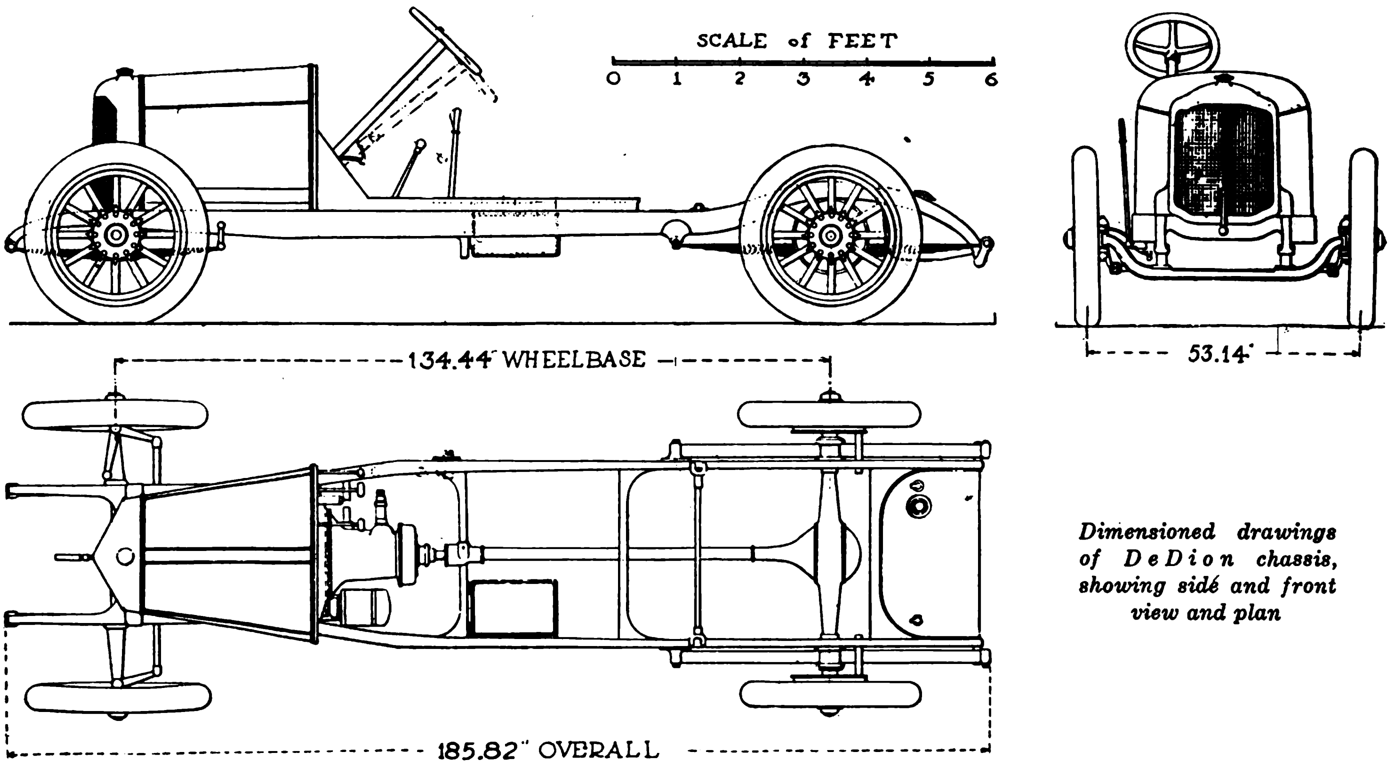
Larger hollow wrist pins are used. Pistons are made of special aluminum alloy, which formerly were of cast iron. Larger diameter valves are used and are placed in side pockets, the same as formerly. The valve stems do not parallel the cylinder bore, but are placed at an agle thereto, so as to reduce the volume of the valve pocket.

The electric lighting and starting system is the DeDion-Bouton, of 12 volts, with dynamo and starter in one unit mounted on the gearbox to the left side and driven by a silent chain.

A new design of clutch is employed, permitting of passing from fourth to low as easily as it was formerly to go from fourth to third at 20 m.p.h. No couplings are used between the engine and the clutch.

Either Michelin disk wheels or special demountable artillery wood wheels are furnished. The tire sizes are 880 x 120 mm., which is approximately 34 x 4½.

A hollow aluminum steering wheel, finished with baked enamel, is used. The worm and sector type of steering gear is used. There are three brakes—expanding serv-



Dimensioned drawings of DeDion chassis, showing side and front view and plan

ice type on rear of the gearset and expanding type on the rear axle, both sets being faced with Raybestos. Adjustable control pedals are used. The accelerator pedal is used for the first time by DeDion.

Special flat semi-elliptical springs are used front and rear, the rears measuring approximately 59 inches in length and the fronts 39 inches. Fan belt drive is used. There is a four-speed gearbox with shaft in a vertical plane. The rear axle is a floating type with stamped housing and helical gears.

The radiator is a V-type with a core housed in a red copper frame. Thermo-syphon cooling is used. The steering gear is on the right side. The hood is made in two parts and separately hinged so that one can be entirely removed without disturbing the other. Pressure or vacuum fuel feed is used. When pressure feed is used there is an auxiliary tank on the dash, of 50 litres, or a little over 13 gal.

The speedometer is driven from the gearset brake-drum. The chassis with 1500 lb. of dead weight in passengers did over 60 m.p.h. The tread is standard of 56 in.

In August the DeDion-Bouton company will have a new eight-cylinder, 12-30 hp. car which will follow the same general design as this model, which is rated at 18-40 hp. In December DeDion-Bouton will market a Grand De Luxe model with sixteen cylinders. The DeDion-Bouton factory has been trebled in capacity since 1914. It has recently purchased the Vinot et DeGniguand plant and also purchased a lumber yard and distillery so that they will have capacity for their large new plant which is contemplated. A new body building plant has been built.

DeDion-Bouton will shortly open up a New York salesroom under the direction of E. Lascaris and J. H. Stelling as sales manager, both of whom have been with the company for many years.

A Striking British Post-War Car

THE car illustrated is a product of the Arrol-Johnston Co. of Dumfries, Scotland. It is remarkable for being well out of the ruck of pre-war European car design and for having much in common with American practice. Mechanically its chief features are overhead valves in a detachable cylinder head, a 2:1 stroke bore ratio, a four speed and reverse gear with central lever control, a spiral bevel gear axle and center fulcrumed cantilever spring suspension in the rear. Another characteristic is the remarkable lightness, the chassis complete with tires and electric starter and generator weighing only 1344 lb., and the complete car well under 2000 lb. A glance at the layout will show traces of American influence, making for cheapening and expedition of quantity production. The car has been well received, where seen, but it will be some time before deliveries can be looked for.

There are four cylinders with overhead valves and a demountable head. The bore and stroke measures 75 mm. by 150 mm. (nom. 3 in. by 6 in.). The equipment includes a separate unit dynamo and electric starter, h.t. magneto ignition, carbureter, forced water and oil circulation, the water pump being enclosed and of special design, and the oil pressure-fed to all bearings.

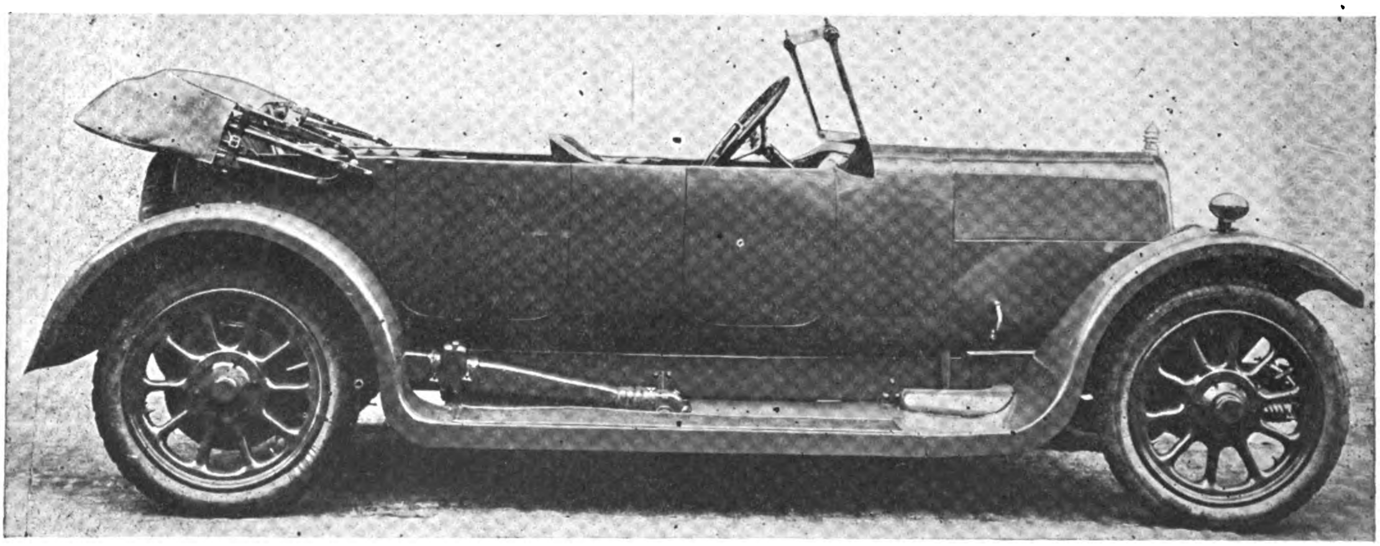
The clutch is an internal cone faced with asbestos fabric. There are four changes of speed and a reverse, with central gate change lever; i. e., the lever is over the gearbox. A special lubrication system is fitted, dispensing with the usual practice of removing the gearbox lid for filling. The rear axle drive is by a spiral-bevel gear, with special provision for self-lubricating, the hubs being furnished with self-adjusting oil retainers and ball bearings.

The steering gear is a worm and sector with special provision for adjustment. The hand wheel is 18 in. in diameter, and the steering post contains in a special casing the control levers and speedmeter and oil gages. The steering rods have a novel form of oil-retaining joint which dispenses with the hitherto-used dust-excluding gaiters. The fore axle is a high-grade steel forging and has a special form of oil-retaining swivel, and in this and other respects the layout is designed for easy steering.

There are two brakes, the one being behind the gearbox and the other (a pair) within the rear wheel hubs. The shoes are interchangeable and measure 15 in. in diameter.

The frame is of channel section pressed steel of extra depth and is cross-tied by tubes secured in suitable socket flanges. The fore suspension is on flat leaf springs and the rear is on flat cantilever type leaf springs. The before-noted special self-lubricating means in this connection need only be recalled. The wheels are of steel and detachable and shod with 820 mm. by 120 mm. tires (nom. 32 in. by 4¾ in.).

The wheelbase and track measure 10 ft. by 4 ft. 8 in. There is a minimum ground clearance of 10 in., and the frame is 20 in. from the ground. The chassis has a gross weight of 1344 lb. It is interesting to note that only two sizes of bolts and nuts and two diameters in ball bearings are used.



New Arrol-Johnston car, the chassis of which is suggestive of American practice. The sales price is $3,500

King-Bugatti 16-Cylinder Aero Engine

PART II

Consists Virtually of Two 8-Cylinder All-in-Line Engines Mounted on a Common Crankcase and Geared to a Common Propeller Shaft—Designed to Permit a 37-Mm. Cannon to Shoot Through Hollow Propeller Shaft

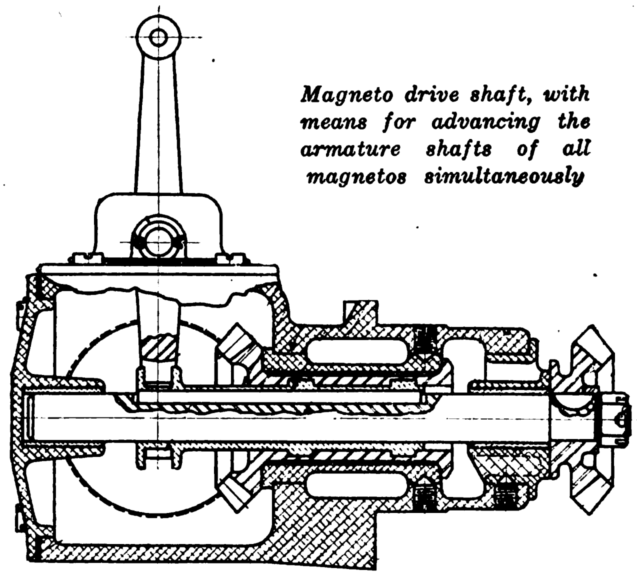
FOUR specially designed Miller carbureters are used, each supplying one block of four cylinders through separate water-jacketed manifolds. They are set low so that gravity feed may be used.

The throttle valve is of the barrel type. the axis of all valves is parallel with the center line of the engine, the two carbureters on each side of the engine being operatd by one shaft which is connected to the valves at each end through adjustable couplings. The shafts on the two sides of the engine are connected so that all four valves move in unison, the valve opening being synchronized by means of the adjustable couplings.

Gasoline is drawn into the jet through the small hole in the bottom of the threaded end, mixing with a certain amount of air sucked in through the four holes drilled in the barrel of the jet just above the threaded portion. This air is taken from the outside through the upper 3/16-in. hole in the jet holder and passes down around the outside of the jet to the four holes mentioned above. The major portion of the air enters the carbureter through the lower end of the venturi, which is 3 in. in diameter, passes up around the jet bar holder, combining above this with the rich mixture from the jets to form the proper mixture for combustion.

Assembly of the altitude valve is shown. This valve operates by turning a lever which is attached to the altitude control valve. This valve has two openings in its seat, which when in the open position register with two similar openings in the stationary cover, thus making two free passages to the outer air.

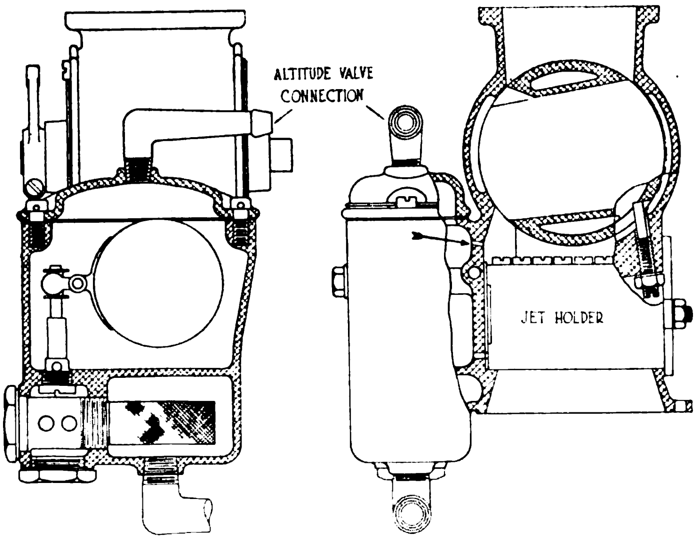
There are four outlets, one of which connects to each of the four elbows, opening directly into the top of the float chamber. The float chamber is always in direct connection with the venturi through a 5/64-in. drilled hole opening into the venturi about ¼ in. above the jet holder and into the float chamber well above the gasoline level. Opening the altitude control valve decreases the vacuum in the float chamber, thus increasing the flow of gasoline through the jets.



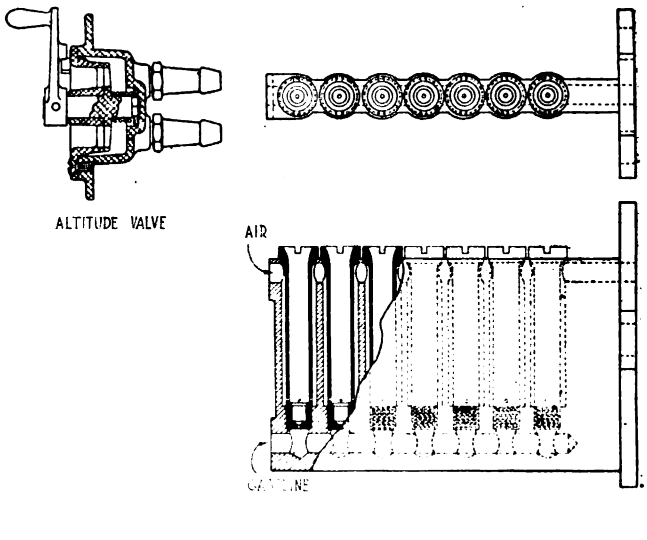
Magneto drive shaft, with means for advancing the armature shafts of all magnetos simultaneously

Ignition is by four Dixie 800 magnetos, two on each side of the engine, driven from the vertical camshaft driving shaft by bevel gearing. All magnetos turn clockwise. Two Titan A-C spark plugs are used per cylinder, located in the side of the combustion chamber.

The rear magneto on the right-hand side supplies current to the rear plug in each of the eight left-hand cylinders, the front magneto on the right-hand side supplying current to the front plug in each of the eight right-hand cylinders. The same arrangement is followed with the magnetos on the left-hand side, so that the two magnetos in either side will fire all sixteen cylinders. Magnetos are set for a maximum advance of 38 deg.



Two sectional views of Miller carbureter



Detail of altitude control valve and multiple nozzle

The bevel gear on the magneto shaft is fitted on a taper with a key. The gear has eight keyways, six spaced 48 deg., one spaced 42 deg. and one spaced 30 deg. This in combination with the gear teeth allows the magneto to be set within 1⅛ deg. on the crankshaft.

The magneto advance and retard mechanism is shown in one of the illustrations.

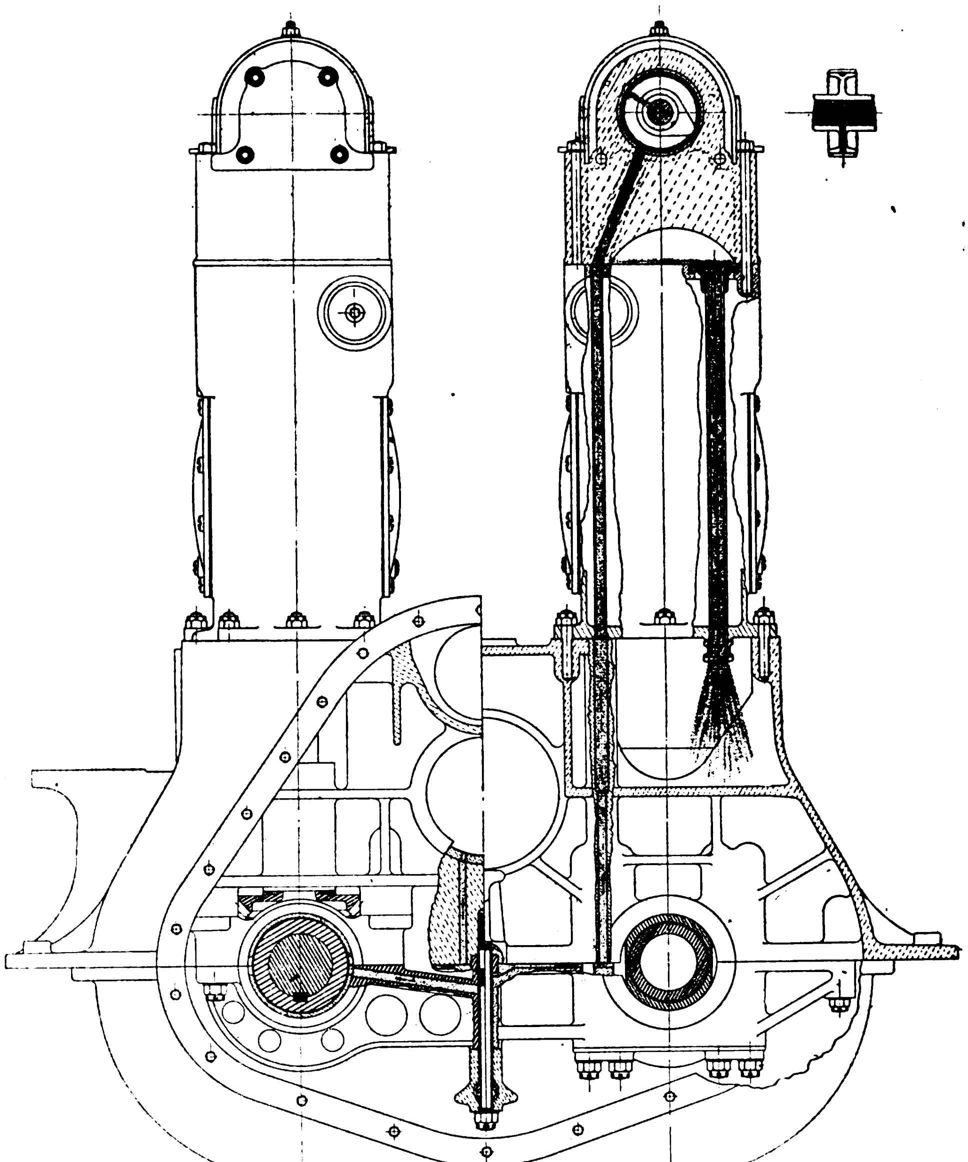
The bevel gear within the housing meshes with the gears on the magneto shafts. This gear has four internal helical grooves sliding over splines on a sleeve which is keyed to the driving shaft but may be moved along the shaft by a lever. The movement of this sleeve revolves the magneto driving gear in relation to the shaft driven directly from the crankshafts cut, thus advancing or retarding the magnetos. The levers on the two sides of the engine are operated from one shaft located above the crankcase between the cylinder blocks, the connections to the levers being through adjustable yokes so that the magnetos may be synchronized.

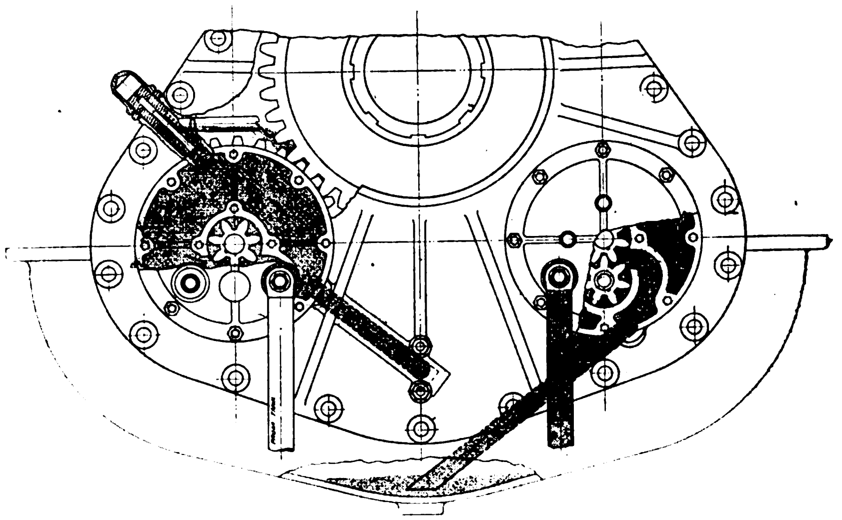
Oiling System

Oiling is by means of pressure feed and spray. There are one pressure and one scavenging pump, both of the gear type. These are located at the front of the engine, driven directly from the crankshafts through a pin and slotted coupling. This coupling is squared to the pump shaft, but is not pinned, thus relieving the shaft of any end driving pressure. The gears in both pumps are the same, except that the scavenging pump gears have a wider face.

Oil, after passing through a strainer, is drawn from the supply tank by the pressure pump, which is driven from the right-hand crankshaft. This oil is forced into the pressure line running the entire length of the crankcase. An adjustable pressure-regulating valve is located in the crankcase front gear cover. It is of the poppet valve spring-seated type and discharges the excess oil directly onto the propeller shaft driving gears. This valve is generally set so that the pressure gage, which is connected to the rear end of the main oil line in the crankcase, registers about 30 lb. This valve has holes drilled through the head so that there is always a certain amount of oil discharged onto the gears.

From the pressure line the oil passes up around the studs which hold this line in position to an oil passage cut along the top surface of the crankshaft bearing cap. For the center crankshaft bearing this oil is carried through a drilled hole. These passages carry the oil to all the main crankshaft bearings. All the main crankshaft bearings





Sketches showing details of lubrication system

Weights, Dimensions and Other Data of King-Bugatti Engine

GENERAL DATA

Material of cylinders	Cast iron
Bore	4.33 in. (110 mm.)
Stroke	6.3 in. (160 mm.)
Stroke—bore ratio	1.455 : 1
Area of one piston	14.725 sq. in.
Total piston area	235.6 cu. in.
Swept volume of one cylinder	92.768 cu. in.
Displacement of motor	1484.288 cu.in.
Compression ratio	5:1
Normal brake horsepower	410 at 2000 r.p.m.
Ratio propeller to crankshaft speed	.666 : 1

VALVES

Number per cylinder	Two inlet and one exhaust
Outside diameter, inlet	1.535
Outside diameter, exhaust	2.263
Port diameter, inlet	1 27/64 in.
Port diameter, exhaust	2 3/64 in.
Width of seat, inlet	.057 in.
Width of seat, exhaust	.108 in.
Angle of seat	10 deg.
Valve lift, inlet	.653 in.
Valve lift, exhaust	.700 in.
Diameter of stem, inlet	.357 in.
Diameter of stem, exhaust (large)	.591 in.
Diameter of stem, exhaust (small)	.4355 in.
Length of vave, inlet	5 17/64 in.
Length of valve, exhaust	5 13/32 in.
Length of spring in position, inlet (small)	2 7/64 in.
Length of spring in position, inlet (large)	2 15/64 in.
Length of spring in position, exhaust (small)	2 27/64 in.
Length of spring in position, exhaust (large)	2 27/64 in.
Main diameter of coils, inlet spring (small)	57/64 in.
Main diameter of coils, inlet spring (large)	1 9/32 in.
Mean diameter of coils, exhaust spring (small)	1 9/32 in.
Mean diameter of coils, exhaust spring (large)	1 23/32 in.
Clearance valve stem	.015 in.

CYLINDERS

Overall height of cylinders	10 27/64 in.
Length of projection in crankcase	3 1/16 in.
Width of cylinder casting at head over water jacket space	5 7/16 in.
Width of cylinder casting at barrel over water jacket space	5 1/16 in.
Length of cylinder casting over water jacket	19 5/32 in.
Thickness of flange (base)	7/16 in.
Number of studs per block of four cylinders	20
Diameter of stud	5/16 in.
Thickness of water jacket side wall and head	5/32 in.
Thickness of combustion chamber wall	13/64 in.
Thickness of cylinder barrel, above flange at water jacket	3/16 in.
Thickness of cylinder barrel, above flange below water jacket	7/32 in.
Thickness of cylinder barrel below flange	9/64 in.
Thickness of valve ports	5/32 in.
Diameter of port at valve, inlet	1 27/64 in.
Diameter of port at valve, exhaust	2 3/64 in.
Inlet port at flange (for two cylinders)	2 9/32 x 1⅜ in.
Exhaust port at flange (for one cylinder)	2 3/64 x 1 31/64 in.
Number of spark plugs per cylinder	2

PISTONS

Material	Aluminum
Length of piston	4 1/16 in.
Length to diameter ratio	.938 : 1
Position of rings	Above gudgeon pin
Width of rings	⅛ in.
Width of land	¼ in.
Distance from bottom to center of gudgeon pin	2 1/6 in.
Thickness of head at center	¼ in.
Thickness of head at edge	⅜ in.
Thickness of wall at bottom	⅛ in.

GUDGEON PIN

Diameter of gudgeon pin	1 5/64 in.
Thickness of wall	.164

CONNECTING ROD

Type	Plain
Length between centers	10 7/16 in.
Ratio length to crank throw	3.313 : 1
Small end bearing	Bronze bushing
Outside diameter of bushing	1 3/16 in.
Length of bushing	2 3/32 in.
Length of small end of rod	2 3/32 in.
Outside diameter small end of rod at end	1 11/32 in.
Outside diameter small end rod at center	1½ in.
Type of section	Eye
Depth (small end)	1¼ in.
Depth (large end)	1 7/32 in.
Width	⅝ in.
Thickness of web	5/32 in.
Thickness of flange (small end)	5/32 in.
Thickness of flange (large end)	13/64 in.
Large end bearing	Bronze babbitt lined
Inside diameter bushing	2 3/16 in.
Outside diameter bushing	2½ in.
Length	2 9/64 in.
Thickness of babbitt	3/64 in.

CRANKSHAFT

Number of crankshafts	2
Number of bearings (plain)	9
Number of bearings (ball)	1
Cylinder centers (in block)	4 17/32 in.
Cylinder centers (between blocks)	15/32 in.
Crank pins (outside diameter)	2 3/16 in.
Crank pins (inside diameter)	1⅛ in.
Length	2 11/64 in.
Main Bearings—	
Outside diameter, Nos. 1, 2, 3, 4, 6, 7, 8, 9	2 3/16 in.
Outside diameter, No. 5	2⅝ in.
Inside diameter, Nos. 1, 2, 3, 4, 6, 7, 8, 9	1⅛ in.
Length, Nos. 1, 2, 3, 4, 6, 7, 8 bearing bushings	1 9/16 in.
Length No. 9 bearing bushing	2 19/32 in.
Length No. 5 bearing bushing	1 31/32 in.
Ball Bearing—Hess-Bright Monarch No 6211	
Crank webs	
Width	3 17/32 in.
Thickness	43/64 in.
Radius of fillets	3/32 in.
Weight of one complete shaft	96½ lb.

CAMSHAFT

Diameter of shaft	1 in.
Inside diameter	11/16 in.
Number of bearings	10
Diameter of bearings Nos. 1 and 10	1 in.
Diameter of bearings Nos. 2, 3, 4, 5, 6, 7, 8, 9	2¼ in.
Length of bearings Nos. 1 and 10	1 5/16 in.
Length of bearings Nos. 2, 4, 7, 9	⅝ in.
Length of bearings Nos. 3 and 8	¾ in.
Length of bearings Nos. 5 and 6	27/32 in.
Width of cam face	5/16 in.
Number of cams per cylinder	3

CAMSHAFT BEVEL GEAR

Pitch diameter	3¾ in.
Number of teeth	30
Pitch	8
Width of face	¾ in.
Diameter of bolt circle	1 23/32 in.
Number of bolts	6
Diameter of bolts	5/16 in.

CAMSHAFT HOUSING

Material	Aluminum

CAMSHAFT DRIVING SHAFT

Diameter	¾ in.
Wall thickness	⅛ in.

CRANKCASE UPPER HALF

Material	Aluminum
Thickness of wall	3/16 to 5/16 in.
Thickness of supporting flange	⅜ to 7/16 in.
Center distance of motor support bolts	24¾ in.
Number of motor support bolts	12
Diameter of motor support bolts	⅜ in.
Center to center of crank shafts	10¼ in.
Height of case	9.055 in.

CRANKCASE LOWER HALF

Material	Aluminum
Thickness of wall	3/16 in.

LUBRICATION

Type	Forced feed and spray
Type of pump	Rotary gear
Number of pumps	One pressure, one scavenging
Oil pressure	30 lb.

PRESSURE PUMP

Number of teeth	7
Pitch	6
Outside diameter	1½ in.
Width of face	13/16 in.
Ratio of pump speed to crankshaft speed	1 : 1

SCAVENGING PUMP

Number of teeth	7
Pitch	6
Outside diameter	1½ in.
Width of face	1¼ in.
Ratio of pump speed to crankshaft speed	1 : 1

IGNITION

Type	Magneto
Number	4
Make	"Dixie 800"
Firing order	1L, 7R, 5L, 4R, 3L, 8R, 7L, 2R, 4L, 6R, 8L, 1R, 2L, 5R, 6L, 3R, 6L, 3R.
Number of plugs per cylinder	2
Type of plug	Titan A. C.
Advance	38 deg.
Magneto rotation	Clockwise

COOLING SYSTEM

Type	Water cooled
Pump	1 Centrifugal
Inside diameter of inlet and outlet elbow to cylinders	1½ in.
Number of inlets	2
Number of outlets	2
Water temperature inlet	150° F.
Water temperature outlet	160° F.

WATER PUMP

Material	Aluminum
Inside diameter of inlet	2¼ in.
Inside diameter of outlet	2 3/16 in.
Diameter of impeller	5⅞ in.
Number of blades	8
Ratio pump speed to crankshaft speed	1 : 1

REDUCTION GEARS

Crankshaft Propeller Drive Gear—	
Pitch diameter	5.6 in.
Pitch	5
Number of teeth	28
Width face	2⅜ in.
Diameter bolt circle	3 17/32 in.
Number of bolts	9
Diameter of bolts	7/16 in.
Propeller shaft gear:	
Pitch diameter	8.4 in.
Pitch	5.0 in.
Number of teeth	42
Width face	2⅜ in.
Number of splines	8
Width of splines	.405
Height of splines	.094

PROPELLER SHAFT

Number of bearings	3
Type of bearings	Two ball; one plain
Ball bearings	No. 6219, special width, Hess-Bright
Plain bearing	Bronze babbitt lined
Diameter of bearing	3 7/16 in.
Length of bearing	1½ in.
Thickness of babbitt	1/32 in.
Outside diameter at gear (over splines)	3¾ in.
Outside diameter at rear end	3 5/16 in.
Outside diameter at propeller	3 31/64 in.
Inside diameter	2 61/64 in.
Diameter propeller flange	9¾ in.
Thickness flange	7/16 in.
Thickness loose flange	9/32 in.
Length of bearing loose flange on shaft	¾ in.
Diameter of bolt circle	7¾ in.
Diameter of bolts	⅝ in.
Number of bolts	8

Engine full throttle horsepower and propeller horsepower

and pins are hollow. All even-numbered main crankshaft bearings have a 3/16-in. radial hole drilled entirely through them. All the crankpin bearings have a 3/16-in. radial hole drilled from the inside to the central hole. A 13/64-in. hole is drilled in the web, both sides of even-numbered main crankshaft bearings connecting the central hole in the main and pin bearings. A copper shell is placed in these central holes and the ends are spun over, making an oil-tight joint. These shells are necked in the central portion so that a tubular oil space is left.

Oil from the passages in the crankshaft bearing cap is forced into this tubular oil space through the 3/16-in. holes which register with this passage twice per revolution. From here the oil passes to the pin bearings, the leakage from these bearings being thrown on the cylinder walls and piston pins, thoroughly lubricating these parts.

Four vertical holes are drilled in the crankcase web connecting with the oil passages in crankshaft bearing caps Nos. 3 and 7. These holes register at the top of the crankcase with copper tubes which pass through the cylinder water jacket space, registering at the top of the cylinder block with four holes drilled in the webs of the crankshaft housing. These holes register with an oil groove of 3/64 in. radius cut entirely around camshaft bearings Nos. 3 and 8, right and left. A No. 35 drill hole connects the oil grooves with the interior of the hollow camshaft. Oil is thus carried under pressure to the hollow camshaft. From the hollow camshaft the oil passes to camshaft bearings Nos. 1, 2, 4, 5, 6, 7, 9 and 10 through a No. 35 drill hole. Camshaft bearing bushings Nos. 2, 4, 7 and 9 have a 3/32 in. by 1/32 in. oil groove cut full length of the bearing surface, the drilled hole in the camshaft bearing registering with this groove once per revolution, causing a small stream of oil to shoot out both sides of the bearing, thoroughly lubricating the cams, valve rocker shaft, rollers and valve stems. Camshaft bearing bushings Nos. 5 and 6 have a 3/32 in. by 1/32 in. oil groove cut from ¼ in. of the outer edge to the inner edge, the drilled hole in the camshaft registering with this groove once per revolution. Oil from this groove in the rear bearing lubricates the thrust surface of the camshaft bevel gear, while the small stream from the front bearing thoroughly lubricates the camshaft and camshaft driving gears and the camshaft driving gear bearings.

A 3/16-in. hole is drilled in the crankcase web connecting with the oil groove in No. 6 crankshaft bearing cap and registering with a 1/16-in. drilled hole in the propeller shaft rear bearing bushing. This thoroughly lubricates this bearing. The oil flowing from this bearing returns to the sump by gravity.

The camshaft and magneto driving gears in the crankcase are lubricated by spray. The gearing in the camshaft housing is packed in grease. The crankshaft and propeller shaft ball bearings are lubricated by spray. Oil which drains to the bottom of the camshaft housing is returned by gravity to the crankcase through twelve pipes passing through the cylinder water jacket space. Oil which drains to the front end of the sump is returned to the oil tank by the scavenging pump. Oil which drains to the rear end of the sump is returned to the oil tank by gravity.

Cooling System

Cooling water is circulated through the engine by means of a centrifugal pump, driven from the rear end of the left-hand crankshaft by a pin and coupling, the same as used on the oil pump.

The cooling system from the pump inlet to the outlet elbows on the front cylinders holds 4¼ gallons of water. The pump impeller is 5⅞ in. in diameter, with eight vanes, the web being drilled with eight ⅝-in. holes on a circle of 2 in. diameter to equalize the water pressure.

The pump shaft is packed with a graphited asbestos rope packing, automaticlaly held under compression by a coiled spring acting on the gland. The pump shaft is hollow, the rear end being in direct communication with the water in the pump case. Water entering the shaft is forced out to the shaft rear bearing surface through a ⅛-in. hole. Any leakage of water past the asbestos packing is drained outside of the crankcase through a ⅝-in. cored hole in the water pump body.

Fordson Assembly Wholly on Progressive Plan

PART II

Cylinder Block and Transmission Housing Assemblies Travel Along Parallel Lines Until Complete—Two Lines of Complete Tractor Assembly

By J. Edward Schipper

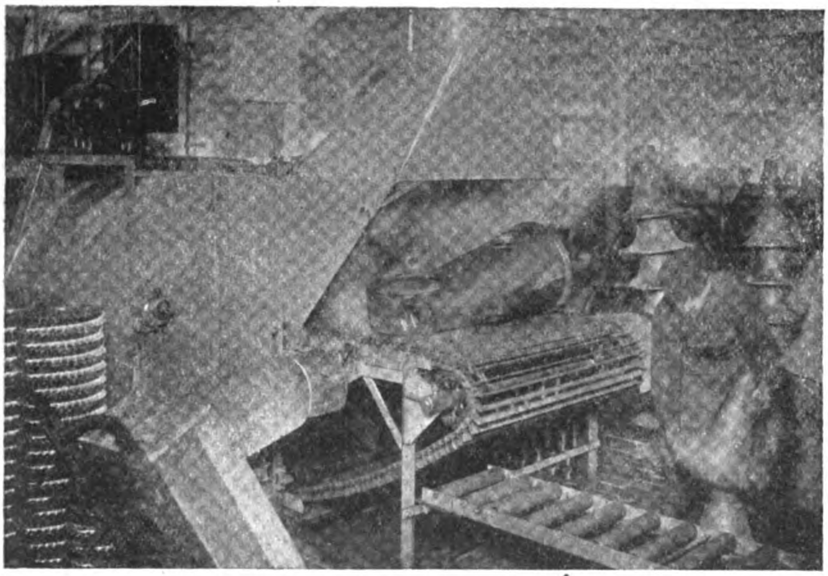

Fig. 14—Beginning the assembly of the transmission and rear axle. The roller conveyor comes from the manufacturing department, and the first operation is that of washing

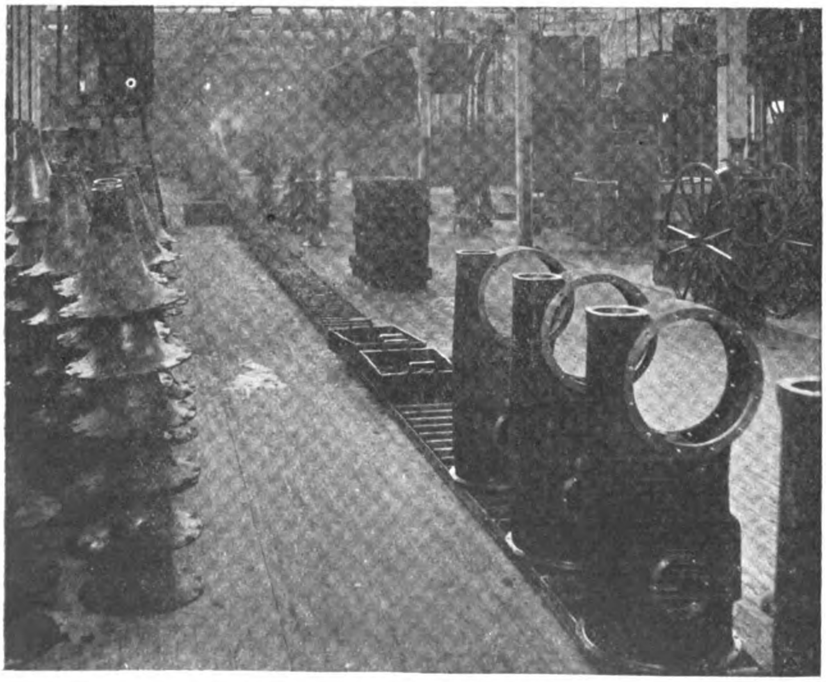

Fig. 15—Looking backward toward the washing machine, showing the incline down which the parts slide to the beginning of the transmission assembly track

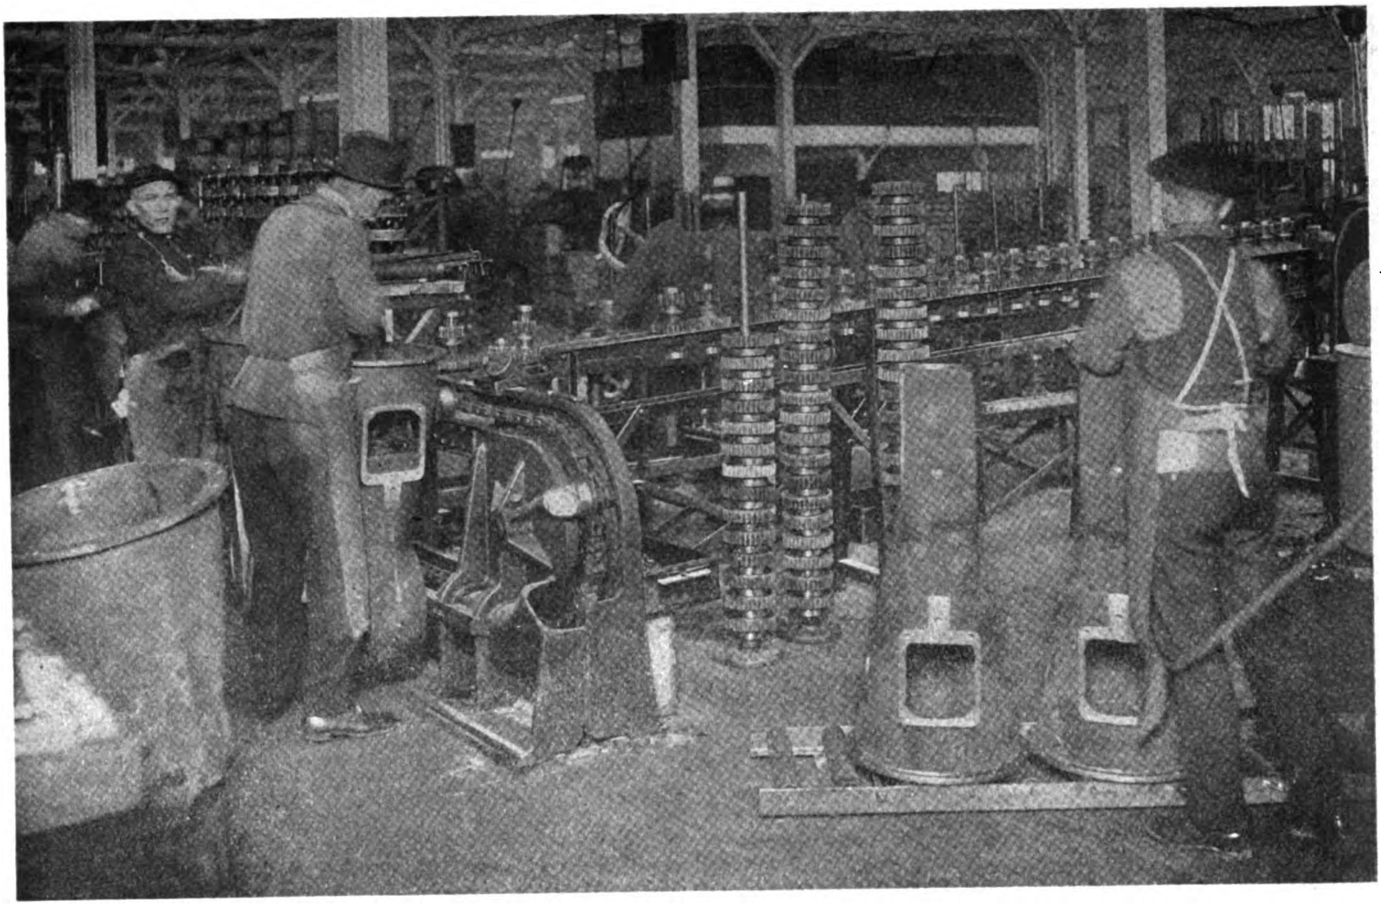
ALL the large castings and heavy parts used in the assembly of the transmission and rear axle which are in any way likely to be soiled or greasy from manufacture are put through the large washing machine shown in Fig. 14. In this illustration one of the big castings used as the body of the Fordson tractor, and which houses the transmission and rear axle gears, may be seen starting through the washing machine. The operator is just lifting up a rear axle housing from the gravity conveyor from the manufacturing department ready to put this through the washing machine, and thus the heavy parts all pass through as indicated.

The way they leave the washing machine and run down a slope to bring them to the assembly line is seen clearly in Fig. 15, which is looking back toward the washing machine. The slope is apparent in the background, and as the different parts come down the line they are picked off the gravity roller conveyors and put in proper position for assembly. The rear axle housings have gained a little, and are shown here stored. The two pans on the conveyor contain small parts which have been washed.

As will be noted in Fig. 15, the large castings are allowed to remain on the conveyor, and, as a matter of fact, everything is timed according to these. They pass along the conveyor and reach the foot of the slope at the point shown in Fig. 16, which is the commencement of the transmission assembly chain.

One of the hooks upon which the transmission housing is caught up has just come around on the track wheel, and is apparent in the foreground of the photograph. The gears which are ready for assembly, and which have been previously assembled on their shafts by means of arbor presses, come down on the sloping carrier to the assembly tracks. The men only work on one side of this track. Transmission gears are assembled in place with the casting vertically held by the hook on the conveyor chain, hence the operator can drop them into place without excessive effort, and the hook carries the casting along in this position.

After the completion of all assembly work which can be done with the casting in an upright position, there is a turnover carrier



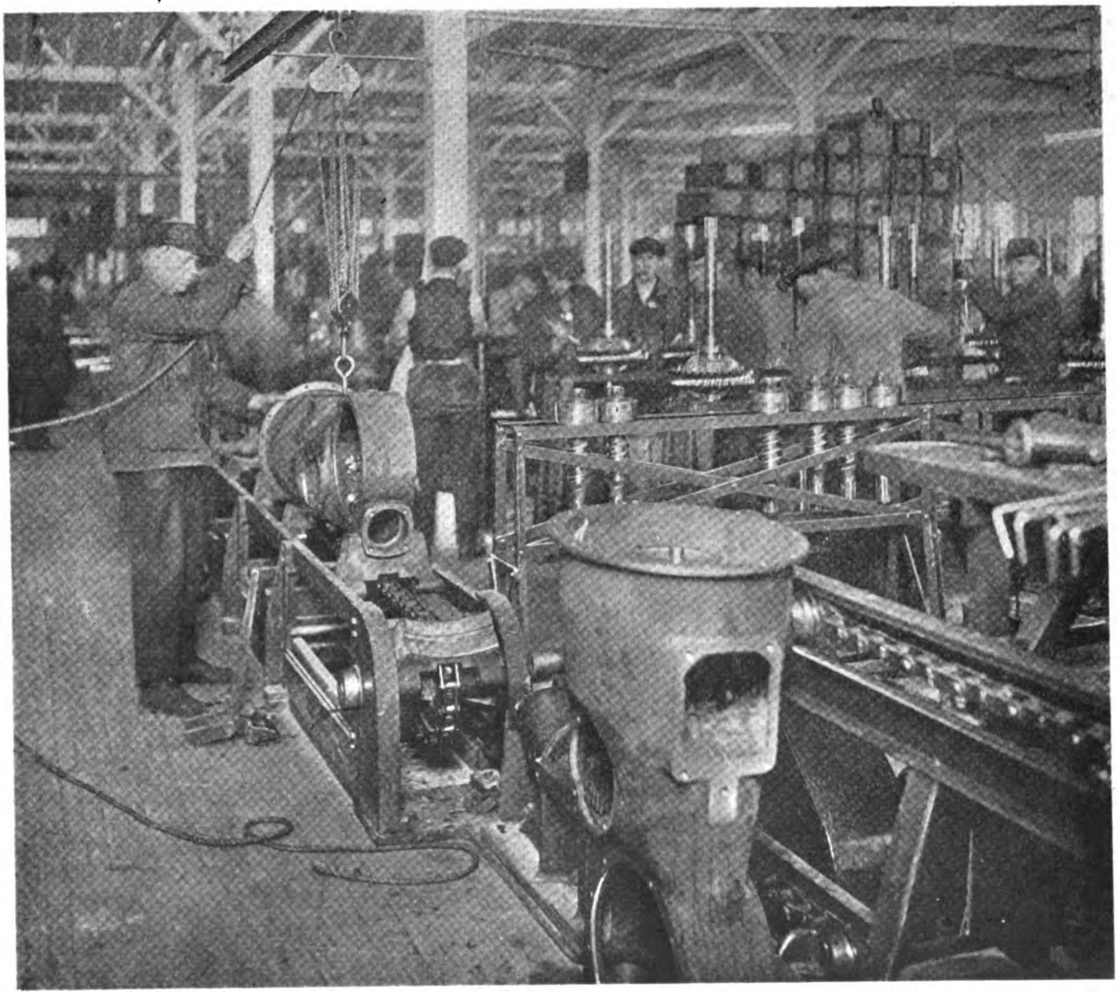


Fig. 16 — Looking ahead at the beginning of the transmission and rear axle assembly. Note the hooks on the chain which pick up the transmission housing and note the carriers from the arbor pressing department carrying the shafts with the gears in place

Fig. 17 — When the first assembly operations are complete, with the transmission housing in a vertical position, they turn over horizontally to the next section of the transmission assembly chain. This view shows the housing just about ready to turn over, and one is turned over in the background. Also in the background can be seen the preliminary sub-assemblies on the worm shaft and rear axle

Fig. 18—Section of the transmission housing assembly track, showing how the men work on both sides and how the nuts and bolts are carried in pans beneath the track. The bearings and bearing cases are held in containers close to the track Men are working on both sides of this track, performing symmetrical operations

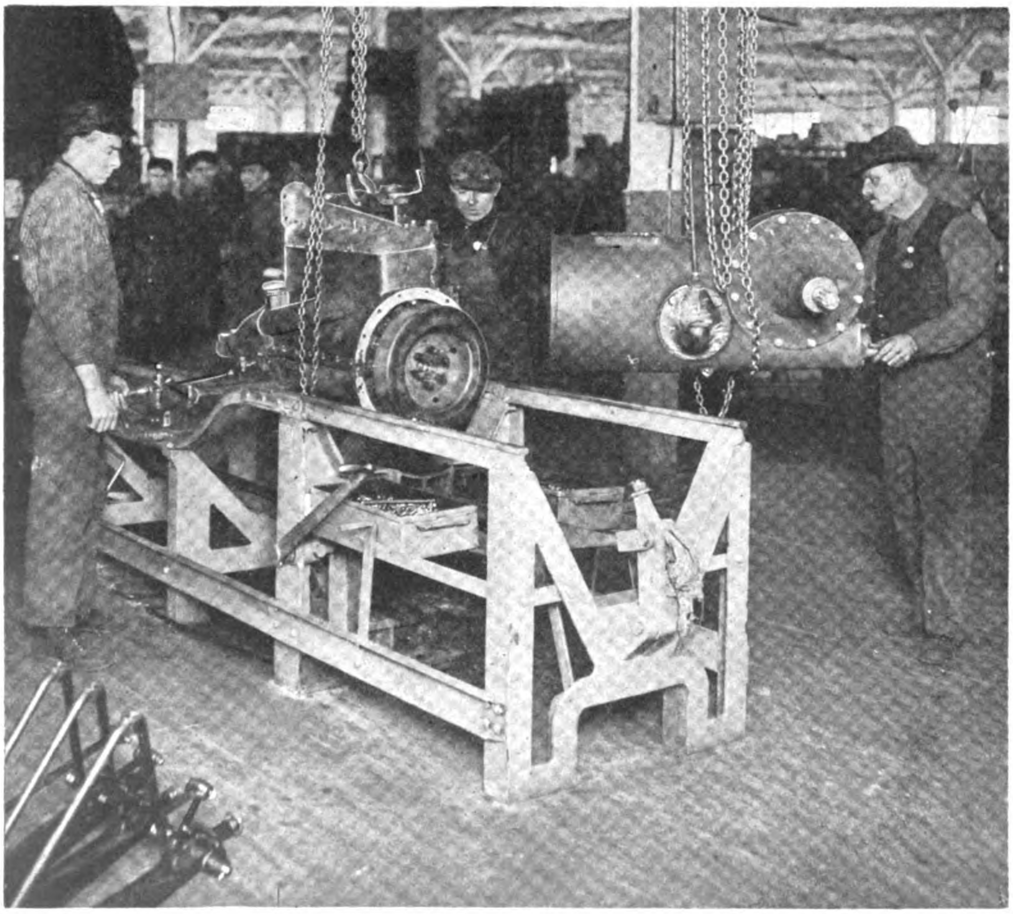

Fig. 19—When the completed transmission housing assembly reaches the end of the chain it is swung over to the beginning of the tractor assembly track. This starts out with a stationary stand upon which the halves are first bolted together before they are pushed down an incline and enter upon the moving track

which allows the casting to swing over horizontally. As shown in the foreground of Fig. 17, there are no intermediate steps between the vertical position and the horizontal position of the large transmission housing. It is immediately turned over on its side. The first operation to take place when in this position is to put in the final drive parts, including the worm shaft, worm wheel, etc. In the background of Fig. 17 may be noted the parts for the final drive coming down on the sloping racks utilized as feeders to the transmission chain.

On the transmission assembly, men are working on both sides of the chain in the same way as on the engine assembly, and it is interesting to note the storage beneath the chain of the necessary bolts, nuts, soft hammers, etc., for the operations performed above that point. Fig. 18 shows this very clearly, the pans beneath the track being continually filled by men assigned to this duty, who come along with scoops full of bolts, etc., to keep the pans replenished. The axle shafts

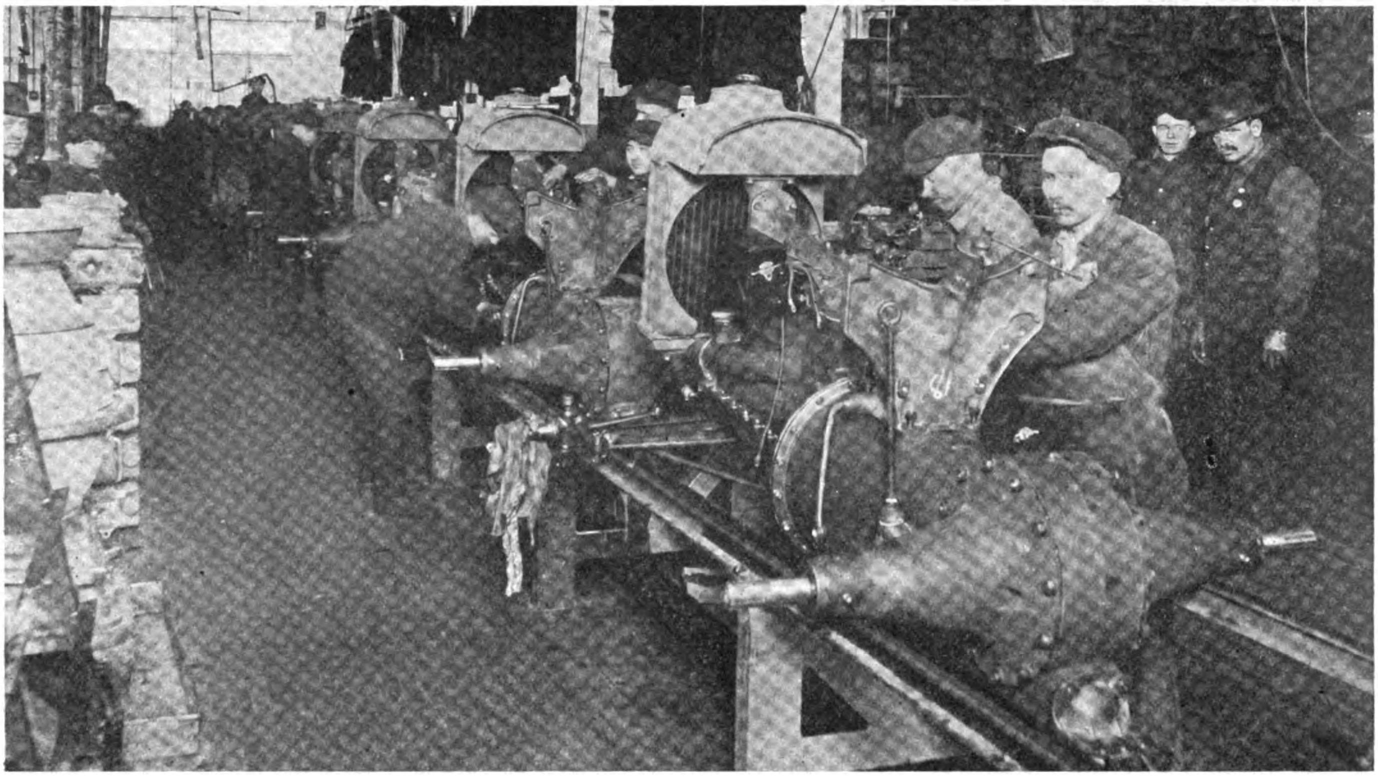

Fig. 20—Tractors moving along the tractor assembly track. In the foreground is a tractor which has just come down the incline and started on the track, and way in the background can be seen the open door through which the finished tractors leave the building

are shown here in position, and the next step, a little further on, is also seen in Fig. 18, which is putting on the rear axle housing. When this has been completed the transmissions are finished and are ready to be carried over to the beginning of the tractor assembly chain.

Final Tractor Assembly

An overhead crossover accomplishes this work. There are two tractor assembly chains and the finished transmissions and engines are fed alternately from each of the single engine and transmission lines to one of the tractor assembly chains. Fig. 19 shows the stand at the end of one of the tractor assembly chains ready to begin its journey down the final assembly tracks. This stand is stationary. One man brings the engine over, another the transmission, while men at the stand are ready to bolt the flanges together. While this is going on the coil box is brought over and mounted on the side of the engine. To the

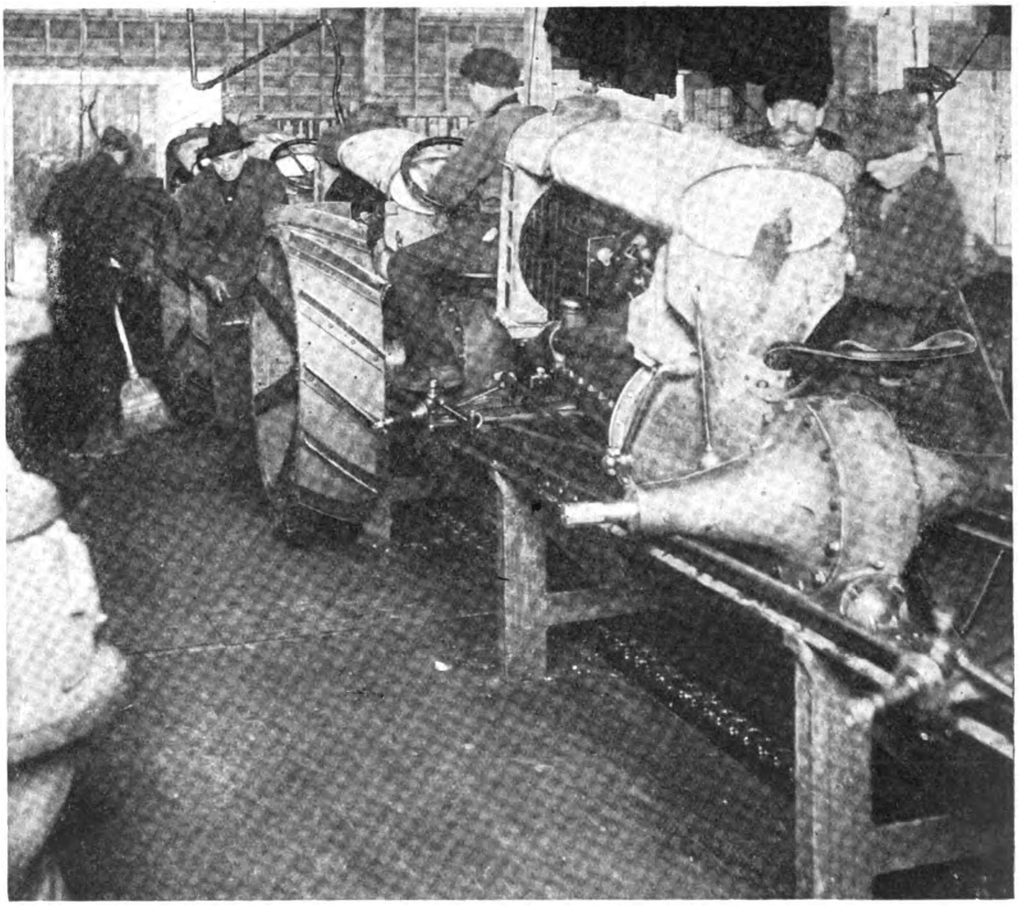

Fig. 21—The end of the tractor assembly chain, at which end the wheels and accessories are put on and oil, gasoline and water put in place so that the tractor can be started. In the background is seen a tractor with its wheels in position

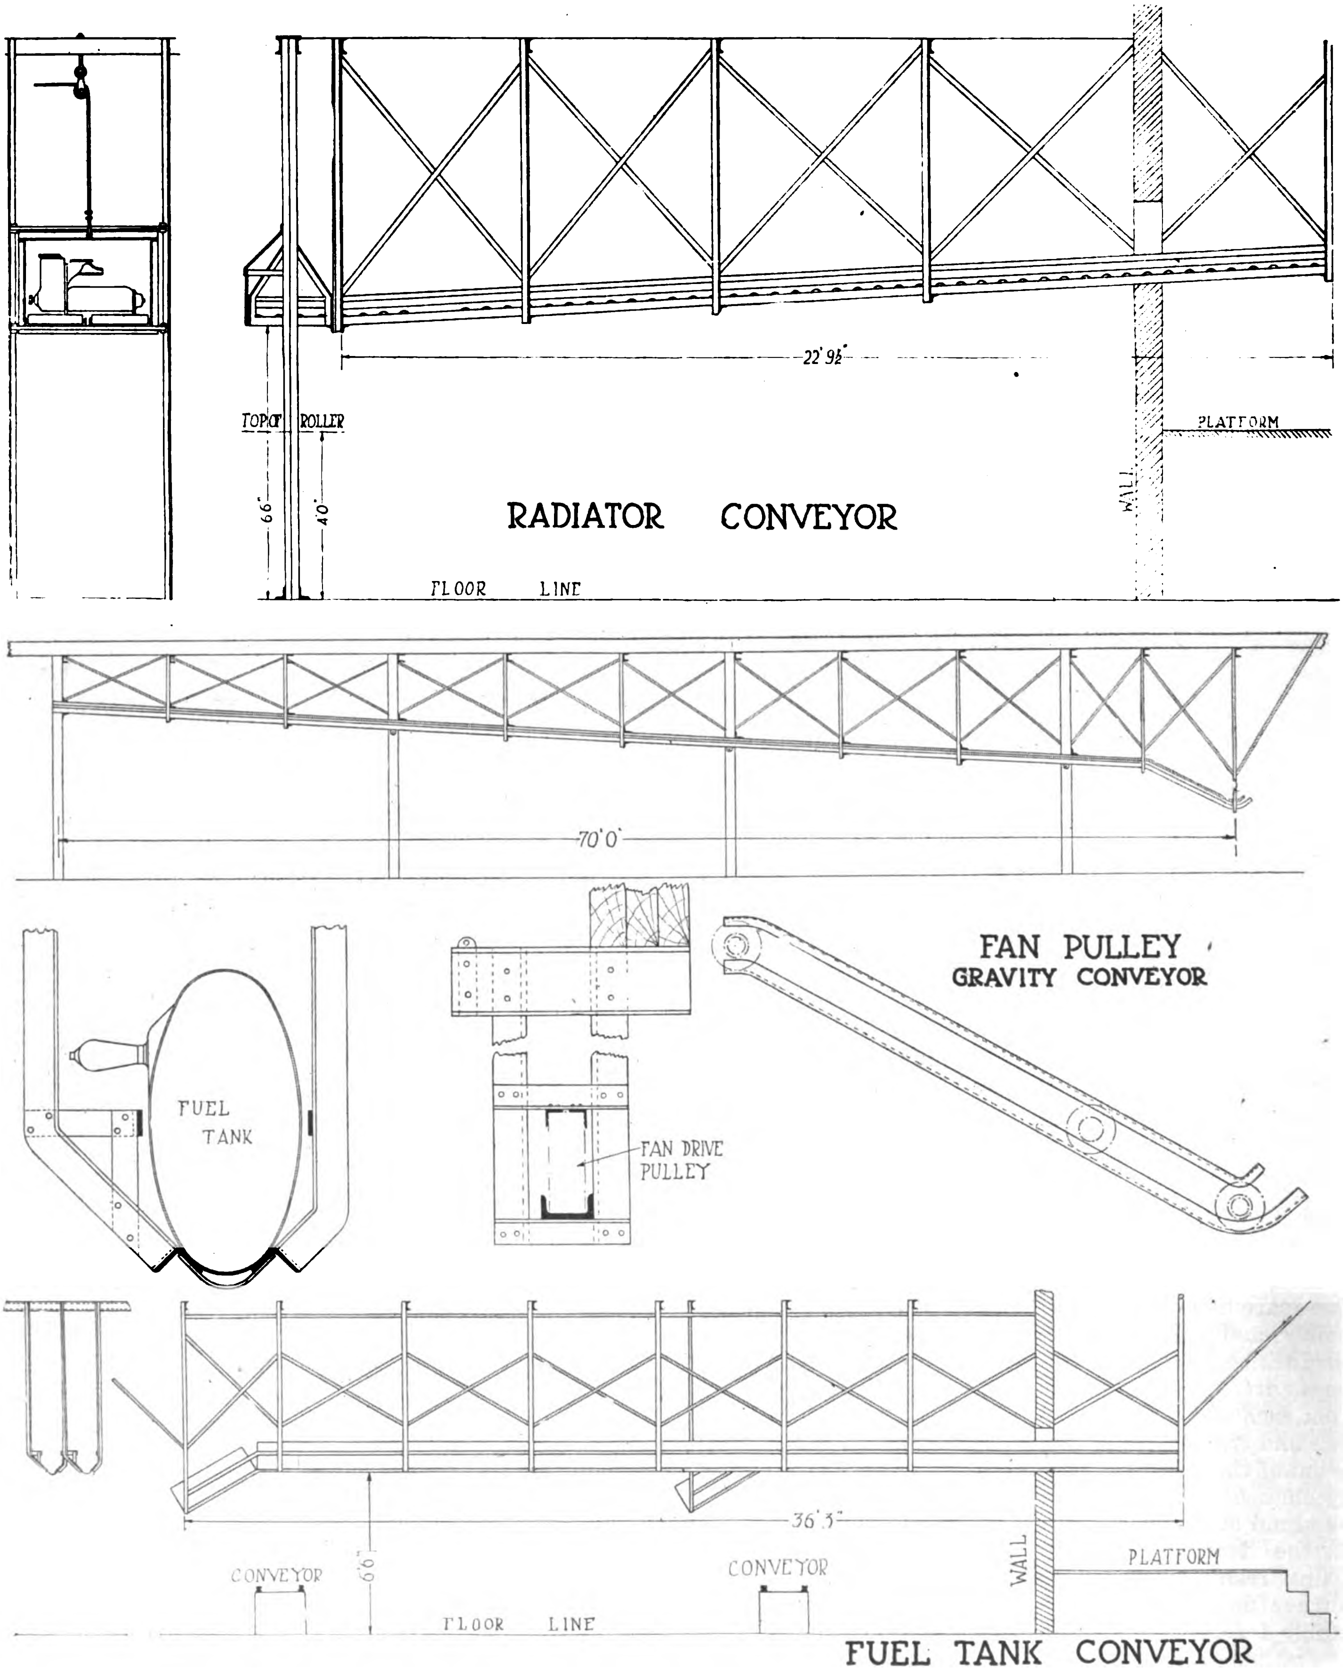

Overhead Conveyors Used in Assembling the Fordson Tractor

The upper one for the radiator is of the gravity roller type and is provided with a counter-balanced elevator at the end, which automatically drops the part to a convenient height for the workman. On removing the radiator the elevator returns for the next one.

Small circular parts such as the fan pulley are rolled between two sloping channel irons, extending from the machine shop to the assembly department.

The fuel tanks are supplied from outside the building. They slide on two angle irons with guide strips at the side.

Fig. 22—Left—Tractors at the end of the assembly row. Here they are ready to be started. At the left of the illustration is shown the machine for doing it. This is a swinging electrical cranking machine which fits over the starting crank handle. Fig. 23—Right—Electric cranker in position turning over engine while it is receiving water

left of the illustration may be seen one of the men with the coil box ready to bring it to the proper position. The stationary stand at the end of the complete tractor assembly track is slightly higher than the track itself, so that when the flanges are bolted together and the preliminary operations on the stationary rack are completed, it is only necessary to push the tractor down the slope, where it is carried on rails to the track, which picks it up and starts it along for the next operation.

The commencement of this journey is shown in Fig. 20, where a view is given down the line of assembly. The doors seen in the background show where the tractors are finished. The foreground shows the first steps along the moving chain. The radiators are put on, the coil boxes in place, fans, steering gears, control mechanism, tank, steering wheel, etc., go on step

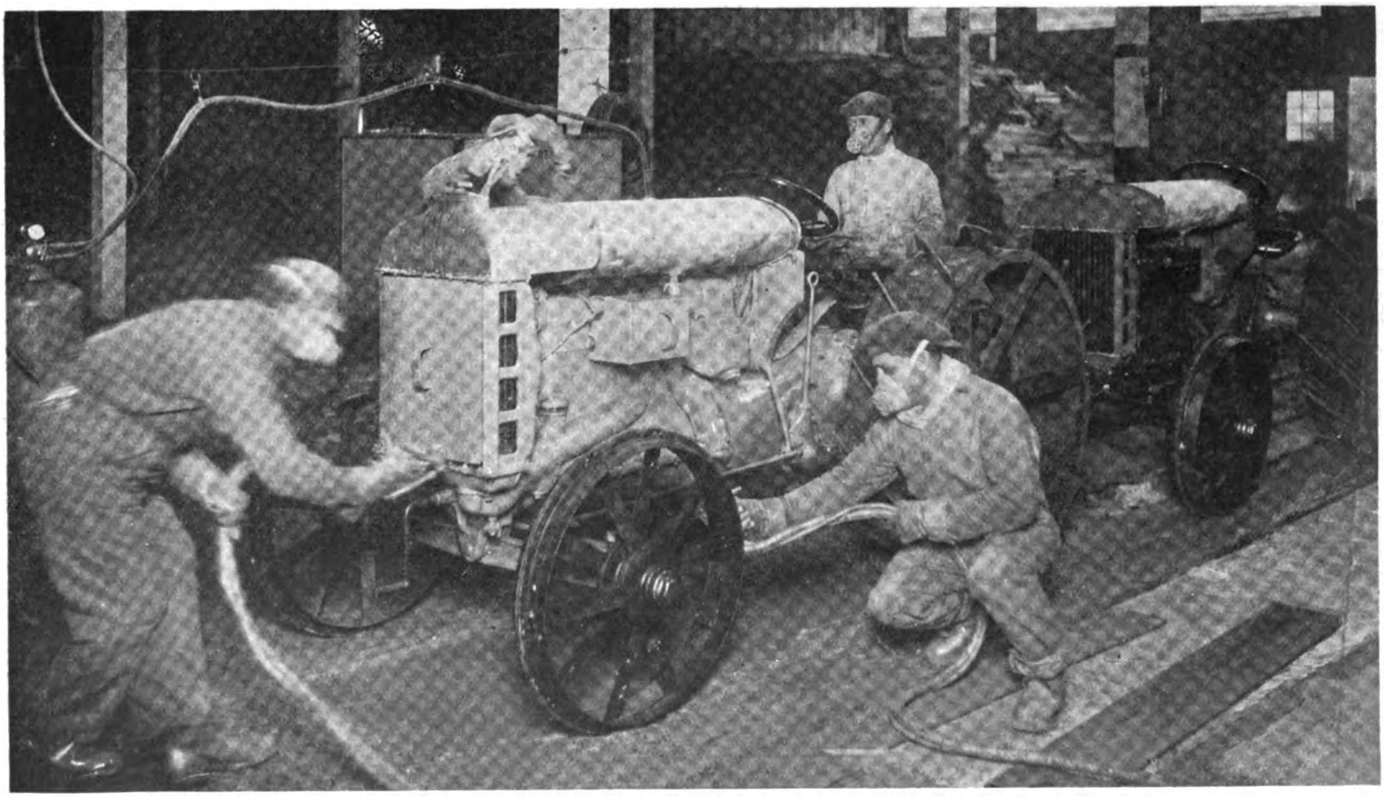

Fig. 25—Tractor in the paint shop being spray-painted by a gang of men wearing gas masks. It takes 2 min. to spray a tractor, and there are two gangs at work

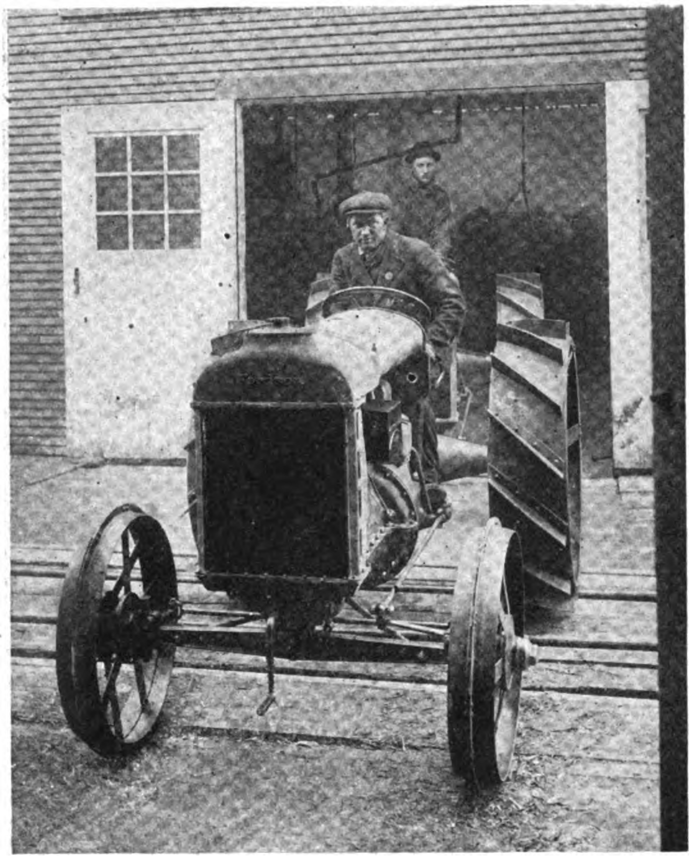

Fig. 24—The finished tractor being driven out of assembly building across a small alley into the paint shop

by step, and the materials are stored always at a point along the chain where they will be required for assembly. Eventually the wheels which go on the tractor will be fed from underground and come up on an elevating conveyor which will bring them directly to the right place. At the present time, as a temporary arrangement, they are rolled in, but this will not last much longer.

Fig. 21 shows the tractor ready for its wheels, and, in the background, a tractor which has its wheels already in position. Here the wheels are bolted tight, the accessories all mounted in position, the radiators filled with water and sufficient gasoline is put in the tank for an ordinary running which the tractors receive immediately after they leave the assembly chain. Fig. 23 shows the tractor immediately after it has left the end of the assembly chain. It is now ready to start, and the device shown at the left of the illustration incorporates a very ingenious method of cranking the engine. This is a beamed-shaped construction with a starting crank, as illustrated. It is swung into the tractor as shown in Fig. 22, and the electric motor started, whereupon the tractor engine is cranked vigorously until firing begins. Timing several of these showed that it required an average of 15 to 18 sec. to start a tractor. As soon as the tractor engine is started a driver-inspector steps into the seat and drives the tractor out of the assembly shop door, as shown in Fig. 24, where it passes across a narrow alley into the paintshop.

The painting is done by two gangs of four men each. These men are equipped with gas masks, and it requires 2 min. for a gang of men to paint a tractor. As soon as the tractors are painted they are driven away.

Wartime Investigations in Wood and Glue

UNDER the stress of war and the necessity of furnishing aircraft to the fighting front in large numbers and in a short time, it was found necessary to supplement the information available on wood and glue by extensive additional research work on these two important construction materials. It was found in many instances that factories taking Government contracts for aircraft and wagon work had in their desire to help neglected to go into the situation thoroughly and found themselves unable to produce on schedule. The rigid Government inspection showed them that their equipment was inadequate to meet the special demands placed upon it, and their knowledge of the peculiarities of the material was not sufficiently exact.

Many varied difficulties were encountered. Vehicle manufacturers had trouble drying stock. Lumber for wagons to be used in the hot, sandy sections required more thorough drying treatment than lumber for wagons to be used in more moist districts, and it was necessary to dry heavy stock quickly. Propeller manufacturers found that making propellers involved a great many more variables than the mere gluing of laminations and shaping the block—internal stresses occurred that caused warping and open joints in seemingly perfect blocks. Though they had been using glues for many years, they soon discovered that there was a wide difference between high-grade laminated work and the class of work ordinarily accepted as commercial standard. It is not surprising that the panel manufacturers making aircraft plywood for the various governments had some little difficulty at first in meeting aircraft specifications.

While waterproof glues have been in existence for some years, they were not well known and little information was at hand as to the correct procedure for their successful use. During the war the Forest Products Laboratory of the U. S. Forest Service at Madison, Wis., has been working on problems that seemed to give trouble to the plants engaged on war contracts. Much help has been given manufacturers, and a large staff of specialists has been engaged in obtaining information and developing new ideas in the uses of glues and wood.

Automobile Standardization in Great Britain

FOR some years there has been a somewhat ambiguous position with respect to automobile standardization in Great Britain. The Institution of Automobile Engineers no doubt wished to emulate our S. A. E. and take charge of this work, but inasmuch as there is an Engineering Standards Committee in Great Britain which is in control of all standardization in connection with mechanical engineering, this was out of the question. An agreement has now been reached between the Institution of Automobile Engineers, the Society of Motor Manufacturers and Traders and the Association of British Motor and Allied Manufacturers, in regard to the future handling of all technical matters connected with the automobile industry and the relations between the industry and the British Engineering Standards Association.

In 1917 the Technical Committee of the Motor Industries was founded by the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders as an administrative body to consider matters in connection with standardization, research, etc., and to co-ordinate investigation in connection therewith. By the arrangement just come to this committee will be disbanded, and the functions exercised by it will in future be carried out by a Technical Committee appointed by the Association of British Motor and Allied Manufacturers. The latter body was formed to look after the commercial interests of the British automobile building firms, and it has agreed to conditions which will insure that the technical qualifications of that committee shall be properly safeguarded.

The FORVM

Advantages of Steam

By Sewall Morse

IN the March 20 issue of AUTOMOTIVE INDUSTRIES Dr. C. P. Schwarz wrote interestingly of the possibilities of steam power from a thermal standpoint. When competition began between the steam engine and the internal combustion engine for supremacy in motor vehicle use, it was claimed that the "gasoline engine" was much the simpler and simpler to operate, besides being far more economical of fuel. Manufacturers of automobiles propelled by gasoline engines, taking advantage of the ignorance of the public in relation to these engines, pointed to the numerous undesirable features of the early steam automobiles and then triumphantly pointed to the new power which was soon to make steam power a matter of history, and announced that "all you have to do is to turn the crank and go." Eventually the manufacturers of steam cars, with one exception, gave up the game. This exception was slow to improve, but to-day it is not only demonstrating, I am informed, that a steam-propelled car can accomplish as much with 1 gal. of kerosene as the average gas car of equal weight does with 1 gal. of gasoline, but is cheaper in maintenance, has few troubles, is mechanically simpler than the gas car, is safer in emergencies and simpler to control.

There is not a low-priced steam car in the market, yet such a car offers no serious problems in its conception. The writer has been informed by men who know the market that there is a big waiting demand for a low-priced steam car, and a salesman of gas cars was recently heard to say that he believed a steam car at $1,000 or less would be the best selling proposition in the pleasure car field to-day. The important advantages of steam power for the propulsion of trucks and tractors are known to all mechanical engineers, and the use of coke, coal or crude oil for fuel is possible. With simplicity, reliability, durability and fuel cost in its favor, does it not seem that motor vehicle manufacturers and others who have the necessary capital are blind to the possibilities offered by steam in the motor-vehicle field?

From a thermal standpoint there are possibilities, both in steam generation and use, that can be utilized, and by means practical for motor vehicle use, that will result in thermal efficiencies at least equal to that of the best automobile gas engines now in use. This statement is made as a result of long study of the many problems relative to the economic generation and use of steam in small power plants and the designing of means for its accomplishment.

Ideal efficiency in the steam engine is first limited by the temperature of the steam that it is practical to use. While this limit is to be regulated for the use for which the outfit is intended, there is positive assurance that an astonishing efficiency can be obtained from steam outfits of 100 hp. and less, that such outfits can be made practical, of low cost and adapted to the use of any liquid or solid fuel. The limit of efficiency, where the highest efficiency is essential, as in aviation uses, would seem to be dependent upon a steam temperature that would permit of cylinder lubrication. However, suitably designed steam engines have been continuously operated with steam at from 800 deg. to over 900 deg. Fahr., and for short periods at higher temperatures, with no resultant injury whatsoever to pistons or cylinders; and it is not unlikely that an engine can be designed that can be successfully operated with steam at any temperature that it is practical to produce. That steam power can be made practical for aerial uses the writer has not a doubt, and that a steam-power plant can be produced that will approximate the light weight and the high efficiency of recent aviation engines there are good grounds for assuming. The possibility of light weight and high efficiency with steam power, with its better condition for reliability and safety, seems to merit greater attention in aviation circles than has, apparently, been given it.

With steam at extreme temperature it must be anticipated that valves will, after a time, score and leak, but a steam engine will operate with leaking valves, although at lower efficiency, and leaking valves can be repaired or replaced; but for motor vehicle use steam of high pressure and a practical superheat can be used with perfect satisfaction, and, with kerosene or crude oil for fuel, with a resultant general economy, combined with reliability, mechanical simplicity and simplicity of control. There are reasons to doubt that this can ever be accomplished with the internal combustion engine.

Cooling Fan Problems

By Louis Schwitzer

President, Automotive Parts Co.

REFERRING to Mr. Hoyt's article on Radiator Cooling Fans, his statements with regard to end thrust are incorrect and the charts showing the amount of it are misleading. Mr. Hoyt states that a fan running in free air will produce a certain end thrust, but when this fan is placed back of a radiator the end thrust is increased about 25 per cent, depending on the restriction of the air passage. It is an established fact and a physical law that the pressure exerted by a moving air column, the end thrust, is a direct function of the air velocity. In other words with the increase of air velocity, the pressure or the end thrust increases. If a fan is placed behind a radiator the air velocity produced by the fan is considerably less than in free air, on account of the restriction. If Mr. Hoyt's contentions are correct, then if the intake were restricted to such an extent that no air could be delivered the thrust load would be infinitely larger. This is absurd.

The charts in Figs. 5, 6, 7 and 8 also show that the end thrust drops faster than the air velocities; in other words, by restricting the inlet the thrust load will be diminished faster than the air velocity. All the curves in Figs. 5, 6, 7 and 8 show thrust loads of fans moving in free air. The manufacturer is interested only to know what thrust loads are produced in a fan behind a radiator, and not in free air or in a wind tunnel.

From actual tests and measurements on nearly 400 different makes of passenger cars, trucks and tractors, the writer has found that on about 80 per cent of these the maximum average air velocities obtained through the radiator are below 1500 feet per minute; on about 17 per cent the velocity is between 1500 to 1900 feet per minute and on only 3 per cent it is above 2000 feet per minute. The highest ever found was 2200 feet per minute. These are the air velocities which must be taken into consideration in determining the thrust loads in radiator fans under actual operating conditions.

It will be found from Mr. Hoyt's chart Fig. 5 that on a 16 in. fan, considering even the maximum obtainable average air velocity of 2000 feet, the thrust load will be not more than 3 pounds. On an 18 in. fan as per Mr. Hoyt's chart, Fig. 6, it will be about 3¼ pounds. For 20 in. and 22 in. fans (Figs. 7 and 8) Mr. Hoyt does not show air velocities as low as the maximum actually obtained with these sizes of fans on automotive vehicles. In Fig. 8 the velocity and end thrust curves start with 2600 feet per minute and a corresponding end thrust of about 6.8 pounds. I do not believe a single truck or tractor can be found where air velocities of 2700 feet per minute through the radiator can be measured. In passenger cars, where this or higher air velocities through the radiator can be produced, it is done at high vehicle speed only. At these speeds, however, the initial air velocities produced by the motion of the vehicle tend to drive the fan and balance the end thrust produced by the fan itself.

In any event, it is shown by charts (Figs. 5, 6, 7, 8) that the thrust loads in radiator fans for the air velocities actu-

Intelligent Governmental Co-operation Needed

THE welfare of American industry should be the chief consideration of the next Congress. The world struggle for commercial supremacy now beginning will be won by that country which extends the most complete and most intelligent governmental co-operation to its manufacturers. This means that Congress must consider every form of governmental aid, financial, legislative, practical and direct, for American industry. It means, if America is going to win, or even hold her own in the great commercial conflict, that there must be a complete removal of the present obstacles thrown in the path of industry by ancient governmental systems.

An automobile manufacturer recently inquired of a government department for important information. The department had about 75 per cent of the data needed. To send them incomplete was useless. To secure the remainder meant an expenditure of a small amount of money. To get approval for the expenditures required 40 days. When the manufacturer was finally given the information it had ceased to be of value.

The fault in this and other similar cases lies in a system which was designed to insure wise and proper expenditures of great sums for battleships and the like, but which, in its inflexibility, reacts harmfully in its application to minor matters.

If governmental departments are to be of benefit to American industry it will be necessary for them to be as keenly awake, energetic, efficient and flexible as American industry itself, else we shall have the equivalent of a huge organization with one-half operating on a modern quantity production basis and the other stifled by antiquated methods.

Employers' Industrial Commission

IN last week's AUTOMOTIVE INDUSTRIES was published a report of the commission which was appointed by the U. S. Department of Labor and sent abroad by the Government to study the British labor conditions. This commission was composed of employers of labor and this report is worthy of careful study by manufacturers in this country. That study should be considered with the article on labor conditions in Great Britain which appeared in the April 17 number so that the commission's findings can be read in the light of the differences between the position in Great Britain and in this country.

Perhaps the most important and interesting fact in connection with this commission's report lies in the appointment of such a commitee by the Government as an evidence of the importance of such a study for the benefit of all parties in this country. As far as we have been able to find out, it is the first time in the history of the United States that a commission of employers has been appointed by the Government to study labor conditions in a foreign country, and this method of attempting to arrive at the meat of the situation promises well for future Governmental activities.

We would call special attention to the statement of the commission that the British worker thinks in terms of class rather than individually and tends more toward organization than in this country. The importance of this item in connection with the machinery for the settlement of labor disputes was indicated in AUTOMOTIVE INDUSTRIES of April 17.

It is also worth while to note the definition of capital and labor as found by the commission, which is very different from the customary interpretation in this country. It will be noted that "capital" includes only the stockholder, or the invested capital, and that the term "worker" includes everyone contributing to the actual management, emphasis being placed on the fact that labor includes both brain workers and manual workers.

Altogether the report is worth consideration, particularly as the traditions in Great Britain will be quoted a good deal in this country in the discussions which take place on our conditions.

Fundamentals in Foreign Trade

WHEN one of the speakers at the Foreign Trade Convention last week emphasized that "There is more than profit in foreign trade," he set in vibration a thread of thought that was instantly appreciated, and one that plays a more forceful rôle in foreign trade than is generally acknowledged, namely, that in foreign trade it is just as essential to have regard for the countries you are doing business with as for your own selfish ends.

This sentiment found expression with another speaker recently returned from an investigation through Europe who expressed his deepest thought in the words, "Getting cash against documents at seaport is not the best method of building up foreign trade."

Other speakers expressed this in a variety of ways. It found outlet in one session by the statement that American concerns must be prepared to extend credits much in advance of what they have done in the past and perhaps to a large extent substitute such for the cash-against-document practice followed now. They must be prepared to buy foreign securities, particularly from European allies.

The initial step toward greater extension of credit was expressed in the exhortations of many that officers of our companies and executive heads make extended trips to study new markets. This is essential. Heretofore too many firms have engaged mere hirelings to establish business in Latin-American countries merely because they were familiar with Spanish or had made a trip or so for other lines of industry.

Such is not the fundamental way to establish foreign trade. Such men too often shift from concern to concern and from industry to industry to be of value as representatives in establishing foreign connections. If the head man of the concern will make the investigation, will meet face to face the men he is to do business with, will investigate the standard of business morals, will look into the credit systems of foreign countries, will study the characteristics of the people and will bring back to the Board of Directors a complete picture of the foreign field, then will the reasons for greater extension of credit to such rational limits as 90 or 120 days be better understood and then will it be better appreciated why cash-against-document at seaport is not the surest way to foreign trade success.

There is too wide a gap between the foreign buyer and the American manufacturer. One has not met the other in his home town. One does not clearly enough realize the difficulties of the other. Neither realizes the complete nature of the relationship that exists between them. Neither writes just as good a business letter as he would if they were better acquainted.

The foreign buyer and the American manufacturer are literally oceans apart in their conceptions of service. The foreign buyer has problems that the manufacturer may have heard of but does not comprehend. He does not think intelligently about them. Many makers would never have so persistently insisted on not fitting magnetos to their cars for certain parts of foreign trade if they had known the field.

Many manufacturers would have realized how super-important it is to give more careful attention to crating goods for Latin-American countries than for European countries, solely because those republics are not so uniformly fitted with transportation systems as the old cities of Europe. Frequently, crating that will do for one South American country will not do for another because the transportation systems are fundamentally different. One size of crate is satisfactory on the east coast but may be impossible on the west coast and neither may do for inland points where some of the system of transportation may be by horseback.

Many manufacturers fail to realize that the service question in one part of a South American country can be satisfied in one way, but quite a different policy must be followed in other sections. A case in question is Argentina. The larger cities have service stations and service capacity, but several hundred miles back in the country the thought of service does not exist. The facilities for it are not there. This calls for differences in equipment, as some parts of equipment demand much more service than others.

A better acquaintanceship between manufacturer and foreign merchandiser and foreign consumer is the open sesame to increased foreign trade and more permanent foreign trade. This acquaintanceship must be through the board of directors of the manufacturers. A hireling will not do. The very spirit of manufacture must be instilled into the director who makes the foreign investigation, and he in turn must bring back to his company the spirit of the foreign people, the spirit of their business fabric and a visualization of their complete business structure.

Better Co-operation Urgent Need for Greater Commercial Development

U. S. Chamber of Commerce Meeting Urges Revision of Laws to Fit New Industrial Era—Points Out Necessity of Co-operative Regulatory Control—1100 Attend

By Allen Sinsheimer

ST. LOUIS, April 30.—Special Telegram.—Government, capital and labor must recognize that American industry is entering a new era in its history, and must completely revise laws, organizations and perspectives to accord with the new order.

There must be abolition of the antiquated laws that have failed to keep pace with the higher standards of industry,

There must be legal approval of co-operative industry, of associations of manufacturers or combinations not for price-fixing but for industrial progress, as, for example, with the Webb bill, which should be duplicated for domestic industry.

There must be less Government interference with business and more co-operative regulatory control. Railroads should return to their owners as quickly as Congress can pass legislation providing for Governmental control of rates and regulations.

The American marine must be sold to Americans and be distributed to provide bottoms for every section of the nation.

There must be recognition that a union of labor is as justifiable as a union of capital in the form of a corporation, and labor must be regarded under the new business ethics as a fellow servant with capital and not as a commercial commodity.

Must Develop Foreign Trade

Foreign trade must be developed as a vital factor to the health of our industry, and we should look for our export trade not to the Allies, who need their own raw materials and have not the cash to spare to buy from us, but to South America, the Orient and the European neutral countries. The Allies cannot buy abroad until they can first develop their exports and sell abroad.

These were the major points developed at the convention held here this week by the United States Chamber of Commerce, which was attended by 1100 delegates from every section of the country, and during which papers were read on practically every problem of industry.

That America must prepare to make huge investments abroad to stabilize exchange and trade; that the Government should pay interest on all payments of war contracts that are unduly delayed; that a comprehensive road construction and maintenance policy should be formed at once; that price fixing by the Government should cease in favor of the law of supply and demand; that the Federal Trade Commission should be a purely advisory body and end its prosecutions of industry; that government should be made most economical by a budget and should select its executives and all employees with more regard to their capabilities to assist industry; and that the nation must be educated by all agricultural and industrial bodies to value and understand foreign trade, were among other important recommendations that came from the various discussions.

Good from Anti-Trust Laws

"Nothing is more certain," said Secretary of Commerce William C. Redfield, "than that there has been a great change for the better in the ethics of trade since the anti-trust laws came into being. Business has outgrown the laws intended to control it and in the future will be more co-operative than competitive. A new business standard has commenced, hardly formulated yet, but none the less really operative, whereby industry and commerce recognize three-fold obligations to the public, including the Government, to labor and to business itself.

"Trade associations to deal with common problems working for progress are essential to our business welfare."

The establishment of a Federal Highway Commission, federal appropriations for building and maintaining highways, continuation of the Federal Road Aid Act beyond 1921, and the expenditure of federal funds for highways of a permanent type only, are advocated in the resolutions presented by the highways committee of which F. A. Seiberling is chairman.

The railroads must be returned to their owners, stated Senator A. B. Cummins, but not until legislation providing for a permanent policy of control and regulation has been enacted by Congress. To return the roads now would be to endanger the entire financial structure of the nation. They form 8 per cent of the nation's wealth and if returned now to be operated at existing high costs would be likely to work great harm.

Other addresses were made by Maurice Casenave, head of the French Commission; Joy Joyce Broderick, of the British Embassy, and Lieut. Constantini of the Italian Mission. They told of the financial and other material damage caused by the war and of the need for control of imports until domestic and export trade are established.

There are no discriminations against American products, stated all these speakers, as in favor of products from any other countries, except, possibly, from some colonies, and it is the desire of each of the Allied countries to resume foreign trade with us just as quickly as conditions allow.

Numerous other discussions on all subjects were held, including talks on Housing, Foreign Investment, Payment of War Contracts, Highways, Industrial Training, Industrial Production, Domestic Distribution and Retail Distribution. Numerous resolutions are being considered and will be voted on to-morrow.

S. A. E. Research Committee to Study Fuel

NEW YORK, April 25—A meeting of the Research Committee of the Society of Automotive Engineers was held at Society headquarters in this city yesterday. At the previous meeting, held at the Bureau of Standards in Washington on April 11, it was decided to combine the Committee on Fuel Research and the Committee on Research in General, under the name of the Research Committee.

From the meeting held yesterday, it appears that this Research Committee will concern itself, for the present at least, mainly with fuel problems. A preliminary or sub-committee was appointed, consisting of Samuel A. Miles, chairman; Dr. E. W. Dean of the Bureau of Mines; and Dr. H. C. Dickinson of the Bureau of Standards, with the object of interesting the different industries affected by the fuel problem.

Two Ballot Cars for Indianapolis Leave France

PARIS, May 1—(Special Cable)—Two Ballot cars for the Indianapolis race, accompanied by Wagner and Bablot, are leaving Havre by the *Espagne* on May 3.

W. F. Bradley, special correspondent of AUTOMOTIVE INDUSTRIES, has already cabled that the four Ballot cars left France on April 26. However, from information which has just reached AUTOMOTIVE INDUSTRIES from another source, it would appear that only two cars are actually on the way, the two now advised completing the Ballot team.

Automotive Industries

Industrial Principles In Treaty of Peace

Recommendations of Commission on International Labor Legislation Adopted by Supreme Allied Council

WASHINGTON, April 29—The State Department to-day announced that the nine clauses proposed by the Commission on International Labor Legislation had been adopted by the Supreme Allied Council for insertion in the Treaty of Peace.

The clauses proposed by the commission were somewhat amended, chiefly in phraseology, before being adopted. They now form a part of the Treaty of Peace and are in the nature of recommendations rather than being obligatory upon the nations. The principles thus endorsed by the Supreme Allied Council are the 8-hour day, a weekly day of rest, abolition of child labor, equality of pay for men and women for work of equal value, and "the right of association for all lawful purposes" of workmen and employers.

The text of the clauses incorporated in the Peace Treaty is given below. They were preceded by a preamble in which it is asserted that "the high contracting parties, recognizing that the well being, physical, moral and intellectual, of industrial wage earners is of supreme international importance, have framed a permanent machinery associated with that of the League of Nations to further this great end."

First—The guiding principle that labor should not be regarded merely as a commodity or article of commerce.

Second—The right of association for all lawful purposes by the employed, as well as by the employers.

Third—The payment of the employed of a wage adequate to maintain a reasonable standard of life as this is understood in the time and country.

Fourth—The adoption of an eight-hour day or forty-eight-hour week as the standard to be aimed at where it has not already been obtained.

Fifth—The adoption of a weekly rest of at least twenty-four hours, which should include Sunday whenever practicable.

Sixth—The abolition of child labor and the imposition of such limitations on the labor of young persons as shall permit the continuation of their education and assure their proper physical development.

Seventh—The principle that men and women should receive equal remuneration for work of equal value.

Eighth—The standard set by law in each country with respect to the condition of labor should have due regard to the equitable economic treatment of all workers lawfully resident therein.

Ninth—Each State should make provision for a system of inspection, in which women should take part, in order to insure the enforcement of the laws and regulations for the protection of the employed.

Without claiming that these methods and principles are either complete or final the high contracting parties are of opinion that they are well fitted to guide the policy of the League of Nations, and that if adopted by the industrial communities who are members of the League and safeguarded in practice by an adequate system of such inspection, they will confer lasting benefits upon the wage earners of the world.

The conclusions of the Commission on International Labor Legislation were drawn up in two parts for presentation to the Supreme Allied Council. The first part was a convention providing for the establishment of a permanent World Labor Conference in association with the League of Nations, the second part was made up of a declaration of principles regarding the rights of workers throughout the world which were suggested for inclusion in the Treaty of Peace and, as mentioned above, were so included in somewhat amended form.

To Meet Annually

A meeting of the Labor Conference is to be held annually, and it is recommended that the first meeting be held at Washington next October.

In the permanent organization, the Commission recommended that there be two distinct parts: The International Labor Conference; and the International Labor Office controlled by a governing board.

The International Labor Office will be located at the seat of the League of Nations and will be a part of its administrative organization. The governing body controlling it will comprise 24 members, 12 of whom will be representative of governments, six elected by a conference of employers and six by a similar conference of workers.

Car Imports to France Permitted with 45% Duty

PARIS, April 19—Automobile imports into France, which were prohibited by official decree, April 1, 1917, will be admitted on a 45 per cent duty within a very short time, according to information received from very reliable quarters. This duty is a temporary measure and will remain in force for 18 months only. At the end of this time the custom tariffs will be revised. The 45 per cent figure is only looked upon as a war measure to enable French manufacturers to get into production.

Only a short time ago it was believed that the French would adopt a 45 per cent duty against America and a lower duty in favor of other countries. This idea, which was mooted by the automobile manufacturers and presented at the meeting of the Inter-Allied Automobile Association, has evidently been abandoned as impracticable.

Standard Landing Field Specifications

WASHINGTON, April 30 — Major General Charles T. Menoher, Director of Air Service, has prepared complete specifications for standardized landing fields. It is planned to make these public at the Southeastern Aeronautical Congress which will be held at Macon, Ga., May 2 to 10. The Congress has been arranged through the co-operation of 9 southern states and some 243 commercial organizations covering the South.

Reservations for Summer S. A. E. Meeting

NEW YORK, April 30—Reservations for the Summer Meeting of the Society of Automotive Engineers, which is to be held at the Hotel Ottawa and cottages, Ottawa Beach, Mich., June 23-27, are coming in at a rapid rate. All reservations are to be handled entirely through the S. A. E. office in New York. Accommodations are entirely on the American plan. Following are the rates, for four days of the meeting, namely, June 23, 24, 25 and 26:

Per person (2 or more in one room, without private bath)	$28.00
Per person (2 or more in one room with private bath)	*36.00
Children under five years (in room with parents)	12.00
Children under ten years (in room with parents)	16.00

*This rate applies in case of occupants of rooms containing or immediately adjoining private bath.

Ottawa Beach is about 30 miles from Grand Rapids, Mich., on the east shore of Lake Michigan. It can be reached direct by boat to Holland (from Chicago) on the Pere Marquette Railroad, to Holland, or by Michigan Central, Pere Marquette, Grand Trunk or Grand Rapids and Indiana Railroad to Grand Rapids, and thence by electric through Holland to Macatawa.

The meeting proper will open on Monday evening, June 23, with a business session. This will be preceded by a meeting of the Standards Committee at 10 a. m. Monday.

Provides State Tractor Tests

OMAHA, April 29—Two bills passed by the session of the Nebraska legislature just closed have an important bearing upon trade in passenger cars, trucks and tractors in this state. It is believed that the general effect will be a tendency

to concentrate the trade in the larger cities of the state.

House Bill No. 85 provides that no tractor shall be sold in Nebraska until a sample machine has been tested by three competent engineers of the state university at Lincoln, who shall report to the state railway commission. The commission will compare this report with the specifications and claims of the manufacturer or agent as set forth in advertisements or sales arguments, and shall deny permit for sale if these specifications or claims shall be found false.

The ruling of the commission shall apply only to the particular make of machine under consideration, and not to the whole or other product of a company which manufactures other machines, which do meet specifications and claims.

The commission is also given power to deny sales permits for any tractor on complaint of any two bona fide customers, properly substantiated, that an adequate service station, with full supply of parts, is not maintained within the state. The law becomes effective July 15.

The second bill, Senate File No. 86, declares the sale, trade or disposition of any automobile or tractor void unless the necessary supplies and repairs are carried at some point within the state, being very similar to the first measure. It differs in voiding the sale after consummation as against forbidding sale beforehand. This law is effective July 18.

Tax Not Required on Original Equipment

NEW YORK, April 30—It is not likely that the manufacturer of tires, tubes, parts and accessories will be required to pay a tax on these products under the new War Revenue Bill, when they are supplied to car or truck manufacturers as original equipment. The War Revenue Bureau has not issued any formal rulings as yet, but this is the interpretation placed on the measure by the National Automobile Chamber of Commerce. Manufacturers of such products who supply tires, tubes, parts or accessories to manufacturers of vehicles for paid replacements or repairs, however, will be required to pay a tax.

It is suggested that parts and accessory makers bill the car and truck manufacturers with tires, parts and accessories at the regular price, with a notation on the bill that the 5 per cent War Tax may be added later if the Government so orders. Commissioner Roper has ruled in a letter to a member of the National Automobile Chamber of Commerce that when a part on which a tax has been paid is returned for credit, the amount of the tax may be deducted from the next tax return.

Tone New President of Carborundum

NIAGARA FALLS, April 30—Frank J. Tone has been made president of the Carborundum Co., succeeding the late Frank W. Haskell. George R. Rayner is vice-president, succeeding R. B. Mellon, Pittsburgh. F. H. Manley retains the office of treasurer.

Detroit Union Workers Demand 44-Hr. Week

Formal Demonstration to Claim Wage Increase—Growth of Organized Labor

DETROIT, April 29—On May 1, organized labor in Detroit will wait upon employers with a demand for shorter working hours and increased wages. On the same day a mass meeting will be held at the Arena, where Arturo Giovannitti of New York City, and James H. Fisher of Butte, Montana, both affiliated with the International Workers of the World, will speak. A demand will be made for the release of all workers convicted and imprisoned for labor activities. A number of unions will march from their halls to the scene of the meeting but no general parade will be held.

The general demand will be for a 44-hour week and the adoption of new wage rates, embodying increases from 10 to 25 per cent. Whether there will be a general demonstration is not known. It is said a majority of the unions will participate, and, if that is so, approximately 90,000 workers will be involved. Detroit Federation of Labor officials declare Detroit is now 60 per cent organized, and thousands are joining the movement weekly.

The Typographical Union and the Electrical workers will walk out on that date, it is said, unless demands now before employers are granted. The printers want $42 a week minimum, and a 42-hr. week. The Electrical Workers want a $40 minimum wage and a 40-hr. week. Foundry workers are already on strike in 13 plants. The United Automobile, Aircraft & Vehicle Workers of America called a strike recently at the Wadsworth Mfg. Co., builder of Ford sedan bodies, and approximately 2,000 men are out.

It is said that unless this strike is adjusted quickly, and the rights of the men to a voice in the determination of the conditions of employment upheld, the strike will spread to 25 000 automobile workers. This union, which is now 22,000 strong, is considering calling a general strike. The Wadsworth company is now paying a minimum wage of $6 daily but refuses to recognize the union or deal with the existing shop committee. Several discharged men must be reinstated before the men will return to work. The company is endeavoring to operate with strike-breakers, but is encountering great difficulty, and its production has been greatly curtailed.

The labor movement in Detroit has expanded 100 per cent in the last year. Over 56,000 new members have been taken into the ranks. The United Automobile, Aircraft & Vehicle Workers of America numbered 5,000 one year ago. The membership has now passed the 20,000 mark. Approximately 500 new members are being taken in every week. Machinists, who had one local with 1,500 members last year, now have 4 locals with 10,000 members. Boilermakers were not organized a year ago. They now have 6 locals and several thousand members. The building trades unions have doubled their membership. Twenty-five per cent of the skilled workers were organized a year ago. Now over 60 per cent are organized.

Curtiss Appoints Eleven Commercial Aircraft Distributers

NEW YORK, April 30—The Curtiss Aeroplane & Motor Corp. has entered upon the production of aircraft for commercial purposes and has so far completed its arrangements as to establish 11 distributers in the United States and several in foreign countries. Sales headquarters have been opened at 52 Vanderbilt avenue under the supervision of J. P. Davies, formerly an officer in the U. S. Air Service. Distribution will follow closely the plan of the Willys-Overland Co. with which the Curtiss company is affiliated. Following are the principal distributers and their territories:

American Trans-Oceanic Co., 505 Fifth avenue, New York—Greater New York, Long Island, Westchester County, Rockland County, Fairfield County, Conn.; Hunterdon, Somerset, Middlesex and Monmouth counties, N. J., and the State of Florida. P. L. Freeman is manager.

Curtiss Eastern Airplane Co., 130 South Fifteenth Street, Philadelphia—States of Pennsylvania, Maryland and Delaware, and Cumberland, Salem, Gloucester, Camden, Mercer and Burlington Counties, N. J. G. Sumner Ireland, president and general manager.

Curtiss Southwest Airplane Co., 804 New Wright Bldg., Tulsa, Okla.—State of Oklahoma and northern counties in Texas. B. L. Brookins, general manager.

Curtiss Northwest Airplane Co., 701 Metropolitan Bank Bldg., Minneapolis—States of Minnesota, Montana, South Dakota and North Dakota. W. A. Kidder, general manager.

Curtiss Tri-State Airplane Co., 274 Shelby Street, Memphis—States of Tennessee and Arkansas and northern counties of Mississippi. W. S. Thompson, general manager.

Curtiss Humphreys Airplane Co., First National Bank Bldg., Denver—States of Wyoming, Colorado, Utah and New Mexico. I. B. Humphreys, general manager.

Curtiss Aircraft Co., Atlantic City, N. J.—Cape May, Atlantic and Ocean Counties, N. J.

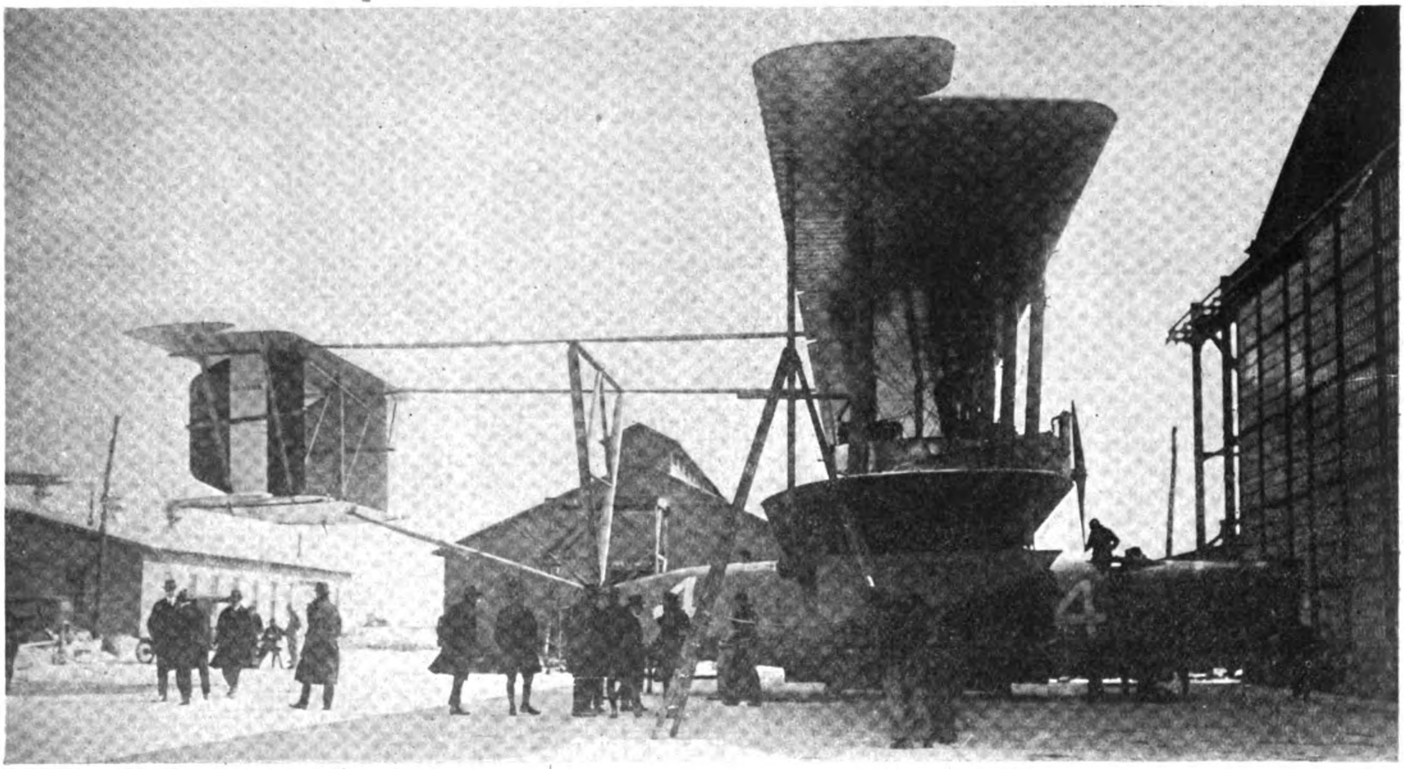
In addition to these, distributers have been appointed for Norway, Sweden, Finland and the Philippine Islands. George W. Browne, manager of the Overland agency in Milwaukee, and the Gibson Co., Overland dealer in Indianapolis, have been appointed local Curtiss dealers. A branch office has been opened in Chicago with George W. Browne as western representative.

The Curtiss company has adapted a number of its planes for commercial uses. Among these are the JN-4D-2 type which was used almost exclusively for training purposes by the American and Canadian governments; the MF flying boat; the HS-2L flying boat; the H-16-A flying boat; the 18-B land machine and a new three passenger plane which has been developed particularly for passenger service and which is styled "Oriole."

It is expected that within a short time a number of used machines of the JN type will be placed on the market at from $2,000 to $5,000. Prices of the other models have been set as follows:

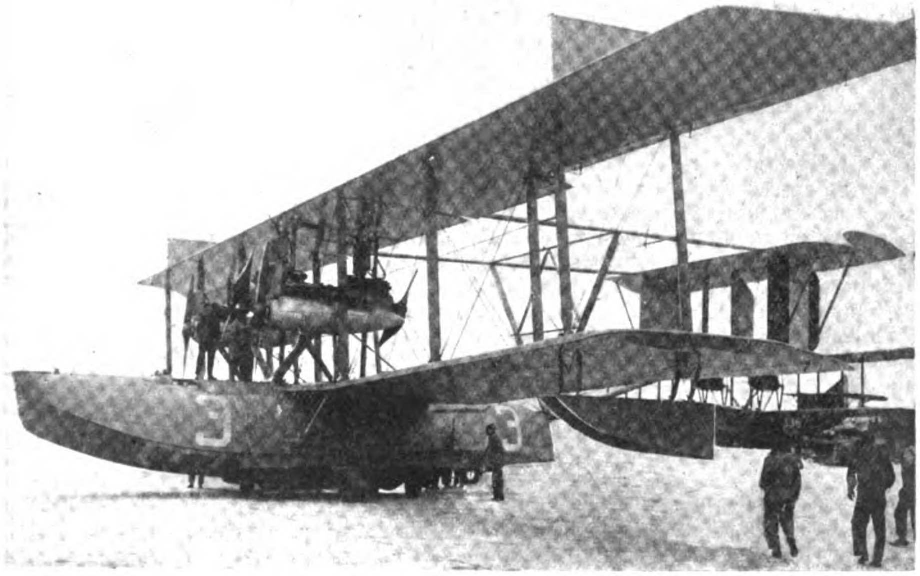
MF, flying boat	$10,000
HS-2L, flying boat	25,000
H-16A, flying boat	40,000
18-B, land plane	25,000
Oriole, land plane	7,500

Putting Final Touches on Navy's Transatlantic Fliers



THREE navy planes will be started at the same time from Newfoundland, probably within a week. They are the NC1, NC3 and NC4. The route will be from Rockaway Beach, L. I., N. Y., to Newfoundland by way of St. Johns, where a stop will be made, and from Newfoundland by way of the Azores, where a stop will be made, to Portugal. The three boats are identical, the principal dimensions being:

Wing spread (upper)	114 ft.
Wing spread (lower)	126 ft.
Wing width	12 ft.
Wing area	2880 sq. ft
Between wings	14 ft.
Overall length	68 ft. 3 in.
Hull length	44 ft. 9 in.
Weight, empty	15,100 lb.
Weight, fully loaded	28,500 lb.
Gasoline capacity (10 tanks)	1890 gal.
Speed	79 knots
Power	4 Libertys



Adopt G. M. Savings Fund Plan

WILMINGTON, DEL., April 29—Stockholders of the General Motors Corp. met here to-day and voted to adopt the Savings and Investment Fund proposed for the benefit of employees. All directors were re-elected.

Briscoe to Design French Car of American Parts

DETROIT, April 29—Benjamin Briscoe, of the Briscoe Motor Corp., Jackson, Mich., has been elected a director of the Bellanger Frères, Paris, France, and will design a moderate priced automobile for the French company along French lines but of American parts to a large extent. He has opened an office in Detroit, and has with him Rodolphe Stahl, an engineer who has been in his companies for nine years.

Briscoe is looking for a small factory to be used as a mechanical laboratory. The Bellanger Frères Co. was one of the smaller automobile companies of Paris before the war, but due to the fact that it was one of the companies selected by the French government for war work, it became one of the largest engineering works in France.

Mr. Briscoe has not severed his connections with the Briscoe Motor Corp., of which he is one of the principal stockholders, a director and a member of the executive committee.

New York Office for Willys

TOLEDO, April 29—Permanent offices of President John N. Willys of the Willys-Overland Co. have been opened at 1710 Vanderbilt-Concourse Building, New York. Mr. Willys expects to remain in New York most of the time directing the affairs of the Overland and allied companies.

Thousands of Unfilled Orders on Books

Demand for All Car Makes Ahead of Supply—Dealers Oversold —Used Car Problem

DETROIT, April 25—There is a tremendous shortage of automobiles in all sections of the country. While the factories are now making nearly as many cars per day as in former years and their production will be normal within 30 days, the unusual demand has swamped them.

The Ford Motor Co., owing to its production facilities and intensive merchandising system, is perhaps the best criterion of conditions everywhere. For the last 4 years this company has had approximately 100,000 unfilled orders on hand at all times. It is now getting into normal production again, and on April 24 it had 69,994 unfilled orders for immediate shipment. These orders are increasing daily in spite of the fact that the company is now running 2600 cars and will be producing 3000 cars daily within the course of the next 10 days.

The condition is almost similar with the Cadillac Motor Car Co., which has approximately 4500 unfilled orders on hand. The company is increasing production as fast as possible, but officials state that it will be several months before they will be able to catch up with the demand. The Cadillac company conducts its own sales and distribution work here. This station, which cares for the Detroit district only, is 100 orders behind and is selling its cars as fast as they are received.

The Paige-Detroit Motor Car Co., running approximately 70 cars a day, is unable to begin to supply the demand. If this company could double production tomorrow it would still take months to catch up.

The Hudson Motor Car Co. proposes to manufacture 20,000 Essex and 20,000 Hudson cars this year. It has 20 dealers who have sold their entire allotment for the year. The company is rushing work on its new Essex plant, and it is probable that both Hudson and Essex production will be materially increased if present conditions continue.

Willys-Overland Co., Toledo, has many distributers who have sold their entire allotment. The company is arranging now to get into production upon its new model, a light four, and it is planned to do this without curtailing in any way the production of its other lines. The company is now running approximately 600 cars a day, while its orders for machines are several thousand cars ahead.

While the Packard Motor Car Co. is just getting into production its dealers in every section are pressing for cars. Work at the plant is being pushed to the limit, but owing to the fact that the company has lost several months, due to the necessity of practically remodeling the entire plant to again handle peace work, its production is bound to fall far below demand. This company makes 15 different body types and the demand is good for all.

The Hupp Motor Car Co.'s production schedule calls for 18,000 cars this year. The demand to date is practically 50 per cent greater than production. Sales officials say 30,000 Hupmobiles could be sold within the next 8 months if the factory was able to produce them. This year's production is 50 per cent greater than that of any previous year. The company has 2500 unfilled orders on its books to-day.

So great is the demand for Dodge cars that the company is now teaching its dealers to turn down orders gracefully without antagonizing the trade. The production system used by Dodge Brothers is rather unusual in that it fixes no set production for the year, aiming to produce just as many cars as possible. The company is now running between 500 and 550 cars daily, yet it is hopelessly behind in orders.

The Reo Motor Car Co., Lansing, has orders ahead for 4000 cars. Owing to the immense amount of work necessary to make the shift from war to peace, this company is not yet in full production. In certain departments a great deal of Government machinery is stored, and it will be some time before entire facilities will be available. The car shortage is very pronounced in every section, sales officials declare. The company is now running approximately 60 cars a day, but owing to its inability to reach capacity production at present, no annual production schedule has been made. The company has 1800 distributers, 90 per cent of whom have sold their quota for months.

The Used Car Problem

The used car is developing an unusual situation. Few people purchased any cars during the war. Fifty per cent of the car purchasers turn in their used cars as part payment for new ones. As a result the used car market is flooded. The demand for cars is so great, however, that buyers are snapping up every desirable machine, whether new or used. While this is the situation at present, it is already apparent that before the end of the year the average dealer is going to have a large stock of used cars on hand, and it is going to be necessary for him to specialize in the merchandising of used cars more than ever.

The factories are already coaching their distributers in used car merchandising methods, advocating new painting, some remodeling and, in many cases, custom-made bodies as a means of promoting sales. With present conditions existing, even cars of obsolete models are being quickly snapped up after being attractively fixed up.

New Ford Factory May Be in Cleveland

CLEVELAND, April 25—This city is petitioning Henry Ford to locate one of his proposed new automobile factories here. Petitions are in circulation, one enthusiastic booster alone securing 1300 names.

New Ford Officials Fill Vacancies

Ryan Succeeds Hawkins—Mayo Probable New Chief Engineer—Other Changes

DETROIT, April 26—New executives have taken hold of the important posts at the Ford Motor Co., to fill the positions of those who have lately resigned. In repairing the holes caused by resignation, the Ford company has taken men from within the organization.

Norval A. Hawkins, who was chief of sales almost from the time the Ford car was made, has been succeeded by William A. Ryan, his former assistant. Two years ago the Ford company abolished its retail sales department, and since that time has been merchandising its cars through a distributers' organization. Mr. Ryan has been in charge of building up this distribution and dealers' organization for several years, while Mr. Hawkins, who supervised the entire department in a general way, devoted most of his time to retail sales.

It was unofficially stated at the Ford plant that William B. Mayo, construction engineer, will succeed C. Harold Wills, former chief engineer, who resigned a few weeks ago. Mr. Mayo is at present directing all engineering work, assisted by M. M. Wibel, who has been connected with the engineering department for several years. Charles Morgana, Jr., who was in direct charge of the engineering department under Mr. Wills, resigned, and is now associated with his former chief in a new automobile project. Mr. Wibel was Mr. Morgana's assistant.

John R. Lee, who was in charge of the social, welfare, profit-sharing and bonus departments, has no successor as yet. C. A. Brownell, advertising manager, has assumed some of Mr. Lee's former duties, it is said. The rest of the work is being handled by his former assistants.

Mr. Wills states that he is going in business for himself. Owing to the personal friendship between Mr. Wills and Mr. Morgana, it is apparent that Mr. Morgana resigned wholly to join Mr. Wills in his new venture.

Trial of Ford Street Car

DETROIT, April 26—Henry Ford's proposed internal combustion engine street car will operate on a track the same as an ordinary street car. It will not be equipped with pneumatic tires but with steel flange wheels, and will have a carrying capacity as great as that of the present trolley.

If Dearborn township officials grant Henry Ford's application for a blanket franchise to operate a line in that township, the internal combustion street car, suggested as Detroit's solution for traction trouble, will be given a practical working demonstration. If the franchise

is granted work on the line will start within 6 months and cars will be in operation within 18 months. Three cars of the proposed internal combustion type are now under construction at the Fordson tractor plant at Dearborn.

Sale of War Vehicles in England

LONDON, April 10—Of the 80,000 trucks under the control of the War Department, 35,000 are American. A number of American trucks are in private use here, though sometimes the drivers are in khaki, presumably awaiting formal demobilization. At a sale at auction this week a number of trucks and motorcycles were disposed of. These were not war-used American vehicles, but a miscellaneous group which the American army had used here exclusively. The disposal of American war trucks from the front does not appear to have been decided on. Meanwhile there are frequent public sales of British war and transport trucks, and apparently there are thousands now lying idle here in various stages of repair. Some American cars, little more than junk, were recently auctioned, and surprisingly good prices were obtained.

The high prices ruling for used vehicles are reflected also in the tractor sales, Fordsons and Titans apparently commanding high prices, in some cases up to 75 per cent of their original cost. This fact merely indicates an unsatisfiable demand because of the closed market. Intrinsically many of these high priced used vehicles are overvalued now as when first sold.

British Truck Discount Rates Decided

LONDON, April 11—There has been much discussion in British trade circles, especially among the dealers, as to the rights of truck buyers to a discount from the manufacturers. With the progress of the trade and the growing demand for service facilities, which the truck manufacturer could not provide on the scale necessary, came the dealers' opportunity to have the discount question reopened. Now it has been agreed that private buyers of British made trucks will be treated as follows:

To the owner or buyer of one vehicle, no discount; two to five vehicles, 2½ per cent; 6 to 10 vehicles, 5 per cent; 11 vehicles and upward, 7½ per cent, agents to give the same terms and to buy at a flat discount of 10 per cent with rebates. A buyer of 50 vehicles will receive the full discount to the exclusion of agent's commission on terms to be arranged by the manufacturer.

Unusual Demand For Labor

SAGINAW, Mich., April 28—The government employment office reports an unprecedented demand for laborers from local plants. Nearly 100 men are placed at work daily and the office is encountering considerable difficulty in finding suitable men. Not even during the war did the employment office experience a greater demand for men than at present.

Sixth Annual Foreign Trade Convention

Government Control of Industry Decried—Allies Need Long Credit—Reciprocal Trade Advocated

CHICAGO, April 25—The Sixth Annual Foreign Trade Convention closed here to-day following a meeting of 1700 delegates, who crowded every session and displayed a keen interest in the development of American foreign trade.

Demand that the U. S. Government should keep its hands off industry, made by Edward Hurley and others, met with the unanimous approval of all. Less Government ownership and interference with industry was practically the keynote of the meeting.

America cannot look forward to a large export business with her Allies and must be prepared to extend long term credit, abolish cash against document at New York, and invest in large amounts in the securities of our Allies. Great Britain, France and Italy cannot allow imports without danger to their existence until they have established their export business.

A reciprocal trade was waged by practically every speaker on the basis that export business cannot be healthy unless there is both purchase and sale, both import and export, and it is good business for the United States to buy its raw materials for conversion into finished products from those countries to which it exports them.

Neither Great Britain, France nor Italy can spare raw materials, and any export business we could do would only serve to further aggravate the present unstable conditions.

The convention was presided over by Alba B. Johnston, president of the Baldwin Locomotive Works, and O. K. Davis, secretary of the association. James E. Farrell, as president of the association, opened the meeting.

Numerous papers were read relating to advertising, foreign exchange, direct selling, shipbuilding and other subjects pertinent to export trade.

A banquet was held, attended by all of the delegates, presided over by John J. Arnold of the First National Bank of Chicago. It was voted to hold the next convention at San Francisco in 1920.

French-American Banking Corp. to Promote Trade Between France and U. S.

NEW YORK, April 29—The French American Banking Corp. has been organized with a capitalization of $2,000,000. Half the stock is held by American interests and the other half by French. It is intended to promote trade between the two countries by facilitating banking advantages in each.

The Comptoir National d'Escompte de Paris holds 50 per cent of the stock, and the First National Bank of Boston and the National Bank of Commerce in New York each holds 25 per cent. The incorporators are: James S. Alexander, president of the National Bank of Commerce in New York; Daniel G. Wing, president of the First National Bank of Boston; Maurice Silvester, American representative of the Comptoir National d'Escompte de Paris, who will be president of the new company, and others. There will be 12 directors, 6 representing the American and 6 the French group.

Highways Transport Committee on Peace Basis

WASHINGTON, April 29—The Highways Transport Committee of the Council of National Defense has been reorganized on a peace basis. It will continue its work of promoting the greater use of the motor truck for merchandise transportation. It consists of the following: Chairman, John S. Cravens of the Council of National Defense; James I. Blakslee, fourth assistant Postmaster General; J. M. Goodell, consulting engineer; James H. Collins, investigator in Market Survey; R. S. MacElwee, second assistant chief, Bureau of Foreign and Domestic Commerce; executive secretary; Charles W. Reid; director of the council, ex-officio, Grosvenor B. Clarkson. It will be assisted by the Highways Transport Committee Advisory Board composed of William Phelps Eno, Washington; Prof. Arthur H. Blanchard, New York; C. A. Musselman, Philadelphia; Raymond Beck, Akron, and John T. Stockton, Chicago.

269,727 Cars in Canada

REGINA, Sask., April 28—In 1914 there were only 67,415 automobiles in all Canada. By the close of 1918 that total had been swollen to 269,727. Ontario has the largest number of cars of any province in Canada, 109,734. Quebec is second in population, but has only 28,338. Saskatchewan in 1918 had 47,239 cars. Saskatchewan with only a third of the population of Quebec has 66 per cent more cars.

Lundane in Charge of Black & Decker New York Office

NEW YORK, April 30—G. R. Lundane has been placed in charge of the office of the Black & Decker Mfg. Co., Baltimore, just opened in the Equitable Building, 120 Broadway, and will supervise its sales for New York City and the state of Connecticut. Mr. Lundane was formerly service manager for Thos. B. Jeffery Co., Kenosha, Wis., and has recently been connected with Findeisen & Kropf Mfg. Co., Chicago.

United Brass & Aluminum Gets Foundry

PORT HURON, April 28—The United Brass & Aluminum Mfg. Co. is erecting a gray iron foundry addition. The proposed foundry will be 72 x 100 ft. and will be ready within 90 days.

Mystery Surrounds Details of Relaxation of British Embargo

Situation Is Complicated by Absence of Definite Details Relative to the Extent to Which American Automotive Manufacturers Can Take Advantage of New Regulations—Efforts Being Made to Obtain Ruling

NEW YORK, April 29—Although details additional to those published in AUTOMOTIVE INDUSTRIES of April 24 concerning the relaxation of automotive import restrictions by the British Government are now available, the position is yet far from clear.

As matters stand at present, manufacturers who were either not in existence or were not exporting in 1913 are precluded from sending their products into the United Kingdom under the terms of the relaxation. Another point which has been raised, but which as yet remains unanswered, concerns the status of British distributers or dealers representing American automotive manufacturers.

It would appear that application for license to import must be made by the British agent of the American maker—not by the latter. It is anticipated that trouble may arise in the case of a dealer who in 1913 was handling a car which is now eligible under the new ruling, but who no longer continues to sell that car. The question has been asked "Has the dealer of 1913 power to make the application for license in view of his 1913 status, does the right to apply for license go with the change of agency. to the 1919 dealer and what is the position of the first-named dealer (the 1913 man) if the car he now handles is not eligible for importation under the relaxed restrictions?"

The National Automobile Chamber of Commerce has cabled England, asking for further information on these points, and it has also asked for a conference with the Department of State officials and with Prof. Kennedy, commercial attache at London, who is now in the United States. At this interview it is proposed to ask for the admission of makes of cars which were not imported into the United Kingdom in 1913, to secure, if possible, an increase in the imports allowed by the British and to obtain a relaxation of the French import restrictions.

In this connection the War Trade Board at Washington has issued the following circular:

"The War Trade Board announce, for the information of exporters in the United States, that they have been informed that the Controller of Import Restrictions of Great Britain has issued notice that British import licenses will be issued admitting into Great Britain automobiles up to 50 per cent of the number (or shipping measurements) of the quantity imported up to September 1, 1913. Each importer must apply for an individual import license and submit a sworn statement as to his imports during 1913.

"Under this ruling the term 'automobile' covers motor vehicles of all kinds, including cycles and accessories.

"In making the above announcement the War Trade Board wish to call attention to the fact that they are not in a position to speak authoritatively on foreign import restrictions, but are merely transmitting the above information for the convenience of those on the War Trade Board's mailing list.. Inquiries with regard to foreign import regulations should be addressed to the Bureau of Foreign and Domestic Commerce, Department of Commerce, Washington, D. C., as that Bureau endeavors to keep informed on the import regulations of foreign governments."

Inasmuch as the U. S. Government records relating to the export of automotive products are compiled on a basis of the fiscal year, which ends June 30, and as the annual volumes dealing with the subject do not give the figures month by month, it is not an easy matter to arrive at totals of our 1913 exports to the United Kingdom covering the period from January 1 to September 1.

A search among the actual monthly records of 1913 has revealed the following data:

Automobiles Imported by the United Kingdom from the United States

1913	Number	Value
January	374	$258,463
February	431	359,799
March	633	462,696
April	373	292,167
May	473	354,686
June	386	289,457
July	300	232,792
August	461	374,098
	3,431	$2,624,158

The following figures, compiled by the Bureau of Foreign and Domestic Commerce, represent our automotive exports to the United Kingdom for the calendar year 1913, as distinct from the fiscal year.

	Number	Value in Pounds Sterling
Complete cars	3,619	744,392
Chassis only	328	71,270
Tires, not imported with vehicles	...	224,428
Other parts	...	500,988
	3,947	1,541,078

Pending the arrival from England of full details concerning the relaxation of import restrictions, together with a definite pronouncement as to the actual conditions imposed, their nature and a definition as to what firms are likely to be affected adversely, either because they were not exporting to the United Kingdom in 1913 or for other reasons, there is but little to be said either in the way of criticism or commendation.

Every effort is being made to obtain official rulings on the various points which are now open to misconstruction and no time will be lost in communicating the results to American automotive products makers.

8,000 Tractors Shipped to Canada in Two Months

OTTAWA, Ont., April 26—According to figures compiled by Dominion authorities, more than 8,000 tractors were shipped into Canada by United States manufacturers during December and January. During the year 1918 21,691 American-built tractors were exported to Canada, 12,805 in 1917 and 3,693 in 1916. There is no import duty on tractors, and it is believed there will be none for the remainder of the year. Canadian tractor makers, however, are insisting on the replacement of the import duty, as but a few hundred tractors were made in Canada during 1918, chiefly because of American competition.

Russian Trade with U. S. Encouraged

NEW YORK, April 29—The commercial department of the representative of the Russian Soviet government in the United States has been organized to encourage American manufacturers in the possibilities of trade with Russia. Circulars containing complete lists of former exports to Russia and present needs are being distributed for this purpose. American agricultural machinery, tractors, plows, harvesting machines, etc., are mentioned as especially suited to Russian needs. Factory, mining and road-building machinery, electrical supplies, cars and trucks are among the American manufactures that would find a ready market in Russia. The organization will make purchases in the United States of materials needed in Russia and will also undertake the sale of Russian materials here.

Surplus Copper Sold

WASHINGTON, April 30—Surplus stocks of copper held by the War Department are to be sold by the United Metals Selling Co., New York City. This material will be sold over a period of time, at current market prices, and will be marketed in such a way as not to affect prevailing price or conditions.

British Council on Imports Appointed

Board of Trade Investigating Imports Restrictions — Demand for Cars Stimulates Action

LONDON, April 29—The president of the Board of Trade, Sir Albert Stanley, has taken the unusual course of investigating the imports restrictions problem by appointing a council, the usual proceedings here in such matters being to refer them to a committee either of members of the Legislature or one solely representative of the business and commercial interests concerned.

The council to deal with these matters has appointed five subcommittees, which will deal with as many groups of commodities. Motor trade interests share with manufactures of wood the task allotted to the third subcommittee.

Machinery and hardware have the fourth subcommittee for their investigations. The Protection on Tariff party's interests appear to be disproportionately looked after as regards the motor imports group; at least two of the members, Edward Manville and Sir Alfred Bird, being well-known protectionists, the former chairman of the Daimler interests and president of the Association of British Motor & Allied Manufacturers, whose chief policy, it seems, is to put a ring around the British trade in the interests of his co-manufacturers. Sir Alfred Bird is a director of the Lanchester company.

However, it may be taken for granted that the importing motor trade interests will make every effort to state their case, which as time goes on is growing stronger in consequence of the increasing call for cars and the swelling chorus of public dissatisfaction with the dog-in-the-manger attitude of the Government in its efforts to please the British manufacturer, who so far seems to have made little effort to begin manufacturing.

One of the defenses made for this procrastination is the state of unrest in the labor world, but it so happens that there are at hand some details of the result of the Ford action in starting the year with a 40-hr. week, whereas the new national standard working week is 47 hr. in most trades and 44 in a very few branches.

The following details are taken from a note in the current number of the *Motor Trader:*

It is, of course, common knowledge that on Jan. 1 a 40-hr. week was inaugurated in the Ford factory, with a minimum wage of 45 cents per hour. A workman with 6 months' service to his credit receives a bonus of 6 cents per hour, so that while "probationers" draw $18.33 per week the minimum weekly pay for the longer service man is $20.83. Some 80 per cent receive more than that.

"When the new scale of pay came into operation and the working hours were reduced from 48 to 40 per week, the two factors combined were found to be equivalent to an increase in wages of 38.8 per cent. At the end of January the increased cost per car for labor was not 38.8 per cent, but 10 per cent, and at the end of February it was only 3 per cent.

"Here we have proof sufficient that it is possible to combine in a British works short hours with an almost undiminished output, and a high wage. Yet if there is one plea more than another now being voiced in the public press, it is that British manufacturers cannot compete because their workers will refuse to speed up production to make up for the shortened working week and higher rates of production costs.

Sir Percival D. Perry, the head of the British Ford interests, in his explanation of the situation notes the effect of the restriction on imports. He said that if the Government in December last had removed the embargo on colonial imports, instead of waiting until early March, it would have been possible to obtain from the Ford factory in Canada certain components which would have increased the output from the Trafford Park, Manchester, works very materially. The difficulty of obtaining them left the English company no alternative but to organize the factory on the basis of a weekly production of 350 cars rather than the 500 which would have been possible.

If the embargo had been removed the price of the Ford car here would have been raised to $1,000 and not to $1,250.

Gray & Davis Has $248,415 Surplus This Year

BOSTON, April 29—In the balance sheet of Gray & Davis, Inc., for the year ended Dec. 31, 1918, the profit and loss deficit of the past two years has entirely disappeared and a surplus of $248,415 appears for the first time. The complete statement issued follows:

ASSETS

	1918	1917
Plant, equipment, etc...	$633,506	$622,691
Investment	....	253,405
Good will, patents, etc..	300,841	308,264
Cash	111,518	77,176
Accounts and notes receivable	285,868	260,198
Inventories	842,178	842,808
Liberty bonds	450,000	....
Ford starter, etc.......	....	86,250
Preferred stock in treasury	10,581	....
Advance payments	....	7,938

Big Tractor Future in Argentina

Must Overcome Competition with Horses and Cheap Labor—Plenty of Education Needed

NEW YORK, April 26—George E. Reed, a partner of Pratt & Co., Buenos Aires, Argentina, which has been connected with the sale of automotive apparatus in Latin America for many years, sailed to-day for Buenos Aires, after spending several weeks in America, arranging for new lines of merchandise, one of which includes the Argentine rights on the Cleveland tractor. Pratt & Co. has Argentine rights on Delco light. A few years ago it handled cars, trucks and accessories, but is now handling only tractors and electric lighting outfits in the automotive field.

Expects Big Tractor Development

Mr. Reed expects a big development in the tractor field in Argentina, which is essentially an agricultural country. He expects the growth to be rather slow, as the heavy traction engine type of farm tractor used in Argentina some years ago made anything but a favorable impression, largely because of the service problem connected with it and the difficulty of securing competent mechanics to keep the machines working. The tractor industry was very materially slowed up because of this.

There are one or two other conditions that will hold tractor sales at a slow pace. Foremost is the price of gasoline, which is selling at $1.50 per gallon, in the central part of the country, although selling at 67 cents per gallon from curbside pumps in Buenos Aires. This fact, placed beside the cheap price of farm labor, indicates what the Argentina dealer has to face. Horses in the central part of Argentina, or "the camp," as it is usually called, are selling from $8 to $9 apiece, and farm help, competent to handle horses, can be had at $13 a month. Food for the horses is practically negligible in that they are generally on pasture all the time. It is expected that a competent person to operate a tractor will have to be paid $30 a month or more.

But the greatest tractor problem is going to be that of service. Some of the farmers are hundreds of miles from railroad stations, and in general the farmers in the farming vicinity around Buenos Aires and Rosario are much farther from the small town than in America. In Argentina the capacity of the small town dealer to give service cannot be compared with that of America, so that it is going to be a man's job to put a tractor across in Argentina, which will undoubtedly be one of the greatest tractor markets outside of the United States and Canada.

Full Instructions Needed

Mr. Reed thinks that what is needed most in the merchandising of tractors in Argentina are very complete descriptive catalogs, instruction books, maintenance

charts and price lists in Spanish. For the Argentina farmer these books will have to be much more elementary than the corresponding books in America. The field of the tractor has been established in the United States and development started. In Argentina it has yet to be established.

The average farm in Argentina is many times as large as the American farm. In fact, there are many farms that contain 9 square miles, or 5760 acres. Such farms offer good opportunities for the tractor. It is not certain just what type of tractor will be most suitable for the Argentina field, and this can be determined only after considerable experience.

Mr. Reed says that Argentina is short of cars, owing to the fact that the port of Buenos Aires has been practically closed since early in January, due to political and social conditions. Business is very slow throughout the agricultural or camp area, as there are no buyers for wheat, meat and wool, the products of the farms, and in consequence the farmers are not purchasing as they normally would. In spite of this, the majority of the salesrooms in Buenos Aires are practically empty of automobiles.

Some months ago there was what literally amounted to a tire "war" in Argentina, due to most of the dealers being overstocked, which started price cutting. Argentina is very heavily stocked with tires to-day, and the present year will, in all probability, not be a profitable one for tire trade.

—

Decrease in Army Expenditures

WASHINGTON, April 28—The Aircraft Production division decreased its expenditures in March, 1919, by 38 per cent as compared with the average previous month's withdrawals from the treasury. Military aeronautics decreased 52 per cent. Military aeronautics expended $2,518,000 and aircraft production $11,082,000 in March, 1919. Average monthly withdrawals for previous months were $18,000,000 for aircraft production and $5,230,000 for military aeronautics, these averages being for the months of July 1, 1918, to Jan. 31, 1919. Total expenditures for the army in March, 1919, were $494,241,000 as compared with an average monthly expenditure of $850,866,000 for the preceding seven months.

—

Reconstruction Information Offered to Industry

WASHINGTON, April 28—The Reconstruction Research Division of the National Defense Council is now ready to give the business world whatever information relative to reconstruction it has been able to compile. The division has charge of all the federal official bodies and has access to information relative to foreign reconstruction activities and also data relative to domestic business, which has been gathered during the war by the various war administration boards. Manufacturers who are desirous of securing any of this information can do so by applying to the committee.

Completing Delivery of War Orders

Over 90% of Some Equipment Turned Over—Small Amount Not Finished

WASHINGTON, April 26—Delivery of airplanes, compasses, propellers, cameras, balloons and machine guns ordered by the War Department averages over 90 per cent of the orders placed. Delivery of motor trucks, aviation fabrics, bombs and engines, etc., averages between 51 and 90 per cent of the orders placed, and deliveries of balloon fabrics, Hispano-Suiza 300 hp. engines, etc., average less than 51 per cent of the orders placed. Of the 4846 DeHaviland-4 planes which were ordered 4842 have been delivered, and of the 62,075 machine guns ordered 57,660 have been delivered. Seventy-seven motor truck units' outfits were ordered, of which 69 have been delivered. Following are the statistics showing the status of the Air Service orders on March 23, 1919:

	Orders	Deliveries	Per Cent
Deliveries of Over 90 Per Cent			
De Haviland-4 planes....	4,846	4,842	99.9
Compasses	12,650	12,644	99.9
Cameras, gunnery training	1,609	1,599	99.3
Oak lumber (1000 ft.)....	311	308	99.0
Balloons, kite type "R"..	910	898	98.6
Spare (train) propellers..	33,631	33,064	98.3
Gun yokes	20,607	20,007	97.1
Oxygen apparatus	6,100	5,609	92.0
Lewis machine guns......	43,950	40,294	91.7
Vickers machine guns....	18,125	16,366	90.3
Deliveries of 51 Per Cent to 90 Per Cent			
Motor truck outfits......	77	69	89.6
Airplane fabrics (1000 yd.)	11,568	10,263	88.7
Hispano 180 hp. engines..	6,000	5,075	84.5

Hanch Acquainted with French Problems

PARIS, April 15—C. C. Hanch, who has been representing the National Automobile Chamber of Commerce at the Inter-Allied Conference of Automobile Manufacturers, left Paris to-day for London. It is the intention of Mr. Hanch to sail for America from Liverpool on May 3. During his stay in France Mr. Hanch was in close touch with the leading automobile manufacturers.

Among the subjects which have been discussed are standardization, regarding which the French are now particularly interested: the diminution of taxes on automobiles; the dates of the national shows and the treatment to be accorded to foreign exhibitors.

The value of standardization is fully appreciated by the French manufacturers and a wonderful opportunity now presents itself for working hand in hand with the Society of Automotive Engineers. There is a danger that the French makers will tackle standardization purely from their own standpoint and thus set up standards which will have nothing in common with those in force in America and England.

—

French Government to Go Into Production

PARIS, April 16—A project is afoot to make use of a portion of a new state arsenal at Roanne for automobile and aviation production. In the technical report which has just been issued it is stated that the shops erected for the production of 75 mm. shells are particularly suited for aviation engine and automobile parts in big series. These shops are particularly well provided with Gridley automatics.

The "Verdun" building and 155 mm shell shops are suitable for agricultural implements and tractors. For these latter it is proposed to make use of trucks and tractors returned from the front. The "Marne" buildings are designated as suitable for aviation and automobile spare parts. The presses in these buildings are capable of handling all the stampings necessary for agricultural implements and tractors.

Car manufacturers are protesting against the state coming into direct competition with their industry by this proposed transformation of the Roanne arsenal.

—

Tractor Imports to France to Stop July 1

PARIS, April 16—Agricultural tractor imports into France will be prohibited on July 1, if French makers are in a position to meet national requirements, is the official statement made by Minister of Ravitaillement Boret.

At the present time not only are tractor imports permitted, but the Government is buying American machines and selling them to groups of French farmers. In addition to this, as has already been said, the Ministry of Agriculture is offering a subsidy equal to half the cost of the machine to purchasers of tractors who give the necessary guarantees that the tractors will be kept at work.

It is doubtful if the French makers will be in a position to meet requirements by the date indicated. The biggest producers at the present time are Renault, De Dion-Bouton, and Latil, but others who are rapidly getting into production are Peugeot, Schneider, Paris General Omnibus Co., Delahaye and Gnome & Rhône.

Want Discriminatory Tariff Against American Cars

Inter-Allied Congress Indicates Desire of European Manufacturers for Protection Against American Automotive Products— Government Support Doubtful

PARIS, April 10—The discriminating attitude of European automobile makers against America in the recent inter-allied automobile conference here, when a 10 per cent duty among European Allies and a 45 per cent duty against America was discussed, shows the attitude of the European maker toward America. No vote was taken in the Congress, and had there been, the European representatives could have out-voted America 13 to 1.

The English makers are reported to be the prime movers in this discriminatory tariff against America. France is hesitating on the question and Italy is indifferent because of the progress she made in automobile and truck production during the war. This lack of uniformity of views and broadly diversified interests are in themselves sufficient reason why a discriminatory policy against America cannot hope to find favor in the eyes of European governments. The British public is already well nigh disgusted with the exorbitantly high prices the British makers are asking for their automobiles and also the slowness with which they are getting back into their manufacturing stride.

Hanch Visits Italian Factories

Charles C. Hanch, American delegate to the congress, returned to Paris this week after a trip through Italy, where he visited the automobile factories in Turin and Milan. It is his intention to remain in Paris for a couple of weeks, during which time he will be in touch with the French automobile manufacturers and American officials now in France. At the end of this time he will go to England for two weeks before sailing for home.

The presence of Mr. Hanch in Europe has given an opportunity to the automobile manufacturers to discuss completely the somewhat difficult question of import duties as they affect them individually. A certain amount of misapprehension appears to exist as to what really took place at the inter-allied conference attended by accredited delegates from France, England, Italy, Belgium and the United States. This can be attributed to a rather unfortunate attempt on the part of the French officials to maintain undue secrecy; the inevitable consequence was that an effort was made to pierce the veil.

European Makers Want Protection

Throughout Europe there is a feeling, varying in intensity, that the automobile industry ought to be protected against foreign competition for a certain period. In a small degree the European manufacturers want protection against one another, but they all want protection, for a period varying from a few months to a few years, against America. English manufacturers are the most resolute partisans of a system of protection against America. It is believed that the English delegates at the automobile conference were responsible for the suggestion that there should be reciprocal duties among the Allies, on a basis of 10 or 15 per cent, but that in no case should the duty be lower than that in force before the war. The practical outcome of this would be that France, England, Italy and Belgium could work together on a moderate basis of 10 to 15 per cent duty, while against America there would be a 30 or 45 per cent duty, with the impossibility of America dropping her duty in order to put herself on an equality with the Europeans. In other words, there would be a minimum tariff among European nations and a maximum tariff in all these countries against America.

This suggestion is only important as a revelation of the working of the minds of European automobile manufacturers. It appears therefore that on this question the congress limited itself to a complete exchange of views, when Mr. Hanch took the opportunity of advising the European makers on American opinion and conditions.

It is but a natural outcome of the events of the last 5 years that the European automobile industry should now be in a state of unpreparedness and dissatisfaction. While in America the whole of the automobile industry was controlled and transformed from peace to war conditions, according to a uniform plan, in Europe the conditions varied according to the countries and also according to the factories in those countries.

French Production Ceased During War

In France the whole of the factories were shut down at the beginning of August, 1914, by the law calling every man to the colors. Trained engineers and unskilled laborers went into the army on the same footing and often with the same rank. It was not long before the folly of this plan revealed itself and engineers and skilled workers were called back and returned to the factories to make shells or other war equipment ordered by the Government. There could be no question of building automobiles for private use, for the right to travel by automobile practically ceased with the outbreak of the war. While the automobile factories were making shells, trucks for the French army were being bought in America. As the war progressed the automobile factories gradually changed over from shells to aviation engines, tanks, trucks, tractors, staff cars and other similar material for which they were more suitably equipped. The outcome was that when the armistice was signed a few French automobile factories were making shells, many were building aviation engines, some were on tanks and a small number on more or less purely automobile work.

In England conditions were different. Military service being voluntary in 1914, automobile manufacturers tried to avoid accepting war contracts, their idea being, evidently, that the war could not possibly last more than a few months, and at the end the advantage would lie with the man who had kept his organization together. The Government had to force the automobile manufacturers into war work, this work consisting at first in the production of shells. Later the development was similar to that of France, the factories being big producers of aviation engines, while trucks were being purchased in large quantities in America.

Italy's Truck Program

Italy had an entirely different experience. Coming in later, the Italian Government had time to profit by the mistakes of France and England, for instead of converting their automobile factories into munition works and going to America for trucks, they intensified the production of their automobile factories on automobile work, and were able to meet not only all their own army automobile requirements, but to supply immense quantities to France and also important numbers of vehicles to England and even to the American army.

Finally, the Belgian industry was picked clean by Germany. Of the three leading European nations Italy enjoys the most favorable position, thanks to the original foresight of her Government. In both France and England there are some factories which have changed their organization so little that at the present moment they are capable of producing more automobiles than immediately before the war. On the other hand, there are establishments which have not built an automobile for 4 years and cannot get back into production in less than a year.

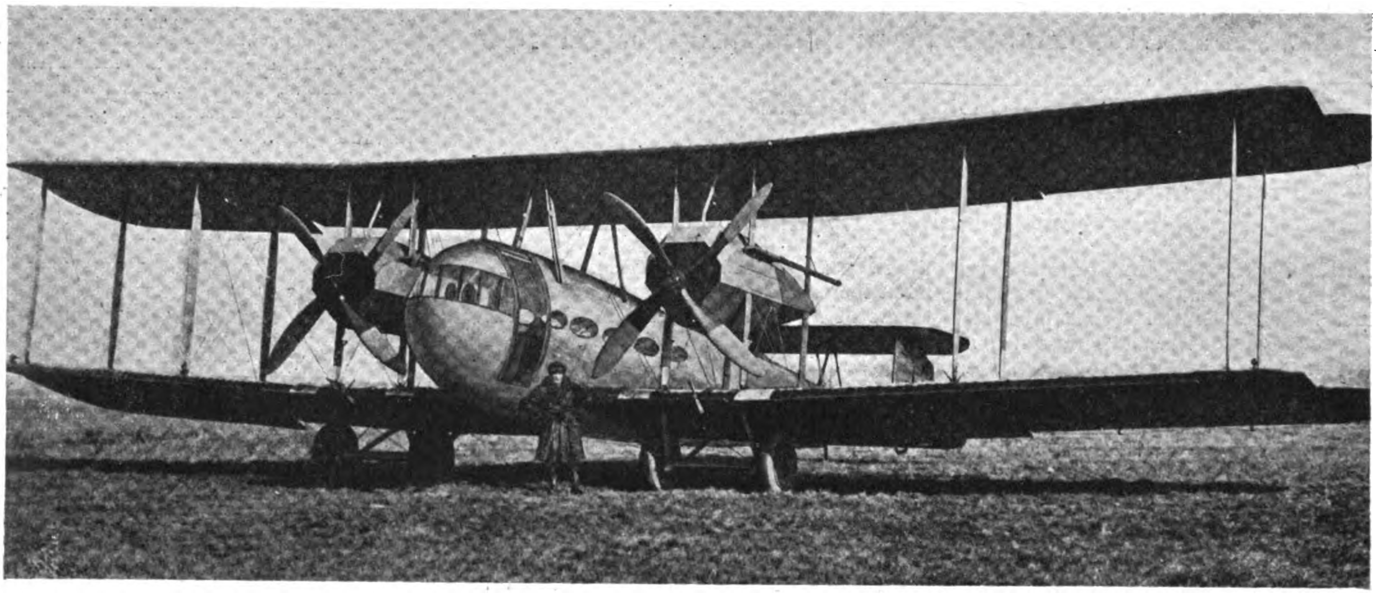
The European markets are not equally favorable to American imports. American automobiles always have been and always will be difficult to sell in Italy, while during the war Italy has become an important automobile exporting nation. From the American viewpoint France is a better field, but still a very difficult one to do business in. Finally England always has accepted American automobiles readily and is prepared again to purchase them in quantities.

Dividends Declared

Pennsylvania Rubber Co., Jeannette, Pa., eleventh quarterly dividend, 1¾ per cent on preferred, payable June 30 to stockholders of record June 15.

Borg & Beck Offices Moved to Chicago

CHICAGO, April 29—The Borg & Beck Co., which recently opened a factory here, has moved its offices from Moline to 914 S. Michigan avenue. The plant at Moline will be continued.



Vickers airplane with large twin engines

New British Airship

WASHINGTON, April 25—Vickers, Ltd., of London has announced the approaching completion of the R-80, a new rigid airship, which it is believed will fly the Atlantic with ease. It is expected that the machine will be ready for trials in May. It has been designed entirely by Vickers. The ship has bow-mooring attachments that will permit it to be moored out from a tower in such a manner that it can turn in any direction and lie with the wind. Four cars are attached to the hull—a forward control car and machinery car, and two wing cars for machinery fitted on opposite sides of the ship. There are 4 Wolseley-Maybach engines of 240 nominal brake horsepower each. The airship will carry a crew of 16 and will have accommodation for a good number of passengers.

British Car on Co-operative Basis

LONDON, April 10—With the purchase of the Bell Motor Co., Ravensthorpe in Yorkshire, by the Co-operative Wholesale Society, the production of a popular priced car on a co-operative basis will be inaugurated. The C. W. S. has been in existence since 1864, organized to buy goods wholesale and sell it to societies forming its membership. Production is expected to begin at once. No details of organization or production have been disclosed.

Co-operative Production to Compete with American Car

LONDON, April 10—British motor manufacturers who have decided to pool their interests in a standard product for the largest range of mass production, and the similar step taken among the French trade, is largely intended to help realize the advent of a successful competition in price and quality with the American car in the colonial market. The Buick six, for instance, can be landed in Australia from the United States for $2250, whereas the British Rover and Arrol Johnston cars, now listed at $3,500 even in Great Britain, bring at least $500 more in Australia. Competition at such rate is out of the question. The colonies are independent of the mother country in their domestic affairs, and it is all too probable that while our manufacturers are holding back restarting the industry and blaming the workers and everybody else but their own lack of confidence, courage, energy and prevision, the American trade will reap the harvest of cars in territories peculiarly British, and having a preferential tariff for British goods.

New Muffle Forms for Heat-Treating

LONDON, April 1—War-time products demand advanced and varied forms of muffle for heat-treating pieces several feet long. Some of the muffles thus called for were quite small and were adapted for heating electrically, but for the most part gas was used for the larger sizes. One type of muffle evolved is vertical, after the fashion of a retort in which the article to be treated is suspended.

The exclusion of air is so complete and the gases so well directed from contact with the pieces being treated, that they invariably emerge without the scale and soft-spots incidental to scaly pieces. Crank and cam shafts and axles are being annealed and otherwise restored after crystallization through protracted use.

The virtues of this new type muffle appear to be due to a combination of perfect sealing of the retort-like chamber, the presence of an inert gas, and suspension of the piece (or pieces) as opposed to the alternative practice of resting the piece (or pieces) in contact with the muffle floor as in the horizontal muffle.

These vertical muffles or retorts were much used in the war for treating airplane-struts and landing chassis and their possible value is being inquired into by cycle and motor makers, because of the seeming greater freedom from distortion of parts thus treated.

Standardization Work in England Undergoing Changes

LONDON, April 3—The standardization work of the Institution of Automobile Engineers has been undergoing several changes, and because of this has slowed up a good deal. This work has been carried on by a joint technical committee representing the interests of the motor industry and also the engineers. The technical committee of the Society of Motor Manufacturers & Traders has turned its functions over to a technical committee to be formed by the Association of British Motor & Allied Manufacturers, which means that a complete division of all the committees and sub-committees working on automobile standardization will have to be made, and the complete work will correspondingly be retarded for some time.

Because of this all engineering matters related to the automobile industry will be referred to the technical committee of the Association of British Motor & Allied Manufacturers. This committee will form the only means of communication between the automobile industry and the British Engineering Standards Association, which is the one organization in Britain that approves of standards. Once a standard is issued by this association it is immediately accepted by the manufacturers of the country.

More Room for Union Truck Co.

BAY CITY, Mich., April 28—The Union Motor Truck Co. has increased its capital stock to $500,000 and a new factory will be built at once. The company was organized 3 years ago. A small company began experimental work, putting the first Union truck on the market a few months later. Manufacture on a small scale continued, but because of the war the company found great difficulty in getting material. This difficulty has been removed and during the last few months it has received more orders than it can turn out with its present facilities.

Harper Sons & Bean Enter Car Field

LONDON, April 10—The firm of Harper Sons & Bean, Ltd., established in 1826 and employing some 10,000 persons in 3 plants in the Birmingham-Wolverhampton area, and whose output was principally stampings, forgings and castings, recently acquired the patterns, jigs and other manufacturing rights in the Perry light-car. There is also intended to be listed early next year a special new model styled the Bean car, designed for mass production. Meanwhile up to about 2000 of the Perry light-car, suitably improved, will be put through for the season 1919-20.

The company's shops are 600 ft. long and the foundry has an output of 1000 tons of castings a week. The company for many years has supplied a vast quantity of stampings to the motor trade and also, to a smaller extent, numbers of completed components, such as front-axle assemblies, etc. It is rumored that the mass production car will be listed at $1000 and will be specially suited for the colonial trade.

Copeman Laboratories Reorganized

FLINT, MICH., April 25—The Copeman Laboratories, Inc., has been purchased by New York and Detroit banking interests and the business will be continued by the new stockholders under new management.

Lewis Searing of New York, formerly vice-president and general manager of the Denver Engineering Co., Denver, Col., has been elected president and general manager and has already assumed active control of the business. L. G. Copeman, formerly president, has been elected to the board of directors. Production will start at once.

Detroit Culto-Tractor Locates

DETROIT, April 26—The Detroit Culto-Tractor Co., a new company incorporated at $1,500,000 for the manufacture of a farm tractor to sell at $755, has leased the Indian Village garage on Jefferson Avenue, and is converting it into a manufacturing plant. The company plans to be in production by May 1, turning out 25 machines daily. It claims orders for 3700 machines. The company will confine its efforts to assembly at first, some machining and finishing work.

The officers of the company are: President, J. J. Rowe; vice-president, H. M. Jerome; second vice-president, H. B. Kramer; secretary and treasurer, P. H. Kramer. S. M. Duffield is sales manager and S. R. Du Brie chief engineer. Mr. Jerome will be production manager.

The tractor is a three-wheel device with a single drive wheel, and was briefly described in the March 20 issue.

Goodrich Additions Total $93,000

AKRON, April 25—The Goodrich Tire & Rubber Co. has taken out permits for the construction of fireproof brick buildings to total $93,000. A machine shop, costing $49,000; an addition to a substation on Falor Street to cost $15,000, and two additions to present buildings costing $29,000 will be built at once.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Austin Touring Car Sells for $2,475

BIRMINGHAM, ENGLAND, April 9—The prices of the Austin 20, one of England's post-war models, anticipated as one of the production jobs of the country, have been determined. The chassis list at $1,975, the touring car at $2,475, the coupe at $2,975 and landaulet at $3,125.

Durant Denies Ford Purchase

DETROIT, April 26—W. C. Durant, president of General Motors Corp., emphatically denies that the corporation is to buy out Henry Ford's interest in the Ford Motor Co, as reported in some of the daily papers.

"There is absolutely no truth in the report that the General Motors Corp. has acquired or is negotiating for possession of Henry Ford's holdings in the Ford Motor Co.

"You may deny the report emanating from New York to this effect just as strongly as you wish and sign my name to it."

Republic to Build in Canada

LONDON, ONT., April 26—The Republic Motor Truck Co. will put up a factory here as its Canadian headquarters. A site has already been chosen and the erection of the new plant will commence immediately. During the course of construction an old munition plant will be occupied.

National Body Mfg. Co. Newly Organized

NASHVILLE, TENN., April 25—National Body & Mfg. Co. has been completely reorganized as the National Body Mfg. Co., with a capitalization of $50,-000, and will immediately start production of five-passenger bodies. H. O. Blackwood, owner of the H. O. Blackwood Tire Co., Nashville, Tenn., is president of the concern, the other officers being Charles R. Wood, Nashville automobile dealer, and Pollard Caldwell, the president of the Sterling Candy Co., vice-presidents, and J. N. Moorehead, secretary-treasurer.

S K F Industries a Holding, Sales and Engineering Company

Editor AUTOMOTIVE INDUSTRIES:

Through an unfortunate slip in our copy department a recent news item was sent you announcing in error that the reorganization of our interests, effective May 1, would be a physical consolidation of the underlying companies. The new company, S K F Industries, Inc., will be simply a holding, sales and engineering organization.—S K F Industries, Inc.

1,000,000 Fords Planned for One Year

DETROIT, April 29—The Ford company is now about to hit its full production stride. From 1300 cars daily this company has run production up until an average of 2600 cars were turned out each day this week. According to production officials, May will see production boosted to the 3000-car mark, and every effort is now being made to increase this to 4000 daily to meet the unusual demand.

In November the Ford company was operating on practically 100 per cent war basis. Ford did not wait for the cancellation of his contracts, but suspended all war operations the day after the armistice was signed. As a result he began to get back into peace production several weeks before any other automotive company in this district. This foresight enabled him to be operating on a 50 per cent basis by the first of the year, and he will hit his full production stride long before the other companies have fully recovered. On April 24 the Ford company had on hand 59,994 unfilled orders, and this total is increasing every day. From Aug. 1, 1919, to Aug. 1, 1920, the Ford company plans to manufacture 1,000,000 cars.

Splitdorf Closed for Inventory

NEWARK, N. J., April 25—The Splitdorf Electrical Co. has finished all Government work at its main plant, and has closed down temporarily for inventory. Manufacturing activities will be suspended until May 5, when the Government inventory is complete.

Chevrolet Turning Out 700 Cars Daily

DETROIT, April 24—The Chevrolet Motor Car Co. is manufacturing on a set schedule of 700 cars daily. Sales officials declare the demand far exceeds production.

Schwartz Electric Back to Horns and Other Supplies

ADRIAN, MICH., April 26—The Schwartz Electric Co., which, during the war produced munitions, has returned to peace activities: manufacture of automobile horns and other motor supplies. The company has orders now to supply 32 car manufacturers. At present some departments are working 13 hours daily. If sufficient labor could be obtained, night shifts would be put on. The company is making 1800 small horns a day, 800 large ones, 1000 circuit breakers, and 1200 push buttons. Cord assemblies are also being manufactured.

Service Products Corp. Will Make Radiator Fans

INDIANAPOLIS, April 26—The Service Products Corp. has recently been organized with $50,000 capital to manufacture radiator fans for cars, trucks and tractors, with the following officers: President, Harry J. Enders; secretary and treasurer, R. B. Parrott, and chief engineer, R. C. Root. Annular bearing fans will also be featured.

Men of the Industry

Changes in Personnel and Position

Cole Foreign Representative Abroad

INDIANAPOLIS, April 28—Pablo Homs, export manager of the Cole Motor Car Co., will leave early in May for a trip to important foreign commercial centers to establish export facilities for the company. He has secured distribution for the Cole in Europe, South America, Australia, Mexico, Cuba and the West Indies, subject to the removal of restrictions on private trade. It is estimated that between 10 and 20 per cent of the Cole output will be exported in 1919.

Major T. P. Searight, director of H. M. Hobson, Ltd., London, makers of the Claudel-Hobson carbureter, is now in this country on a business visit.

Capt. W. J. Pearmain, late instructor of artillery, First Army, A. E. F., has returned from France and has been appointed experimental engineer with the Wallis Tractor Co., Racine. Before going overseas Captain Pearmain was in charge of the experimental department of the Mitchell Motors Co.

J. F. Richman, former superintendent and factory manager of the Cole Motor Car Co., Indianapolis, is now manufacturing manager of the Allen Motor Car Co., Fostoria, O.

Arthur Kirkland, formerly with the Bureau of Aircraft Production, has been appointed sales engineer of the Detroit Tool Co.

J. S. Holihan, former sales manager of the Standard Motor Truck Co., Detroit, has joined the sales force of the Garford Motor Truck Co., Lima, O.

J. Berge, formerly of the Stewart Warner Speedometer Corp., has been appointed chief engineer of the speedometer department of the Champion Ignition Co., Flint.

R. B. Huffard of the truck department of the International Harvester Co., Chicago, has been engaged by the Handy Motor Truck Co., Detroit, as consulting expert.

Sid J. Black is vice-president in charge of sales of the Cleveland Automobile Co., which is erecting a factory for the manufacture of the new Cleveland car.

William M. Farans has been appointed special representative for the State of New York for L. Sonneborn Sons, Inc., oil refiners. He has just been released from duty as chief petty officer in the Navy.

R. E. Manly, of the Manly Sales Co. at 6253 Ellis Avenue, will have charge of the Chicago office just established by the Fulflo Pump Co., Blanchester, O.

John F. Neville is now with the Hilo Varnish Corp., Brooklyn. He was formerly with W. A. Tottle & Co., Inc., Baltimore, and Jas. A. McCafferty & Sons, Brooklyn.

DeLisser Made Ajax President

NEW YORK, April 30—Horace DeLisser has been made president of the Ajax Rubber Co., succeeding H. L. McLaren, who resigned recently. C. R. Collins, advertising manager, severed his connection with the company a few weeks ago. His successor has not yet been appointed.

Hunt New Sales Manager for Disteel Wheels

DETROIT, April 30—George H. Hunt has been appointed sales manager of the wheel division of the Detroit Pressed Steel Co. For several years Mr. Hunt was manager of the branch here of the Stromberg Carbureter Co. and for the past year was local representative of the Edward G. Budd Mfg. Co., Philadelphia, and the Budd Wheel Corp.

Steward Slosson has been appointed Pacific Coast manager of the Rubber Products Co. He was for several years Coast representative for Firestone motorcycle tires. The Rubber Products Co. is increasing its manufacturing and storage space at its Barberton, O., factories. Additional office space is also planned.

F. H. Prescott has been appointed designing engineer on motor and generator equipment for the Remy Electric Co. Before going into Government service as second lieutenant in the Engineering Reserve Corps, he was a designing engineer in the automobile equipment section of the Westinghouse Electric & Mfg. Co.

Martin K. Whalen has joined the force of the International India Rubber Co., South Bend, as its southern representative. He has been acting as special representative for the Century Plainfield Tire Co.

Paul LaCroix, general manager of the Rubay Co. plant, Cleveland, has been elected vice-president of the company.

R. A. Fisher, for 18 months with the flying corps, has joined the sales and engineering force of the J. R. Stone Tool & Supply Co., Detroit. Before entering the service he was connected with the Curtiss Aeroplane & Motor Corp. and the Continental Motors Corp.

W. D. Bell, Detroit, who recently resigned from the Parker Rust Proof Co., is now connected with the Wilson Foundry Co., Pontiac, where he has charge of the board contract department.

Stephen T. Gorman has taken charge of the office of the Ladish Drop Forge Co., recently established at Detroit.

Lee to Manage Saxon Factory

DETROIT, April 28—Harry S. Lee, during the war superintendent of the Wright-Martin Corp., Long Island City, has been made factory manager of the Saxon Motor Car Corp., Detroit. Before entering government service he was manager of the Aluminum Castings Co.

H. G. Semmons, prior to the war with the Studebaker Corp., has joined the Chevrolet Motor Car Co., Flint, as assistant sales manager.

Ernest L. Kreamer, advertising manager of the Oakland Motor Car Co., Pontiac, before resigning to enlist in the army, is now a member of the Howe, Fordham & Kreamer Co., Chicago, a new law firm.

A. G. Drefs, just out of government service, has opened offices in the Book Building, Detroit, under the name of Drefs, Cunningham & Drefs. The company will act as consultants for automotive industries on problems of organization, production, distribution, finances, accounting and general taxes.

C. V. Durham, with the Buick Motor Car Co., Flint, for many years, has been promoted from general superintendent to works manager of the plants.

H. E. Westerdale, sales manager of Heath-Duplex department of McCord Mfg. Co., with Ward Keller, eastern sales manager, has resigned to form the Lexington-Ohio Co., Cleveland, to handle Lexington cars.

J. C. Given, southern district manager of the L. A. Young Industries, Inc., Detroit and Shelbyville, Ind., has been appointed sales manager of the power division.

Andrew V. Terek, recently released from the Naval aviation service, has returned to the Bantam Ball Bearing Co., Bantam, Conn., as master mechanic in charge of the upkeep of the factory.

Frederick Robinson, who for many years was vice-president and general manager of the J. I. Case Threshing Machine Co., Racine, died April 23 at the age of 57. He had been ill several years, for this reason retiring in 1915, but remaining a director of the Case company.

James Viles, chairman of the board of directors of the Buda Co., Harvey, Ill., and father of L. M. Viles, president of that company, died in Chicago, Sunday, of a complication of diseases at the age of 64. He became president of the Buda Co. in 1907.

Gasoline Legislation Defeated

SAN FRANCISCO, April 26—As a result of opposition of the trade associations and the Chamber of Mines and Oil in California, Senate Bill No. 711, which proposed to establish gasoline specifications has been defeated. It was brought

out in opposition to such legislation that the price of gasoline and its quality are matters of supply and demand, and that legislative tinkering will only result in complicating a situation which calls for the gravest scientific study.

According to late quotations, gasoline is now sold at service stations in San Francisco at 20.5 cents a gallon. The price in Portland, Seattle and Tacoma is 21.5 cents.

—

Cooling Fan Problems

(*Continued from page* 967)

ally produced in automotive apparatus will not exceed from 2 to 3 pounds in 16 in., 3 to 4 pounds in 18 in., 4 to 5 pounds in 20 and 22 in. fans.

With regard to the bearing question, I believe it is a universally known fact that cup and cone bearings, as at present supplied in radiator fans, are the cheapest bearing to make and can be bought for between 8 and 12 cents each, according to size. A great many have been used, because there were no other types of fans on the market. However, the cup and cone type is disappearing rapidly, as it was the cause of the most irritating trouble and failures. Its life is short, especially when abused. To drop a fan with cup and cone bearings on the floor, or drive it with only slight force into its supporting bracket, means the destruction of the races. The same applies to ball thrusts. Plain thrust bearings with automatic adjustment according to thrust load are the most successful. In a recent test at a motor factory, the plain thrust bearing ran for 109 hours at 1500 r.p.m. *without lubricant* with only a few score marks, while the cup and cone bearing under exactly the same conditions lasted only 11 hours.

Mr. Hoyt also states correctly that not one out of ten people driving a car ever oils the fan. They will much less adjust stuffing boxes, especially when these stuffing boxes require special size wrenches and are most inaccessible. On adjustable stuffing boxes you will find invariably the felt squeezed out between shaft and stuffing nut, thus providing a wig oiler to drain the oil to the outside.

Self-contained felt arrangements on the inside of the hub, which throw the oil which they wipe off the shaft back into the bearing, are the only successful type and most simple.

The radiator cooling fan, the most important cooling unit, the highest speed part and at the same time the most neglected one on any automotive apparatus, must be built simple, rigid, foolproof and free from delicate adjustments (which will never be made) to give continuous and carefree service.

—

Truck Sales Managers Will Meet in July

DETROIT, April 28—The National Association of Motor Truck Sales Managers will meet here the latter part of July, as decided at the quarterly convention of the organization held in Philadelphia last week. The date of the Detroit meeting will be given out later.

Haste in Presentation of Claims Urged

Machinery for Settlements Temporary—No Statements Received by Ordnance After May 15

DETROIT, April 28—Approximately 70 per cent of war claims in the Detroit district are still unpaid. Aircraft and ordnance contract adjustment officials, whose organizations have been in operation 5 months, say it will be months before final settlement of all claims is made. The boards are now devoting their attention to hurrying the contractors into presenting their claims in proper form before May 15. Whether all claims will be in the hands of the boards by that date is a serious question and it is becoming more and more apparent that unless some of the big contractors speed up and file at once, they will be obliged to seek redress in the Court of Claims at Washington.

Of the 1500 claims coming under the jurisdiction of the Aircraft Board, 200 are still out. Packard, Lincoln, Ford, Fisher Body, Wilson Body, Willys-Overland, Buick and Cadillac are among them. Trouble in securing proper information from sub-contractors is given as one cause of delay in the presentation of these claims. It is estimated that only 30 per cent of all aircraft claims submitted to Washington for final approval have been paid. A large number of claims have been in Washington six weeks but no word as to their final disposition has been received.

Ordnance officials say 86 of their total claims have been filed. Fifty per cent of these have been passed upon by the Detroit board, but only 35 per cent have been approved at Washington. The Ordnance Board will receive no more claims after May 15. The Bureau of Aircraft Production claims officials have received no specific orders to refuse claims filed after a certain date. This board is urging contractors to file between May 15 and June 30, as after June 30 the board will be unable to promise immediate action. In a letter to Ordnance Board officials, Benedict E. Crowell, acting Secretary of War and Director of Munitions, declares that claims must be presented prior to May 15, as the present adjustment organization may not be in existence after that date.

He states: "It is nearly five months since these organizations were set up, and since their machinery was available for the process of adjustment. Nevertheless claims aggregating nearly one half of the total amount of money involved have not yet been formally presented. The organization which is handling this matter is essentially civilian in character and composed of men who have come into the department merely for the purpose of the war and who remain in this work only at a great personal sacrifice and at the urgent request of the department.

"I do not feel that I can continue indefinitely to impose that hardship and have determined that all contractors who desire to avail themselves of the existing organization in the department for the settlement of their claims must present them prior to May 15, as after that date the method of handling the claims will necessarily be changed owing to the impossibility of continuing the present personnel."

Both boards are making 50 and 75 per cent settlement in certain cases. When a contractor is hard pressed for money and when a preliminary inspection convinces the officials that the claim has been properly executed and is probably correct, an advance settlement of half or three quarters is made, the remainder being paid if the claim is found correct.

—

Attempt to Standardize French Tires

PARIS, April 15—At the present moment a vigorous attempt is being made to reduce tire sizes to the following: 815 x 105, 880 x 120, 935 x 135 and 955 x 155. In addition there will be one size for small light cars, but it is not certain whether this will be 710 x 90, 765 x 90 or some size which will interchange with the Ford. It is felt that five pneumatic tire sizes are sufficient to cover the entire automobile field. Michelin is using all its influence in favor of these sizes and is offering advantages in price on these standard sizes.

—

F-5-L Flying Boat Makes 20-Hour Flight

WASHINGTON, April 26—An F-5-L naval seaplane carrying Lieutenant Commander H. B. Grow and three ensigns made a non-stop flight covering a distance of 1250 miles in 20 hr. 10 min., establishing an American record for time and distance in that type machine. The machine was equipped with two 400-hp. Liberty engines, and made an average speed of 60 m.p.h. The flight was made at the Hampton Roads naval base and the distance covered equalled that across the Atlantic from Newfoundland to the Azores, the expected transatlantic route.

Although unsurpassed in America, a 24-hr. record was made in Germany before the war. Boehm, starting from the Johannisthal field, outside of Berlin, made a non-stop flight in a seaplane lasting 24 hr. 12 min., on July 10, 1914, but covered only two-thirds the distance. An H.S. seaplane, with full naval equipment, on regular patrol duty off Queenstown, Ireland, made a flight lasting 9 hr. 37 min., which stood as the record until this latest 20-hr. achievement.

—

Aviation Insurance Risks Undertaken by English Company

LONDON, April 18—The Aviation Insurance Association, an insurance organization controlled by a committee representing Lloyds, the Eagle Star and British Insurance Dominions Insurance Co. and Excess Insurance Co., has been formed to underwrite the specific risks incurred in flying. The risks include:

damage to aircraft or from other aircraft, damage to cargo, accidents to anyone in the machine or to persons or property on the ground injured by articles falling from the aircraft. This is the first time that aviation insurance has been placed on the level with other forms of insurance. A fixed tariff has not yet been established, but a schedule of rates is being prepared which will not be as prohibitive as flat rates would be.

Another English aviation insurance scheme has developed through a pool of 31 English insurance companies. In view of the heavy risks, the combined resources of the whole group will stand behind any of the policies issued by the individual companies.

Ballot Cars for Indianapolis

PARIS, April 28—(*Special Cable*)—Four Ballot cars comprising the Thomas team sailed from Paris on the Savoy on April 26 on their way to Indianapolis. These cars are to be driven by René Thomas, winner of the 1914 Indianapolis race, Albert Guyot, Louis Wagner and Bablot.

These four machines are special racing mounts which have been designed, built, tested and shipped in 90 days. They were designed by Henry, designer of the Peugeot cars. These cars are fitted with 8 vertical cylinders of 74 by 140 mm. bore and stroke. This number of cylinders has been selected because of the special conditions at Indianapolis, where rapid acceleration is an essential quality. The entire design was laid out with Indianapolis conditions in view.

The Ballot Co., responsible for these machines, is the leading engine manufacturer in France. Before the war it introduced engines only to the requirements of automobile assemblers. During the war the firm has been engaged in the production of aviation engines and special engines for lighting sets, pumps, machineshop trucks, and other similar products.

It was not until Dec. 24, 1918, that the Ballot Co. decided to enter for the Indianapolis race. Actual designing did not begin until Dec. 27. The four Ballot cars will remain in America for about 4 months after the Indianapolis race.

Coatalen Arrives with Sunbeams

NEW YORK, April 28—Louis Coatalen, managing director and chief engineer of the Sunbeam Co., England, arrived here this morning bringing with him the two racing Sunbeams which are to make their appearance at the Indianapolis track on May 31, driven by Dario Resta and Jean Chassagne. Mr. Coatalen expects to return to England as soon as possible after the race.

Stewart-Warner Doubles Profits

CHICAGO, April 28—Net profits of the Stewart-Warner Corp. for the first quarter of 1919, ended March 31, were $549,653, against $227,582 for the same period of 1918.

Reliability of Aerial Transport Essential

English Aerial Transport Committee Sees Only Limited Business Under Present Conditions

LONDON, ENGLAND, April 1—Since the signing of the armistice innumerable forecasts and articles on commercial flying have appeared in the press, mostly inspired by those at the head of the airplane manufacturing business, who are faced with the problem of finding an outlet for their production.

The majority of these have taken a rather optimistic view of the prospects. In spite of this everything to-day points to post-war aerial industry being carried on by only those firms having substantial and large interests in some business other than aircraft, which will serve them as a means of support in the event of their not getting sufficient contracts in the aeronautical line to keep their heads above water.

When the Civil Aerial Transport Committee was formed to propose to the Air Ministry the steps to be taken, the tone of its report was in strong contrast to some of these expansive predictions. That portion of the text which was made public stated that while the committee was of the opinion that the carriage of mails, and in some cases passengers also, besides certain kinds of light merchandise, might be successfully developed, the total amount of business in sight along these lines would be incapable of absorbing even a small portion of the present output in its highly developed condition.

From the pilots', and in fact from everyone's point of view, reliability is the primary essential in an airplane, and so far, though many statements have been made to the contrary, the present-day type of airplane is far from being what one might term thoroughly reliable.

In order to attain reliability, what is most needed is that the engine should have a margin of power. This means that with the engine running smoothly at about half throttle, and consequently undergoing no appreciable strain, the airplane should maintain both its forward speed and its height. Even a motor car engine, which is far heavier and more substantialy built, could not be expected to last long were it run constantly on full throttle, as is the case in an airplane.

So far no airplane engine has been produced which pretends to yield any appreciable margin of power, and until such an engine is put on the market it is scarcely worth while to consider the question of aerial transport from a commercial point of view. Further, it is hardly too drastic to say that the expenditure in overhauls, crashes, etc., would be so great as scarcely to allow any appreciable profit to be realized.

On the other hand, as regards mail carrying over long distances, and to a certain extent passenger carrying, there appear to be great possibilities, even for the present-day type of machine.

Over short distances, such as from London to Liverpool, it remains for the private individual to choose as to whether he is going to send his letters by train, which takes 5 hours, but is infallible, or whether he is going to send them by airplane and pay probably 8 or 10 cents more, which takes about 2½ hours, half as long as the train, but about one-sixteenth as reliable. Where long distances, such as from England to India, are involved, airplanes will prove to be invaluable.

It is impossible for any large firm to rely solely on aircraft production at the present time for its subsistence. The Government has many more airplanes than it knows what to do with at the moment, and the life of an airplane will be considerably long under peace conditions.

8 Uniontown Entries

UNIONTOWN, PA., April 28—Before appearing on the Indianapolis speedway on May 31, a number of the speed cars and their drivers will start the season on the track here on May 17. Among them are two Roamer specials and three Hudsons. Cliff Durant will drive his Chevrolet special. No foreign entries for this event have yet been sanctioned. Those already scheduled are:

Driver	Car
Louis LeCoq	Roamer special
Kurt Hitke	Roamer special
Eddie Pullen	Hudson special
Ira Vail	Hudson special
Harold Simmons or J. R. Hogan	Hudson special
Cliff Durant	Chevrolet special
Wilbur D'Alene	Duesenberg special
Dennie Hickey	Stickel special

Indianapolis Entry List Lengthens

NEW YORK, April 29—A third Peugeot has been entered for the 500-mile Indianapolis event for May 31, to be driven by Arthur Klein. Barney Oldfield, although out of the racing game himself, is putting his old racing car, the Oldfield special, into the hands of Roscoe Sarles for the occasion. The complete list of cars and drivers officially entered with the Contest Board of the American Automobile Association includes:

Drivers	Cars
Clifford Durant	Chevrolet special
Dario Resta	Sunbeam
Jean Chassagne	Sunbeam
H. C. Simmons	Hudson special
J. M. Reynolds	Hudson special
Eddie Pullen	Hudson special
W. W. Brown	Richards special
Eddie O'Donnell	Duesenberg special
Wilbur D'Alene	Duesenberg special
Tommy Milton	Duesenberg special
Kurt Hitke	Roamer-Duesenberg
Jules Goux	Peugeot special
Ray Howard	Peugeot special
Arthur Klein	Peugeot special
Louis LeCocq	Roamer special
Ralph DePalma	Packard special
Earl Cooper	Stutz special
Ralph Mulford	Frontenac special
Louis Chevrolet	
Denny Hickey	Stickel special
Arthur Thurman	Thurman special
Elmer P. Shannon	Mesaba special
Eddie Hearne	Durant special
Roscoe Sarles	Oldfield special

Feb. 23-Mar. 6 — Birmingham, Eng. British Industries Fair.

TRACTOR SHOWS

May 6-12—Sacramento, Cal. Sectional Tractor Demonstrations, Demonstration Field.

June 8-14—Denver, Col. Sectional Tractor Demonstrations.

July 14—Wichita, Kan. Automotive Committee of National Implement Assn.

Aug. 18-22—Aberdeen, S. D. Sectional Tractor Demonstrations.

October—Ottawa, Ont., Can. Interprovincial Plowing Match and Tractor Demonstration.

RACES

May 1—Atlantic City, N. J.—Airplane races — Aeronautic Convention.

May 3—Atlantic City, N. J.—Airplane races — Aeronautic Convention.

†May 17—Uniontown, Pa., probably 112½ miles.

May 30—Atlantic City, N. J.—Airplane races — Aeronautic Convention.

†May 31—Indianapolis, Indianapolis Motor Speedway Assn., 500 miles.

*June 14—Sheepshead Bay, L. I. Speedway race.

July 4—Atlantic City, N. J.—Airplane races — Aeronautic Convention.

*July 5—Cincinnati, O., Speedway.

*July 19—Uniontown, Pa. Speedway race.

*July 26—Sheepshead Bay, L. I. Speedway race.

*Aug. 15—Middletown, N. Y. Dirt track event.

*Aug. 22-23—Elgin, Ill. Road race.

*Aug. 23—Sheepshead Bay, L. I. Speedway race.

*Sept. 1—Uniontown, Pa. Speedway race.

*Sept. 20—Sheepshead Bay, L. I. Speedway race.

*Sept. 27—Allentown, Pa. Dirt track event.

*Oct. 1—Cincinnati, O. Speedway race.

*Oct. 4—Trenton, N. J. Dirt track event.

*Oct. 11—Danbury, Conn. Dirt track event.

†Sanctioned.
*Tentative dates.

CONVENTIONS

April 28-May 1—St. Louis, Mo. Chamber of Commerce of United States Convention.

May 1-June 1 — Atlantic City, N. J.—Pan-American Aeronautic Convention and Exhibition — Aero Club of America, the Aerial League of America and the Pan-American Aeronautic Federation.

May 21-24—Washington — Conference on Weights and Measures — Bureau of Standards.

May—Washington, Pan-American Commercial Conference, Pan-American Union Building.

June 2—Chicago, Ill.—Natl. Gas Engine Assn. Hotel Sherman.

June 23-28—Ottawa Beach, Mich. —S. A. E. Mid-summer Meeting.

Sept. 22-24—Philadelphia, Annual Convention, National Association of Purchasing Agents, Bellevue-Stratford.

King-Bugatti 16-Cylinder Aero Engine

(*Continued from page* 959)

The front bearing on the pump shaft is lubricated by spray from the crankcase, which collects on the shaft bushing support and drains down into a ⅛-in. hole leading to the bearing. Any oil leakage from the front end of this bearing returns to the sump, any slight leakage from the rear end of the bearing is drained outside the crankcase with the water leakage from the rear bearing.

There is one water inlet to the pump, of 2¼ in. inside diameter, while the single outlet is of 2 3/16 in. diameter. Water from the pump is forced up into an aluminum pipe with one branch leading to the rear end of each of the rear cylinder blocks, water entering the cylinders at the top of the water jacket on the exhaust side. A certain amount of the water circulates through the inlet manifold jacket, the remainder filling the cylinder water jacket space.

The propeller shaft is driven through a spur gear splined to the shaft meshing with a gear on the front end of each of the crankshafts, both crankshafts turning clockwise. The propeller shaft is hollow and is carried in three bearings, a ball bearing either side of the gear and a plain bearing at the rear end.

The front gear cover, the ball bearings and the gear are assembled complete as a unit before mounting in the engine. The ball bearings are Monarch Special Width Hess Brights, being narrower than the standard bearing. The front bearing is mounted in the gear cover and takes all the propeller thrust as well as a certain part of the radial load. The rear bearing slides into a retainer in the crankcase, being free to move endwise, carrying radial load only. The hub of the gear acts as a spacer for the ball bearings, the latter being held in position on the shaft by two nuts with a locking plate between. Mounting is such that the ball bearings and gear are easily and positively assembled, there being no danger of injuring the ball bearings by screwing the retaining nuts too tight.

Provision is made for attaching two gun control mechanisms, one at the rear end of each of the camshaft housings, driven directly from the camshafts through a slotted coupling. The tachometer drive may be taken from either end of the two camshafts. It operates at camshaft speed through a slotted coupling. When the gun control mechanism is used the tachometer drive is taken from the rear end through the same type of coupling as when driven directly from the end of the camshaft.

Timken Bearings and Spiral Timing Gears on Fords

DETROIT, April 24—The Ford Motor Co. is now supplying Timken roller bearings to Ford dealers to replace the ball bearings in the front wheels. The introduction of these bearings came with the detachable wheels, and this bearing is made interchangeable with the old type ball bearing so that the replacement can be made without changing any other parts.

The spiral timing gears which were incorporated into the design of the engine at the time the electric starting and lighting system was placed on the enclosed models have now been made standard on all the cars.

Sundstrom Now Rex Machine

CHICAGO, April 28—The Sundstrom Mfg. Co. is now the Rex Machine Co., manufacturing Rex automotive air equipment besides dies and tools.

U. S. Relaxes Cable Censorship

NEW YORK, April 28—Cablegrams from persons in the United States to Central or South America, including Mexico, Cuba and the West Indies, may now pass uncensored. The United States has also stopped censoring cable messages to or from points within British, French or Italian territory. Likewise cablegrams from all parts of the world and Central or South America are no longer censored by the United States. In addition, messages from the Far East, except those sent through Vladivostok, are not subject to American censorship.

British, French and Italian censorship, however, is still in operation, so that uncensored cablegrams from the United States are subject to the regulations of the French, Italian and British officials.

British Censorship Relaxes

WASHINGTON, April 29—Modification of British censorship, permitting the use of private code in cablegrams from the United States to South America passing through London, is announced by the Navy Department.

Mertzanoff Handles Automotive Exports

NEW YORK, April 29—C. E. Mertzanoff, formerly in charge of the export department of Mitchell Motors Co., is now acting as export manager for the American Motors Corp., Plainfield, N. J., makers of the American Six; the Seneca Motor Car Co., Fostoria, Ohio, building a 4-cylinder five-passenger car and the Piedmont Motor Car Co., Lynchburg, Va., building sixes and fours. He acts in a similar capacity for the Economy Body Sales Co., New York, makers of dump bodies for commercial cars, and the E. & W. Mfg. Co., Milwaukee.

Airplane Supply System of the American Army in France

How 46 Complete Flying Squadrons Were Organized, Equipped and Maintained

By W. F. Bradley

PARIS, April 20—Having decided that the military might of Germany should be smashed, it appealed to the imagination of the American citizen to drive home the most crushing blow by way of the air. Probably, when that resolution was taken, the great majority of the people of the United States never realized how difficult, how complicated, how full of unseen obstacles was the program they had placed before them.

The business of raising soldiers is as old as the world, and although the Kaiser and his advisers believed they had surpassed all possible competitors in this branch of activity, England first demonstrated that a healthy young manhood can be transformed into an armed force in a few short months, and the American nation on coming into the fray still further demonstrated this fact. There may be military tradition behind the Kaiser's troops, but they have had to admit themselves crushed and defeated by men who put on the uniform with no other object than to get rid of a bully.

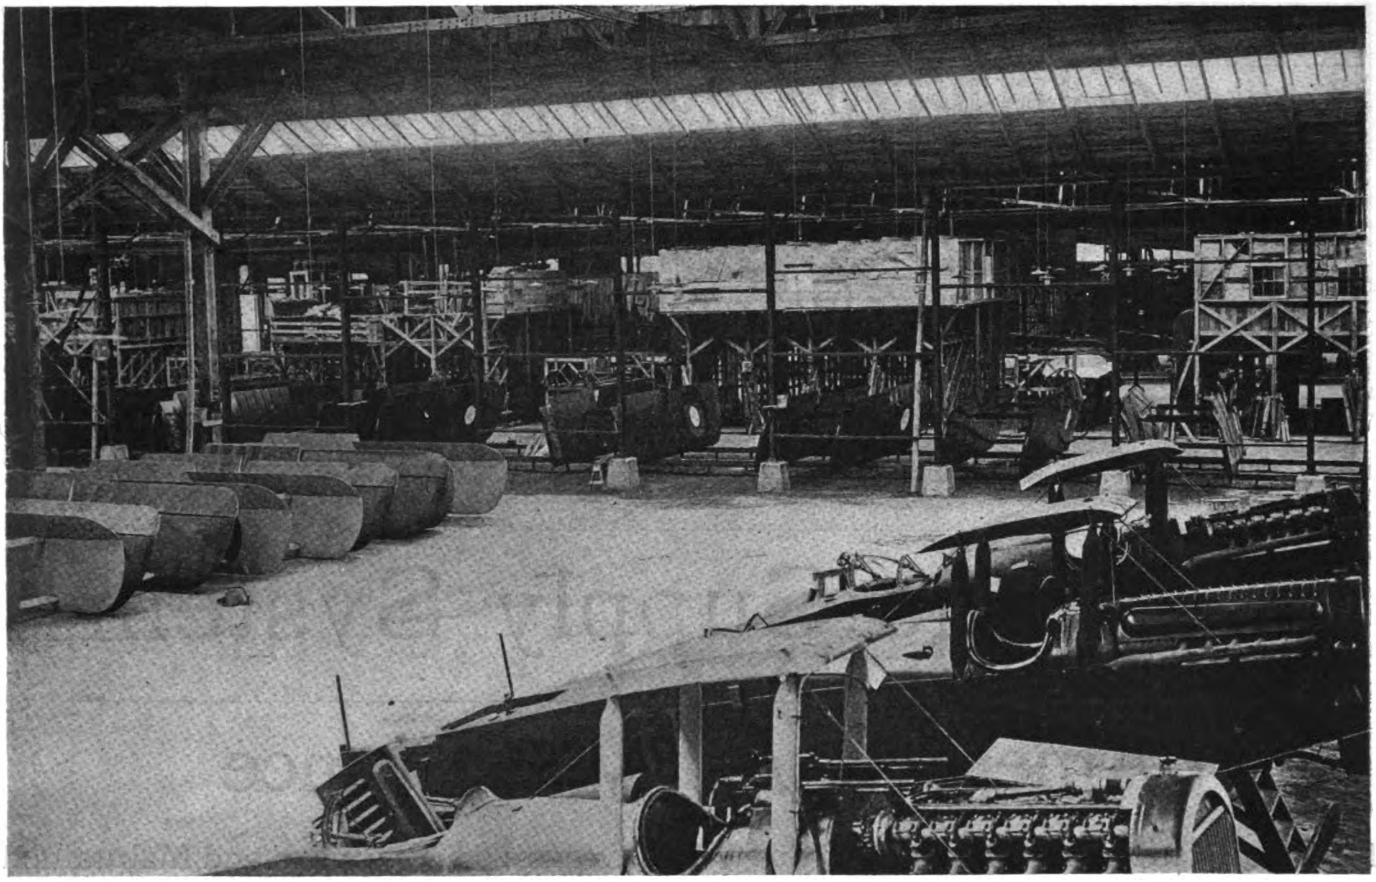
The creation of an aerial army brings up problems of an entirely different order. Teaching an army to fly is in itself a big job; but it is not by any means the biggest. A flyer needs an airplane, and America possessed none; an airplane needs an engine, and America had never built any. An airplane built to-day is out of date six months hence, so far as military operations are concerned.

This means that you cannot just sit down and copy the best available, then go ahead and produce them. While you are building you must be working on something which you know will make your present machine look like a back number. When you have got your airplanes it is necessary to learn how to use them. This lesson has to be learned while you are using them. Further, all that was ever known about the military use of airplanes has been learned since the summer of 1914.

Compared with the Allies, the task of the American Air Service was one of compound complication. The real lessons are learned at the front; they are corrected at the rear. And America was separated from the front by a distance of 3000 miles, across which communication was always

ACHIEVEMENTS OF AMERICAN AIR SERVICE

Starting right at the bottom of the ladder, with no personnel, little accumulated experience, no formulated organization, the Supply Section of the Air Service had provided for all the wants of an active air force composed of 2017 flying officers, 528 ground officers, and 29,774 enlisted men. It had constituted and sent into active service over the lines a total of 46 complete flying squadrons; it had in operation 12 squadrons of all-American planes; it had received 6476 airplanes, of which number 3261 were service planes; it had erected and put into operation, for assembly, repair, and salvage of material, workshops bigger than the largest automobile factories in the United States.



The airplane assembly shops at Romorantin on the day of the armistice

slow and often difficult. Despite all these unusual and difficult conditions, the American Army in the field was always furnished with all the aerial supplies it required. On Nov. 11 it could be shown that every requisition of the army had been met, that there was a big supply of machines in reserve to meet urgent calls, and that a huge scheme of supply had been completed which would have permitted of a tremendous increase of the flying forces of the American army.

Exceptional Achievement in One Year

At home the Supply Section of the Air Service, with little accumulated experience, tackled the problem of the aviation engine and in a little more than one year had designed, perfected, and built to the extent of 3,000,000 hp. a successful aviation motor which was operating not only over the American lines but in planes belonging to the Allied powers. During the same period the total horsepower of steamship engines built in the United States was only a fraction of the total of aviation engines. Yet steam engine production is a standardized and old-established industry, whereas previous to 1917 there was no aviation engine industry in America, and few of the men who ultimately made good in this line had ever seen a modern flying machine or engine.

To appreciate correctly the effort of America to strike at Germany through the air, it is necessary to take a stand in Paris. This may appear to be a deviation from the main track, for the great effort starts away back in the pine forests of Oregon and culminates in the Argonne, the Somme and the Chateau-Thierry district. The American line thrown across the Atlantic and striking the

French coast at Bordeaux and Saint-Nazaire continues in a northeasterly direction across the center of France, leaving Paris a considerable distance to the north. The headquarters from which the main stream of supply was directed to the American army was established in the town of Tours. Yet the Air Service supply organization abandoned Tours and went over 100 miles further north to the French capital.

French Machines on Original Order Never Delivered

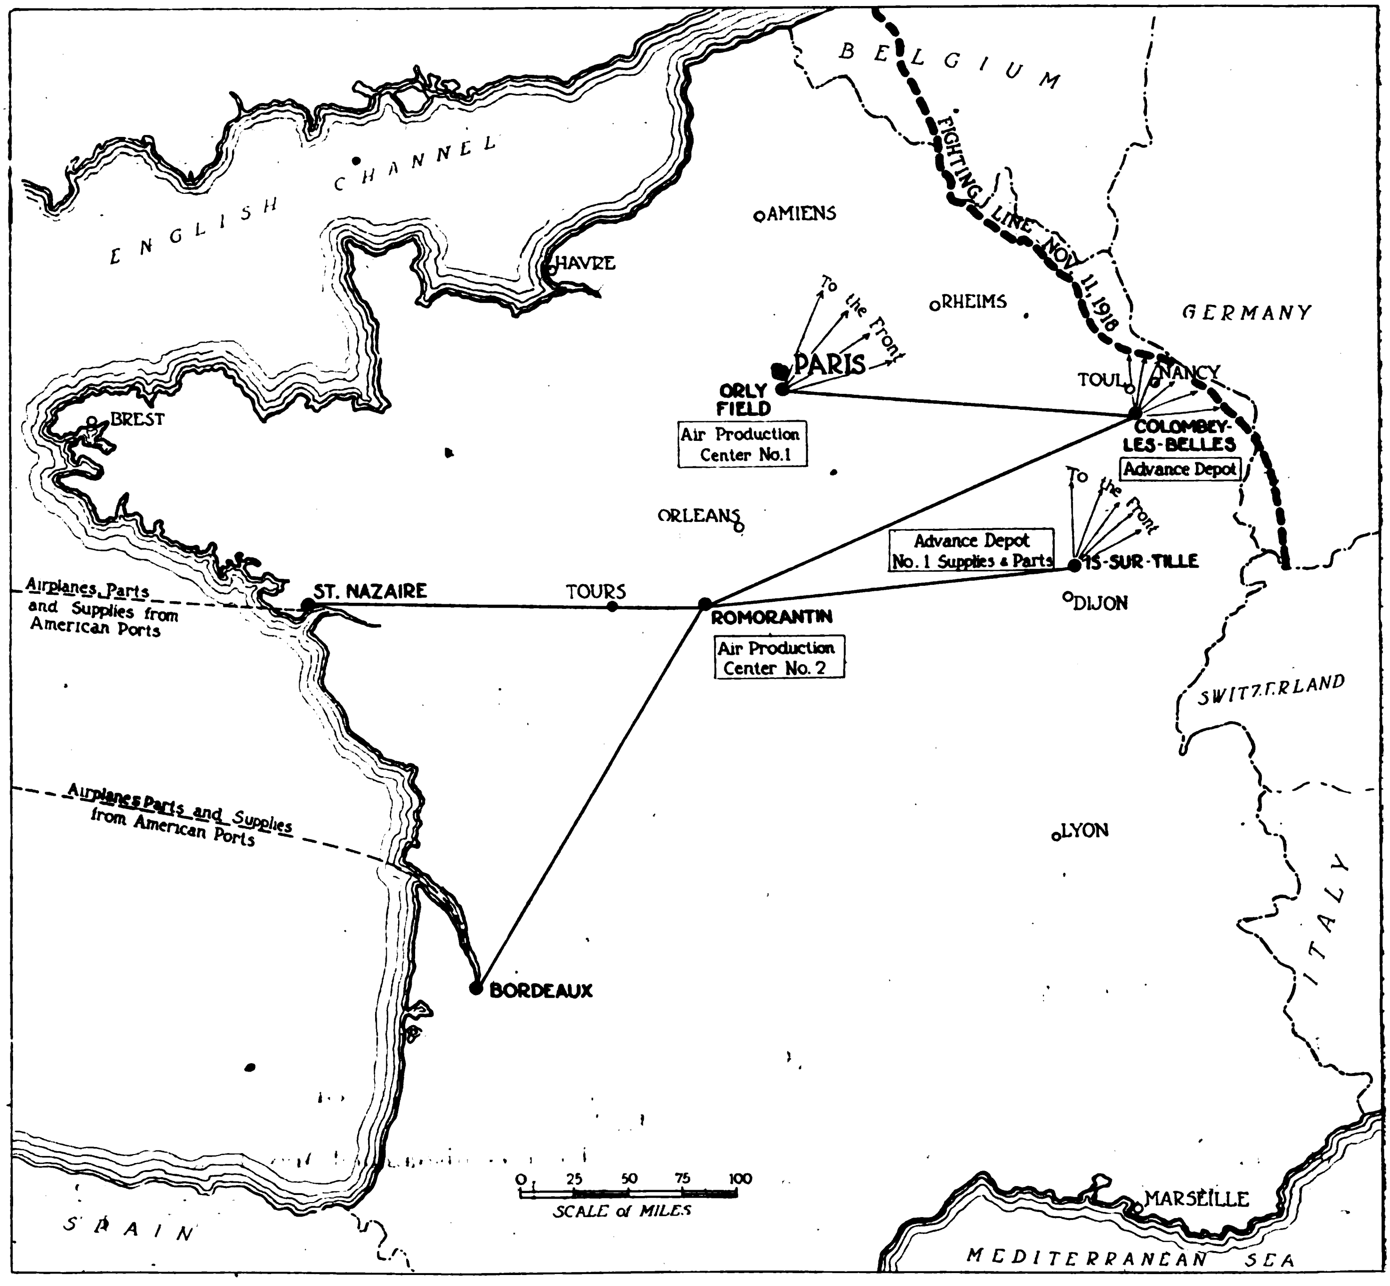
The activities of the American Air Service in France date back to the summer of 1917, when the Bolling Mission arrived in Europe. At that time the American effort was nebulous; it was striving to assume a concrete form, to evolve itself into a powerful working organization. At the end of about three months the Bolling Mission ceased to exist, after having placed a contract in Europe for 5000 airplanes, and having made clear to itself, and probably to the authorities at Washington, the great difficulty of the task of creating a big aerial force.

The 5000 machines France was to supply to the American army never materialized. Nobody is specifically to blame for this, for if America was slow in providing the raw and partially finished material she had to furnish under this contract, the French at that time showed a lack of faith in the American effort. They, who had been through the mill, knew the enormity of the task and were well qualified to estimate the length of time which would be necessary for America to bring an aerial force into existence.

Creating an American Air Force

Meanwhile America was working, but when the year 1918 opened the fact had to be faced that the American program was a long way behindhand, and that practically no supplies were being received from European sources. The mistake had been made at home of overestimating the speed with which an aerial force can be created. There are natural limits to all developments,

(Continued on page 1013)



Map of France, showing how the American army was supplied with airplanes from two production centers, Orly, at which foreign-made machines were assembled, and Romorantin, where the all-American planes were produced. The airplanes were flown from these points to the front through advance depots near the fighting line

Business Needs Leadership and Government Co-operation

Many Problems Unsolved—Centralized Government Departments Necessary for Foreign Trade—Railroads and Merchant Marine Under Private Owners

THE UNITED STATES CHAMBER OF COMMERCE CONVENTION AT ST. LOUIS

By Allen Sinsheimer

ST. LOUIS, May 1.—Concrete suggestions for return of the railroads to their owners and for sale and distribution of the merchant marine to Americans and positive governmental acknowledgment that the anti-trust laws are antiquated and not in accord with modern business needs were the most important developments of the U. S. Chamber of Commerce convention at St. Louis.

The convention included more than sixty speakers on eighteen major and forty related problems, and the great majority offered problems and acknowledged obstacles to industrial growth, while but few stated concrete recommendations for them. It was a statement heard frequently that either many of the problems do not exist and consequently have no solution, or there is a need for business leaders who can step forward now and guide the nation through its post-war infancy.

That the government must recognize the necessity for new legislation and for greater co-operation with industry because of the after-war conditions was said to be the vital need of business at this time.

Effect of War on American Business

Government action is necessary for new legislation that will fit the new era of our business history and for new departments to meet the new needs of industry.

America's entrance into world trade is producing closer industrial, commercial and diplomatic contact with foreign nations, and new government departments and policies must provide ample assistance to our manufacturers so they can overcome all problems abroad that usually come within the province of government.

That no solution can be found to the problems of business and that they are numerous and each vitally important were other developments of the sessions. Every speaker acknowledged that a new era of business history is before the nation, and demanded complete revision of policies, organizations and perspectives from government, capital and labor.

WE paid three billion dollars for our Marine during the War. The British Marine cost a little over one billion dollars. The entire Merchant Marine of the World cost two billion dollars. It is absolutely necessary that a considerable portion of the cost of our Marine be written off, if our ship owners are to compete abroad.—HOMER FERGUSON, *President, Newport News Shipbuilding Co.*

A COUNTRY starting out on the all-tax theory has been taught by experience that it was impossible for them to raise the funds required without recourse to huge loan operations, and then conversely the "all-loan" champions amongst the nations found that it was foolhardy and suicidal to try to finance a war without raising a large portion of its cost by increased taxation.—PAUL WARBURG.

The growth of business and its new standard of higher business ethics must be met by the government with new laws. Combination has been replaced by co-operation and the anti-trust laws of the last century are antiquated, inadequate and obstacles to trade development. The government must recognize this by legislation, approving of co-operative associations for combinations of manufacturers, not for price-fixing or monopoly, but for scientific industrial advancement. It should extend every co-operation to business and cease its interference with business.

That the railroads should be returned to their owners as soon as legislation is enacted that will protect the public, the government and the weaker railroads, was agreed by all speakers, including Walker D. Hines, Director General U. S. Railroad Administration, Senator A. B. Cummins and others.

The American merchant marine must be sold to Americans and on a basis that will insure bottoms for every section of the country requiring them.

Organized labor, it was stated, is here to stay. There must be recognition that a union of labor is as justifiable as a corporation, which is a union of capital. Labor must be regarded as a fellow servant with capital and not as a commercial commodity. Wages are not the only factor in the contentment of labor. Good living and working conditions are equally important and sometimes more so.

Our domestic business and conditions of employment will only be stable if we develop our foreign trade. But we should not look, it was emphasized, to the Allies for

business. They need their own raw material and cannot spare the cash to buy from us. We should look for our largest export trade to South America, the Orient and the European neutral countries. We can only do export business for the next few years with the Allies if we will make investments in private and public enterprises in those countries and accept these as payment for our trade. The Allies cannot buy abroad until they can first develop and re-establish their export trade and sell abroad.

Other important points developed and recommendations made were:

That the government should pay interest on all payments of war contracts that are unduly delayed.

That a comprehensive road construction policy should be formed.

That the Industrial Board for price fixing should be encouraged.

That the Federal Trade Commission should be purely advisory.

That the government should compile a yearly budget and that governmental employees should be selected with regard to their ability to serve industry.

That there should be established a centralized government department to take over the existing fifteen agencies now connected with exports.

That there should be industrial training for labor.

That there should be active participation by commercial bodies for securing employment for returning soldiers.

That the education of the American public to the value of foreign trade, to the importance of making investments abroad, and to the reasons why we cannot now look to the Allies for development of our export business should be vigorously carried out.

Resolutions were considered by the convention for appropriation for industrial training, a business cabinet for the President, a centralizing agency for all government bureaus concerned with foreign trade, cost accounting by the government, reorganization of the Federal Trade Commission, continuation of the Industrial Board for price fixing under George Peek, for the payment of interest on overdue government payments, and for new forms of blanks for federal taxation, all of which were referred to the new board of directors of the Chamber for further consideration and action.

Resolutions passed included:

a—Revision of federal laws dealing with business to clearly define rights, limitations and obligations.

b—Employment of soldiers, sailors and marines in the community where they were employed prior to entering the service.

c—New legislation necessary to safeguard our social and business structure during the readjustment from war to peace.

THE government has no justification for attempting to run the business of others until it can run its own business successfully.
—GOVERNOR EDGE, *New Jersey*.

WHAT BUSINESS ASKS OF THE GOVERNMENT

LEGISLATION that will approve of associations of manufacturers into combinations for the purpose of developing and improving industry, which in turn means abolition of such laws as the Sherman Act, which is declared antiquated and not in keeping with the standard of ethics of modern industry.

Reorganization of the Federal Trade Commission to form a larger and purely advisory body.

Sale of American merchant marine to Americans and on a basis that will insure fair distribution of bottoms to every section of the country needing them. Prices of sale to be below the war cost of the ships to allow ship owners to compete with foreign trade.

Modification of sea laws to allow all officers of the American marine to be Americans.

Government subsidy for ship owners if necessary.

Special bureau under Department of Commerce for water transport.

Centralized department that will co-ordinate the work of the fifteen bureaus now handling various details of foreign commerce.

Establishment of Federal Highway Commission, federal appropriations for the construction and maintenance of national highways, federal road building aid for the states beyond 1921, federal approval for road construction when the roads are of a permanent character only.

Compilation of a yearly budget of government expenses and financial condition.

Greater exercise of care in the selection and appointment of government employees who work in bureaus that co-operate with or aid business.

Return of railroads to their owners after Congress formulates legislation providing for a consolidation of railroads into competing combinations comprising both weaker and stronger roads and to protect the public, the government and the owners.

A vigorous, aggressive policy that will enable our exporters to meet and overcome all obstacles abroad whether of a commercial or diplomatic nature.

Revision of laws to clarify them so all manufacturers can know their rights.

COLLECTIVE bargaining is here to stay.—WILLIAM C. REDFIELD, Secretary of Commerce.

YOU can't man the work unless you house the man.—WILLIAM S. MILLENER, Manager, Williamsport, Pa., Board of Trade.

d—Objection to the entrance of the Government into any field of transportation, communication, industry or commerce or any business that can be successfully undertaken and conducted by private enterprise.

e—The extension of banking and insurance under government supervision to encourage foreign trade

f—Development of a policy for protection of American citizens, enterprises and investments abroad to encourage foreign investment and stimulate export trade.

g—Return promptly of the telegraph and telephone properties to their owners.

h—Creation of a federal highway commission, substantial appropriations for construction and maintenance of a national highway system, continued federal road aid to states beyond 1921 and government approval for highway construction only when the roads are of a permanent type.

i—Development of a comprehensive system of waterways to co-ordinate the waterways and railways of the country.

j—Conservation of the water power resources of the United States.

k—Establishment of a national budget, to be compiled yearly and to simplify government expenditures and provide economy.

l—Power to the President to veto any separate items or provisions contained in an appropriation bill.

That the railroads should not be returned to their owners until legislation to safeguard them has been passed by Congress was urged by Walker D. Hines in a comprehensive speech in which he outlined a definite plan for their return. He agreed, he stated, with the other speakers that it is to the best interests of the nation that the railroads be operated under private ownership.

As a permanent solution to the problem he stated that the railroads should have a fair return on the fair value of their property, and this value must be determined before legislation is passed. With 180 railroad companies operating generally at the same rates regardless of cost of operation and with many earning but 2 per cent and others as much as 10 per cent, it is clear, stated Mr. Hines, that the legislation must provide for protection to the weaker road. Mr. Hines analyzed the subject further.

Five propositions in all enter into the railroad problem: First, the absence of standards of rates, etc.; second, the wide disparity between the weak and the strong roads; third, the absence of any point of contact between the government and the private management; fourth and fifth, the public suspicion of over-capitalization and fear of exploitation.

All of these can be overcome by a compulsory consolidation of the railroads into a few large competitive systems with from twelve to twenty combinations in the three great sections of the country, the West, East and South. Each system or combination should combine the strong and weak roads to secure a fair average in the general situation. There should be an official capitalization. There should be arrangements for government representation on the board of each combine. There must be compulsory combination to insure that the stronger roads combine with the weaker ones. A plan of this kind, properly framed by Congress, will allow the return of the railroads to their owners without hardship or loss to the government, the public or the owners.

Union Labor to Stay.

Union labor is here to stay, and the anti-trust laws are antiquated and obsolete and a direct obstacle to the development of American industry, said William C. Redfield, Secretary of Commerce. Business has outgrown the laws intended to control it, he stated. American business of the future will be more co-operative than competitive.

"Nothing is more certain," he said, "than that there has been a great change for the better in the ethics and methods of trade since the anti-trust laws came into being. There are few elements of good in a strictly competitive state of business. If competition is the life of trade, in its extreme form it may also be the death of trade. If we attempt to end monopoly by insisting upon competition we provide that which will itself create monopoly. Laws intended to restrain trade may restrain promotion of trade. There is a new business standard whereby industry and commerce recognize three-fold obligations to the public, to the business itself and to labor, and industry is frankly endeavoring to adjust itself to these and must have government assistance. We cannot keep the new wine of trade in the old bottles of law.

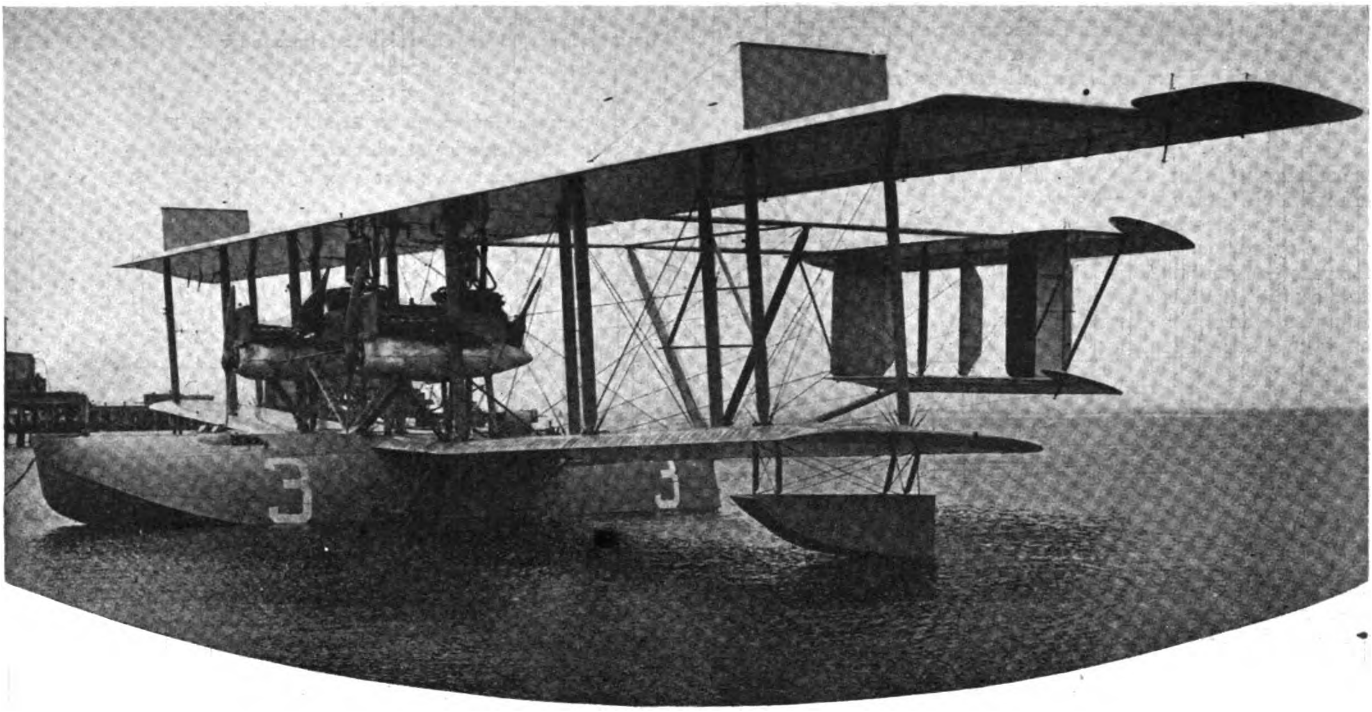
"With the new ethics of trade has come an altered view of labor, now recognized as the fellow servant and not as a commercial commodity. Collective bargaining is here to stay, and a corporation, which is a union of capital, it is now recognized, is no more or less justifiable than a union of labor.

"There is open to us a new course taking advantage alike of the strength of competition and combination and lacking the weakness of both. It is co-operation, within the industry and from the government. We do not have to look very far to see clear signs of the coming of this thing I have called co-operation. The Webb Law

(*Continued on page* 1022)

THE middleman is the specialized distributer of commodities between the producer and the consumer and his function is a product of normal and natural industrial development. He is a necessary link in the chain which reaches from grower or producer to consumer.—DR. W. F. GEPHART, Washington University School of Commerce.

THE war has brought an understanding of the present immediate need of highways development. The co-operation of towns, counties and states to build roads to form a national highway from coast to coast is needed and will be of the greatest advantage to the community as well as the entire country.—T. M. DUFFEY, Indiana Highway Engineer.



Navy Planes Ready for Ocean Flight

Heavy Head Wind Delays Departure—Fire Damage to Two Machines Repaired Within 24 Hours—Technical Details of the Planes

ROCKAWAY, N. Y., May 6—Unfavorable weather conditions prevented the start of the three NC flying boats on the first leg of their transatlantic trip which had been scheduled for early this morning with the proviso "weather permitting." A 30.5 mile an hour wind was blowing, and as it was an almost direct head wind it would have greatly retarded the progress of the machines. The distance of this first stage of the proposed route, to Halifax, is only 540 miles, and with a head wind of 30 miles per hour not much over 35 m.p.h. actual flying speed could be counted on, which would have made the time required for the flight 15½ hr. Commander Towers explained that the center of high pressure, which had been at Chicago, and the eastward progress of which they had counted upon to assist them toward St. John's, the final "jumping off point," had moved with much greater speed than expected and any advantage that might have been gained from it was lost. The decision not to make the start to-day was based not only on the weather conditions at the point of departure, but on weather reports from points all along the proposed route which were received via Washington.

A gasoline blaze in the hangar housing the big machines early yesterday morning came near seriously delaying the start of the enterprise. While some of the enlisted men were filling the fuel tanks of one of the machines some gasoline spilled on the floor suddenly caught fire, and the blaze was communicated to the left-hand wings of the NC-1, which were damaged to such an extent that they had to be replaced. While the blaze started suddenly, and no one seems to be able to give a positive explanation of its origin, the supposition is that a spark produced in the wiring or at the commutator of an electric motor used in pumping the "gas" into the tanks of the planes was the cause. The damaged wings of the NC-1 were replaced by the corresponding wings of the NC-2, a machine that has been used mainly in experimental work and which it was not intended to fly across the ocean. The NC-4 had its tail surfaces damaged by the fire, but the framework of the tail planes was not weakened, hence a repair could be made by simple recovering, which was done with great dispatch.

At dawn this morning the NC-1 was at the water's edge, apparently ready to start off at a moment's notice. The NC-4 was standing some distance back, in the open space between the two immense hangars which have been housing the "transatlantic" planes, and all of its engines were belching flame, evidently undergoing a tuning-up process. The NC-3 was inside one of the hangars and a crew of mechanics was just completing the installation of a new port-side engine, the original engine having developed a loose bearing.

Ocean Flight Planned in 1914

Last night, when it was expected that the start would be made the first thing this morning, one of the newspaper men assembled at the air station put a number of questions to Commander Towers in connection with the proposed trip. To the question as to whether he considered the work in the line of his regular duty, as a patriotic task or as work done in the interest of science, he said that he regarded it as in the nature of special duty. The Navy, which had been planning for the trip since 1914, had launched the enterprise for the scientific and technical data it promised to furnish. Asked as to whether he would want to make a prediction as to the outcome of the trip, Commander Towers said that he had been in the Navy too long to pose as a prophet; however, if the painstaking work of all those who had been engaged in preparing the planes for the long flight counted for anything, the attempt certainly should lead to success.

This morning, just before it was announced that the start would not be made to-day, a telegram was received by

Commander Towers at the Rockaway air station from Secretary of the Navy Franklin D. Roosevelt, reading as follows:

"Congratulations on speedy repairs. The Navy wishes you and your officers and men all success in this first organized effort to cross the Atlantic in air. I wish I were with you. Good luck."

As indicated, three planes have been prepared for the transatlantic flight, the NC-1, NC-3 and NC-4. In this designation NC stands for Navy-Curtiss, the design being due to co-operation between the aircraft engineers of the Navy and of the Curtiss Aeroplane Company, and the machines having been built at the Curtiss experimental plant in Garden City, L. I. Each plane is equipped with 4 high-compression Liberty engines.

The standard crew will consist of five: one commanding officer who will be the navigator, two pilots, one radio operator, and one engineer. An additional member will be carried in the crew of each seaplane as far as Newfoundland, in order that minor mechanical difficulties which might occur in the first part of the trip could be quickly remedied, and, further, to provide a reserve of personnel in case of any sickness among the regular crews, while waiting in Newfoundland for the start.

The crews will be as follows:

CREW NO. 1

Commanding Officer, Commander J. H. Towers, U. S. N.
Pilot, Commander H. C. Richardson, Construction Corps, U. S. N.
Pilot, Lieutenant D. H. McCullough, U. S. N. R. F.
Radio Operator, Lieutenant Commander R. A. Lavender, U. S. N.
Engineer, Machinist L. R. Moore, U. S. N.
Reserve Pilot Engineer, Lieutenant (j. g.) B. Rhodes, U. S. N.

CREW NO. 2

Commanding Officer, Lieutenant Commander A. C. Read, U. S. N.
Pilot, Lieutenant E. F. Stone, U. S C. G.
Pilot, Lieutenant (j. g.) W. Hinton, U. S. N.
Radio Operator, Ensign H. C. Rodd, U. S. N. R. F.
Engineer, Chief Special Mechanic E. H. Howard, U. S. N.
Reserve Pilot Engineer, Lieutenant J. L. Breese, U. S. N. R. F.

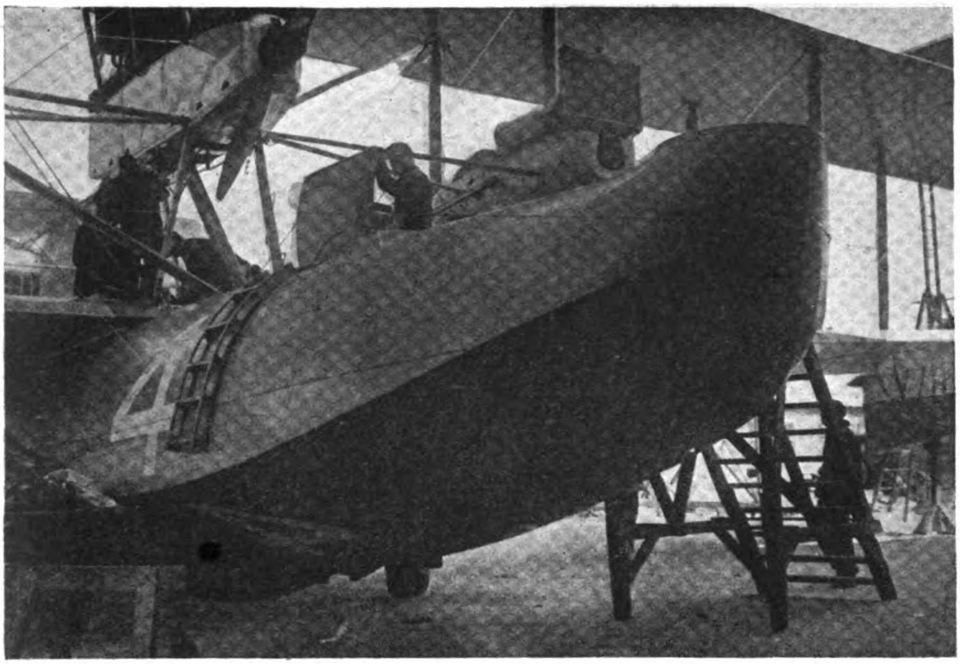
Engineer, Chief Machinist Mate C. I. Kesler, U. S. N.
Reserve Pilot Engineer, Machinist R. Christensen, U. S. N.

Lieutenant Commander R. E. Byrd, U. S. N., will go in a division commander's seaplane as far as Newfoundland in connection with special navigational experiments, Chief Machinist's Mate E. S. Rhodes will be an extra member of the crew of one of the other seaplanes as far as Newfoundland.

Itinerary of Proposed Flight

As now planned, the trip will end in Plymouth, England, and will be made in five stages. Of this the first stage, from the Naval air station at Rockaway, N. Y., to Halifax, Nova Scotia, measures 540 nautical miles in length; the second stage, from Halifax to Trepassy, Newfoundland, 460 miles; the third stage, Trepassy to Horta, Island of Fayal, Azores, 1200 miles, or to Punta del Gado, Azores, 1350 miles; the fourth stage, Horta or Punta del Gado to Lisbon, Portugal, 750 or 800 miles; the fifth stage, Lisbon to Plymouth, England, 775 miles. The actual transatlantic flight will be from Trepassy, Newfoundland, to Lisbon, Portugal, and no great effort will be made to get to Trepassy as quickly as possible. Whether the stop in the Azores will be made at Horta or Punta del Gado will depend upon weather conditions when these islands are reached. It is figured that an average speed of 65 nautical miles per hour can be maintained, irrespective of wind conditions. Arrangements have been made to have base ships with the necessary gasoline, oil, etc., at the various ports en route, and these ships are provided with special equipment so that refueling can be accomplished quickly.

Some of the chief specifications of the NC boats have already been published in AUTOMOTIVE INDUSTRIES. These machines have a span of 126 ft.



Forward end of hull, showing navigator's pit

from wing tip to wing tip for the upper wings and 114 ft. for the lower, there being a 6-ft. projection of the aileron on each side. The width of the wings is 12 ft.; the gap, 14 ft. at the center and 12 ft. at the outer tips of the lower wings. The overall length from front end to rear end is 68 ft. 3.5 in., while the length of the hull is 44 ft. 9 in.

The weight of the plane, empty, including wireless installation and all navigating instruments, is 15,100 lb., while in flying condition, with full load, the weight is 28,500 lb. This makes the load per unit of wing surface approximately 12 lb. and gives a ratio of useful load to total load of 47 per cent. It is estimated that when carrying full load the boats can develop a maximum speed of 79 nautical miles per hour and at light load 84 nautical miles per hour.

Fuel is stored in 10 tanks, of which 9 are built into the hull and one is in the upper wing above the hull. Each of the tanks in the hull has a capacity of 200 gal., and the gravity feed tank in the upper wing has a capacity of 90 gal., making the total capacity equal to 1890 gal., which is equivalent to 11,400 lb. Disregarding the effect of the wind, this gives a cruising radius of 1476 nautical miles. Lubricating oil to the amount of 900 lb. is stored, and the crew and provisions make up about 1000 lb. of additional load. Each crew consists of 5 men—two pilots, 1 navigator, 1 wireless operator and 1 engineer. The gasoline tanks are of aluminum and the fuel piping is partly of aluminum and partly of copper. The weight of the gasoline system is 6 lb. per gallon of gasoline carried. The engines weigh 825 lb. each and the weight of the empty hull is 2650 lb.

Small Wooden Propellers Drive Gasoline Pumps

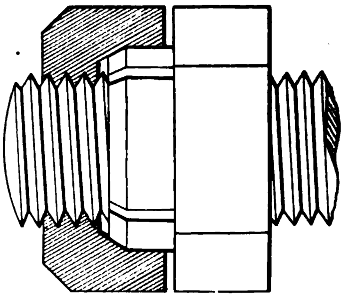
The ailerons have an area of 265 sq. ft.; the stabilizers, 267.6 sq. ft.; the elevators, 240.1 sq. ft., and the rudders, 69 sq. ft. The wing tip pontoons weigh 95 lb. each and have a displacement of 1800 lb. each. Small wooden propellers are used for driving the gasoline pumps, and the electric generator used to furnish current for ignition, etc., is driven by the same means. The gasoline pumps are in duplicate, and in addition a hand-operated auxiliary pump is provided. The current from the generator is fed to storage batteries. In addition to furnishing current for ignition the generator also supplies current for operating the wireless set, a complete lighting system for the interior of the boat and for wing tip and tail lights, as well as for lights for night landing. The wireless operator and engineer are located in the main after-compartment just aft of the gasoline tanks. Each is provided with a complete instrument board and each has a cylindrical upholstered stool, with back rest, weighing 5 lb. complete, within which can be stored the small hand tools required for emergency work.

The pilots are in the hull just forward of the gasoline tanks. Complete sets of instruments are provided, including one compass for each pilot. Flying control is by the dual Deperdussin system, with side-by-side seating. The navigating station is in the front end of the boat hull, and the navigator is provided with a chart board, charts and ordinary navigating instruments, including compass and sextant. A complete wireless installation, including a telegraph, a telephone and a wireless direction indicator, is provided. The sending radius is approximately 300 miles while in the air and 100 to 150 miles while in the water.

The main structure of the hull and wings is of western spruce, and most of the metal wing fittings and structural fittings are of chrome-vanadium steel, with an ultimate strength 150,000 lb. per square inch. All flying, landing and control wires are standard woven aeroplane cord wire. The wings are covered with linen and are treated with the regular fabric dopes. Streamlining forms of Micarta are used on the wing struts, while the landing and flying wires are streamlined with rubber covered with rubberized fabric. The main keels of the boat hulls are of oak or rock elm, while most of the hull structure is of spruce and the planking of spruce or cedar. The turtle back covering is of cedar or of cotton wood-birch 3-ply veneer.

The Drake Lock-Nut

An improved lock-nut has been designed by George F. Drake of San Francisco and is being manufactured by the Drake Lock-Nut Co., Cleveland, Ohio. The illustration herewith shows a cross-section of the lock-nut on a bolt, illustrating its principle and application. It will be noted that there is an ample wrench-hold to turn up the nut and pull the work into place. After this has been done, the upper locking member is turned down, and, the contact occurring on a 25 deg. angle at the top of the boss, which is made flexible by slotting, the lower member is securely locked on the bolt at the point of adjustment first obtained, without transferring the load from the lower member to the upper member.



This is explained by the fact that the two members never contact or seat in a horizontal plane at the bottom or top of the boss. The seat or contact occurs on the annular bevel at the top of the boss, and the interior annular bevel in the upper member. The bevel being 25 deg. (and in larger sizes 20 deg.) the radial component of the pressure between the two members will be much greater than the axial component. This results in the flexible fingers of the lower member locking on the bolt without transferring the load already hanging there.

In screwing the lock-nut in place, the corners of the "hex" can easily be matched up. The total height of the Drake lock-nut is said to be equal to that of a standard nut with check-nut. These lock-nuts are made in ¼ to 1-in. S. A. E. sizes, and ¼ to 2-in. U. S. S. sizes.

What Detroit Is Doing To Solve the Housing Problem

Serious Shortage of Homes Is Causing Excessive Labor Turnover—A Situation That Has Become Critical—Community Housing Corporation Organized

> **Detroit's Housing Problem**
>
> *A present shortage of 30,000 houses. Rooms and apartments almost unobtainable.*
>
> *Rents 50 per cent or more higher than a year ago.*
>
> *Labor turnover at high-water mark.*
>
> **What Is Being Done**
>
> *Community housing corporation organized.*
>
> *Many manufacturing concerns undertaking exterior building operations.*
>
> *Investigation of rent profiteering.*

SO serious has the housing situation in Detroit become that the city commission, the banks and the big industrial companies are uniting in a vigorous housing campaign. Thousands of houses must be built this summer and rent profiteering must be abolished if the manufacturing interests of the city hope to keep the workingman content with his job. The labor turnover in every plant is reaching a new high mark and is now greater than at any time in the city's industrial history. This, employment officials declare, is more directly due to the home shortage than to any other cause. Hundreds of workers, unable to find proper abode near the scene of employment, are obliged to live from 6 to 10 miles away, and it is only natural, as employment agents point out, that they quit to take jobs in factories nearer home, whenever they get the opportunity.

The Detroit Real Estate Board estimates that there is a shortage of 30,000 homes. Even the rooming houses and hotels are full. One of the larger hotels, which has been in receivership, has just petitioned to have the receivership removed inasmuch as profits during the last few months range from $10,000 to $15,000 monthly. Hundreds of men are spending all of their spare time looking for houses or flats without result. Rents on single rooms run from $4 to $10 a week. It is almost impossible to get a furnished three or four-room apartment for less than from $12 to $15 weekly, while unfurnished homes and apartments range from $50 a month up. It is estimated that these prices are nearly 50 per cent higher than two years ago.

In direct contrast are conditions at Windsor. While the Canadian city is also suffering from a home shortage, rooms are renting at $2.50 and $3, apartments at from $5 to $10 weekly, while homes and flats are going at from $30 to $35.

It is this situation that is causing Detroit to act to secure immediate relief. While the housing problem is a serious one in every manufacturing center in Michigan and Ohio, in Detroit it has already become critical. Detroit proposes to organize the Community Housing Corporation to finance the construction of 10,000 homes at once. General Motors Corporation will build approximately 2000 dwellings, while Henry Ford is continuing his house-building campaign, both at Highland Park and at Dearborn, on a greatly increased scale. The Gemmer Manufacturing Co., the American Blower Co., the Canadian Bridge Co., D. M. Ferry Seed Co. and the General Necessities Co. are but a few of many companies which propose to build at once.

Mayor James Couzens, former partner of Henry Ford, urges that the Community Housing Corporation conduct its building work on a great enough scale to cover the entire shortage this year. A committee has been appointed to formulate preliminary plans. A. A. Templeton, president of the Board of Commerce, is chairman of this committee. No decision has been reached on its proposed capitalization, but this will be between $10,000,000 and $30,000,000. This capital stock will be absorbed by the large employers of labor. By this arrangement Detroit hopes to centralize its building activities. It is pointed out that the success of the plan hinges on the willingness of large employers to take their profits, not from the actual construction of homes but from the benefits accruing from more contented workmen in homes of their own. The business will be conducted upon a margin of profit just sufficient to furnish a safe surplus.

If the corporation undertakes the construction of only 10,000 homes, an expenditure of at least $30,000,000 faces the proposed organization. It is argued that a $1,000,000 corporation, or even one with a capital of $5,000,000 or $10,000,000 without some rotating plan based on marketing of mortgages, land contracts or securities representing it, would soon have its entire capital tied up in construction.

For this reason a second organization, the Community Housing Mortgage Corporation, will be formed with a capital stock of $1,000,000 to engage in buying, selling and otherwise dealing in mortgages and land contracts and other securities arising directly and indirectly from the activities of the Community Housing Corporation. These activities would include dealing in securities, which, not being exclusively the product of the housing corporation, could not be legally handled by that corporation under existing Michigan laws.

The management of the corporation will be placed in the hands of a commission of 15 members, which will select the officers. The new organization will be patterned somewhat along the lines of the Bankers Commer-

cial Securities Corporation, New York City, and the Continental Guaranty Co. of New York and Chicago, both organized by large banking interests in those cities. They have sold more than $60,000,000 worth of collateral trust debentures.

An Investigation of Rent Profiteering

In the meantime, while these two corporations are being organized to bring the city housing relief, Mayor Couzens is conducting an investigation into exorbitant rentals in Detroit. He has a committee at work and a great deal of data is being collected. He is also going deeply into the legal phase of the affair and is threatening criminal action in certain cases.

There was practically no building work to speak of during the war period. Since the armistice and up to the present time, building operations were greatly curtailed because of the high prices of lumber, steel and other contracting and plumbing supplies. It has just been within the last two months that construction work of all kinds began in earnest. Detroit is just one year behind and nearly every other city in the country is in the same fix.

Industrial conditions here are nearly normal now. There is a demand for nearly everything manufactured in this city and the demand is going to keep the concerns pushed to the production limit for months to come. There is now a shortage of labor. Some companies are already advertising for men in other cities. If the manufacturing situation continues, it will be necessary for the Board of Commerce to conduct an extensive advertising campaign to bring labor to Detroit, and with labor urgently needed, Detroit is facing the extended problem of housing these additional men. There is plenty of work in Detroit but there are no houses and the warm days are going to cause hundreds of tents and temporary abodes to spring up in all the manufacturing districts of the city.

Banking Interests to Assist

The banking interests are now awakening to the true situation. They are relaxing from their "safety first" policy which practically barred a workingman from securing money to build a home. Before the war it was possible for a trustworthy man to go to a bank and receive financial aid. Until a few weeks ago this practice was greatly curtailed. Uncertain business conditions, the unsettled affairs of the peace conference and the high cost of materials, etc., caused the banks to become more cautious than usual and the worker who sought an initial payment for a home was usually asked to wait until mid-summer.

Even the contractors had a hard time getting financial aid. In many sections of the city one will find excavations complete and foundations finished for new homes. Work, however, has apparently been suspended for several months. Investigation usually reveals the fact that the contractor had accepted an initial payment from the prospective owner and started the work, hoping to secure the rest from the bank. When more cash was required, the contractor found that his bank was opposed to financing the project under existing conditions. Thus work stopped until such a time as the money would be available.

There is no question but what the home shortage is hitting industry hard. Men are leaving Detroit in large numbers because there is no place here for their families. Every employment agent in Detroit is thoroughly alive to the situation and the co-operation of the big industries in the proposed municipal housing project is genuine.

What the Gemmer Co. Has Done

The Gemmer Manufacturing Co., maker of automotive parts, is one of the most progressive firms in handling the housing situation. This company, employing 500 men, determined upon the policy of every employee owning his own home, nearly one year ago. It has been pushing the project and aiding its men in every way since. Its method of doing this is being used as a model for other companies.

This company has no set building fund. It merely arranges with its bank to provide Gemmer workingmen with the necessary capital and the company itself guarantees the bank sufficient security to cover the loan. This progressive policy has not cost the company a cent. The company will even go so far as to get the cash for the employee when his personal efforts in this direction might fail. The company works its building program through the Society of Savings, the organization of the Board of Commerce and through the Detroit Real Estate Board. Practically every married man in the Gemmer company's employ owns or is contemplating owning his own home.

At Lansing, Flint, Pontiac and Saginaw conditions are also very bad. The General Motors Corporation is greatly relieving the situation in these cities by its housing program, which calls for the building of hundreds of homes in each place. Akron, O., the rubber center of the nation, has a great home shortage. The situation here is almost as critical as in Detroit. Hundreds of men are walking the streets and sleeping wherever they get a chance. Even single rooms are at a premium. The city has brought 700 contractors in from Philadelphia and a huge building project is under way. It is estimated that at least $10,000,000 worth of new buildings will be required in Akron alone.

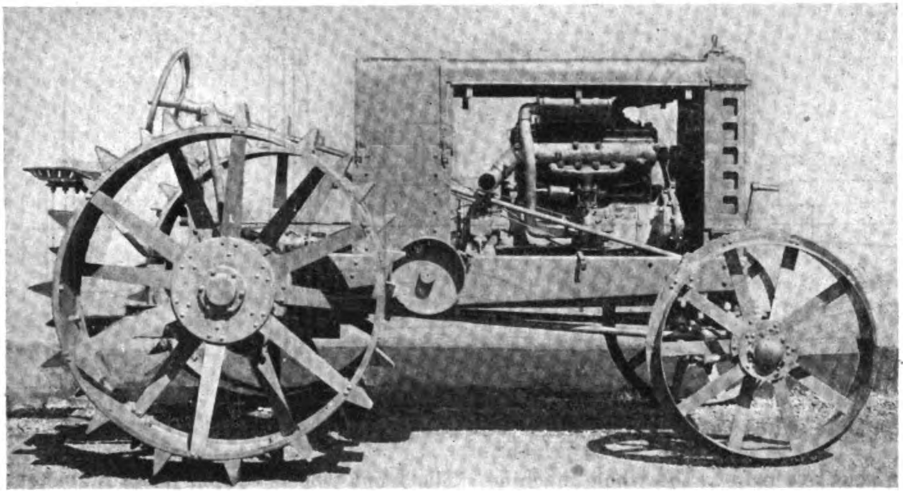
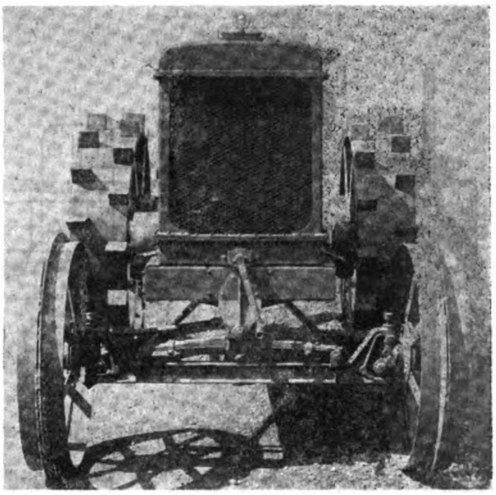
Champion Tractor an Assembled Product

Components Comprise a Buda Engine, Fuller Transmission and Chicago Rear System—Designed with a View to Elimination of Unnecessary Weight and Ready Accessibility of Parts





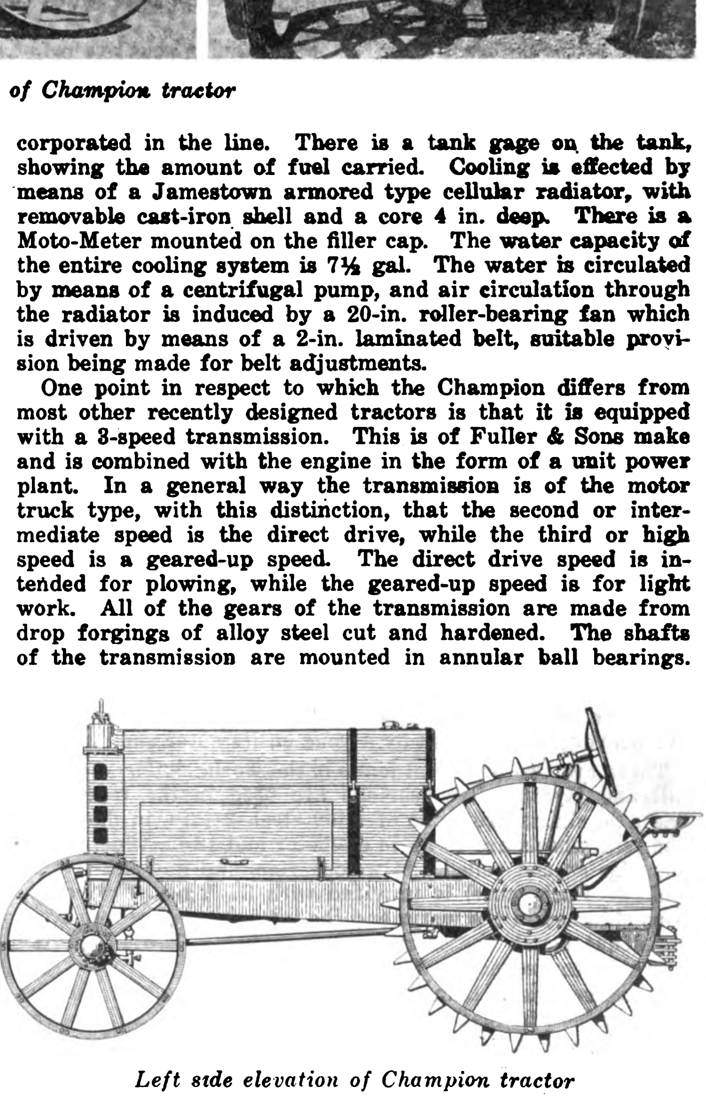
Side and front views of Champion tractor

THAT it is now possible to assemble a farm tractor complete from parts offered in the market is proved by the example of the Champion tractor, which made its debut on the market at the Kansas City tractor show. This machine is the product of the Champion Tractor Co., Argo, Ill., and is manufactured from designs by Reed & Glaser, Indianapolis. Elimination of surplus weight and the possibility of removing any unit without disturbing adjacent ones have been some of the main objects aimed at by the designers. Practically all of the units are manufactured by firms which have established a name for themselves in related industries. All shafts are mounted on ball or roller bearings, and the bearings used are said to be of very liberal size for the loads they have to carry. All of the wearing parts are completely enclosed, and the tractor as a whole is of simple and clean-line design. It is quite light in proportion to the power it is capable of delivering on the drawbar.

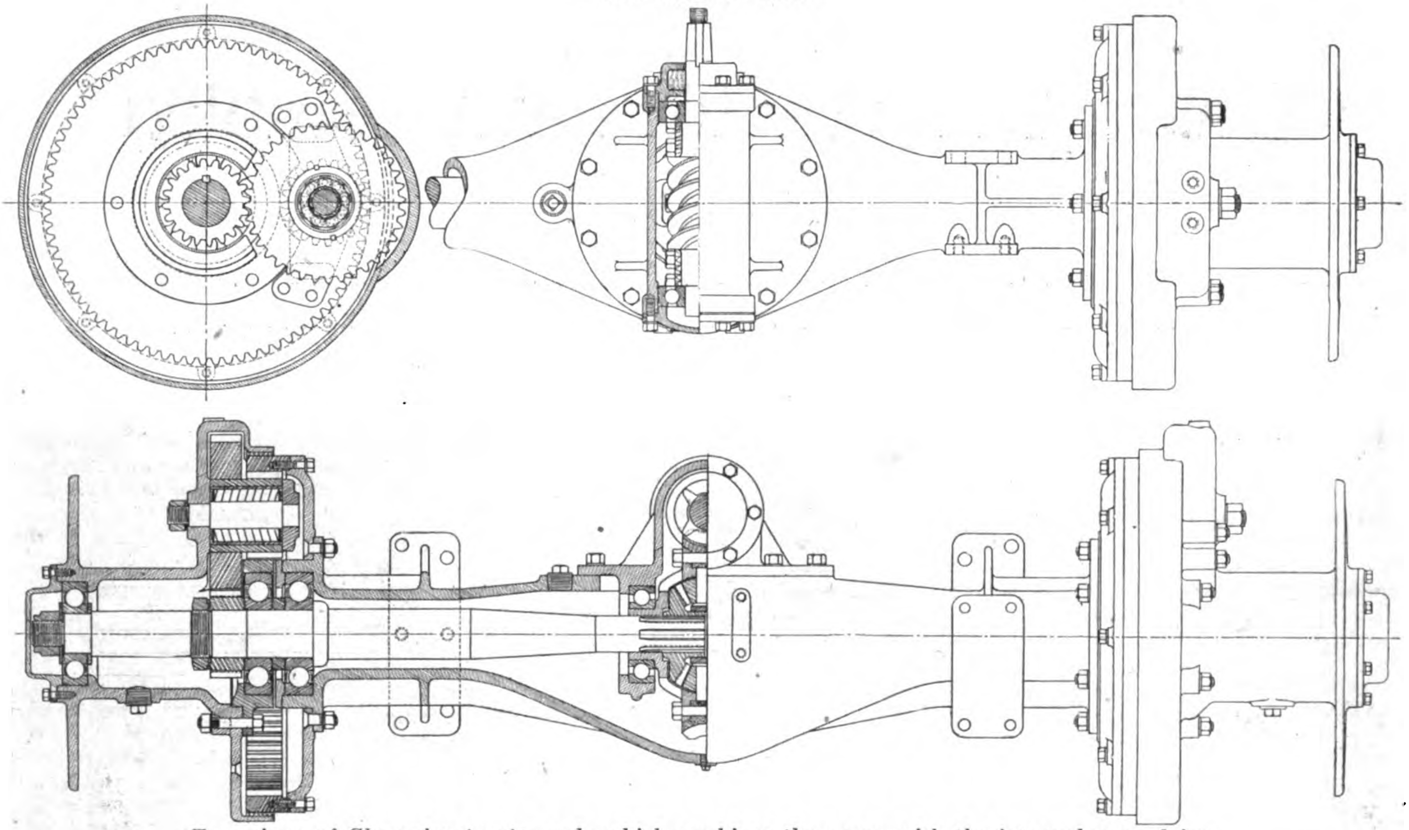
A Buda 4-cylinder special tractor type of engine is fitted, with a bore and stroke of 4¼ x 5½ in. respectively. It is unnecessary to go into the details of construction of this engine, as a full description has appeared in a former issue of AUTOMOTIVE INDUSTRIES. Suffice it to say that the engine is provided with a Pierce automatic governor which maintains a constant speed of 1000 r.p.m.; it delivers from 29 to 32 hp. on the belt, while the drawbar horsepower attains a maximum value of 17½, and a constant value of 14 can be depended upon. There is full force feed lubrication to all engine bearings, from a gear type pump which produces a pressure of 30 lb. The total weight of the engine, including the regular equipment, is 800 lb.

The tractor exhibited at Kansas City was designed to burn gasoline, though the Buda tractor engine will also handle kerosene. A Carter vertical 1¼-in. carbureter, U. S. A. type, is fitted and connects with the gasoline tank of 26½ gal. capacity. The fuel tank is located back of the engine space and is of such form as to continue the outline of the bonnet. All air drawn into the carbureter is passed through a dry type enclosed air cleaner. Fuel is fed from the fuel tank to the carbureter by gravity, a fuel strainer being incorporated in the line. There is a tank gage on the tank, showing the amount of fuel carried. Cooling is effected by means of a Jamestown armored type cellular radiator, with removable cast-iron shell and a core 4 in. deep. There is a Moto-Meter mounted on the filler cap. The water capacity of the entire cooling system is 7½ gal. The water is circulated by means of a centrifugal pump, and air circulation through the radiator is induced by a 20-in. roller-bearing fan which is driven by means of a 2-in. laminated belt, suitable provision being made for belt adjustments.

One point in respect to which the Champion differs from most other recently designed tractors is that it is equipped with a 3-speed transmission. This is of Fuller & Sons make and is combined with the engine in the form of a unit power plant. In a general way the transmission is of the motor truck type, with this distinction, that the second or intermediate speed is the direct drive, while the third or high speed is a geared-up speed. The direct drive speed is intended for plowing, while the geared-up speed is for light work. All of the gears of the transmission are made from drop forgings of alloy steel cut and hardened. The shafts of the transmission are mounted in annular ball bearings.



Left side elevation of Champion tractor



Two views of Champion tractor axle which combines the worm with the internal gear drive

Control of the different speeds is on the sliding selective principle, through a ball-handled vertical lever convenient to the driver. The clutch is of the dry disc type, 11 in. in diameter and is entirely enclosed. It is controlled by the usual foot lever and is normally in engagement. From the transmission the belt drive is taken off. The belt pulley is 12 in. in diameter, with 6 in. face, and the belt speed is 2600 ft. at 850 r.p.m. of the engine. The pulley is located on the right-hand side of the tractor.

It is in regard to the final drive and the rear axle construction that the Champion tractor differs from most others now on the market. There is a double reduction of speed, the first reduction being through a worm and wheel and the final reduction through a spur gear mechanism. A live rear axle is used, and all of the driving gears are completely enclosed. The number of reductions is four when driving on the high gear, three on the plowing speed, four on low and four on the reverse. The reduction ratios are as follows: High, 33.76:1; second, 57:1; low, 97.58:1; reverse, 154.98:1. From the sectional views herewith the arrangement of the final drive can be clearly seen. The axle shaft carries a spur pinion at the inner side of the wheel hub. This pinion meshes with the larger one of two adjacent spur gears mounted on a stud secured into the inner hub flange of the driving wheel. The smaller one of the spur gears rolls on a stationary internal gear carried by a circular plate bolted to a flange on the axle housing. The two planetary spur gears are mounted on a Hyatt bearing and the stud carrying this bearing is supported by a yoke on its outer end.

There are two universal joints in the worm shaft. Annular ball and Hyatt roller bearings are used in the rear axle. The axle shafts are made of alloy steel, 2½ in. in diameter. The rear wheels are 48 in. in diameter and 12 in. wide. They comprise special rolled and welded rims and flat, hot-riveted spokes. Each wheel is provided with 30 lugs. The reductions obtained in the worm and the internal gear respectively are about equal, the worm reduction being 7.75:1 and the internal gear reduction 7.5:1.

A pressed steel channel section frame is used, the channel side members increasing in depth from the front to the rear and fastening at the rear end to lugs on the rear axle housing. The use of this frame permits of removing the transmission and the engine bodily from the tractor without dismantling the whole machine. The front wheels are 32 in. in diameter by 6 in. width of rim and are also of the built-up type. Steering is effected by means of a large hand wheel through a Wohlrab worm and nut irreversible mechanism.

The wheel base of the Champion tractor is 80½ in. and its tread at the rear is 58 in. The total width is 70 in. and the total length 130 in. The front axle, which is of I section design, is braced to the frame by two long radius rods which have a ball joint at the forward end of the transmission casing. The frame is supported upon the front axle through the intermediary of a semi-elliptic spring, which is provided with oblong eyes at both ends so as to provide for the necessary spring play without the use of shackles.

The drawbar hitch is adjustable both laterally and up and down. To the rear end of the platform is secured a bracket with a number of rearwardly extending superposed lugs, between any two of which a transverse bar can be placed. Concentric holes are drilled through all of the lugs, and a pin can be inserted to hold the crossbar in place. This crossbar is drilled with a number of holes along its length which provide for lateral adjustment of the hitch.

The total weight of the Champion tractor is 3190 lb. It is designed to handle three 14-in. plows and a 24-in. thresher.

Roberts Priming Cock

THE Roberts Brass Mfg. Co. has brought out a dustproof priming cock which is very similar to other priming cocks except that the handle, which is a stamping, has a small circular cover plate integral with it. This is twisted over so as to cover the top of the priming cup when the cock is closed. This prevents the settling of dust in the cup and is sold for use with automobiles, motorcycles, trucks, tractors, motor boats, etc.

Fuel Limitations of Tractor Engines*

Methods of Overcoming Common Tractor Engine Troubles Pointed Out in Review of Design

By H. L. Horning

Chief Engineer, Waukesha Motor Co.

FOUR-CYLINDER tractor engines seem to be rapidly becoming standard. There is a slight increase in the use of overhead valves, but the L-head cylinder is the most popular. Ford, Overland, Maxwell, Studebaker, and Dodge cars are greatly in the majority on farms, and farmers are familiar with this type of engine. Tractors are not built for nor operated by engineers, and many elements of design in a tractor for use in the next five years must be determined from an economic viewpoint. Besides, it can be shown that with the knowledge we now have a very close, if not equal, result in power and economy can be obtained with an L-head as with a valve-in-the-head engine for truck and tractor use, within the limits of 90 lb. m.e.p. and 0.62 lb. fuel consumption per horsepower-hour at speeds within 10,000 r.p.m.

Tractor Forms—Tractors vary considerably in form and design. There are four general types of tractors:

A—Automobile type, of which Ford, G.M.C., Heider, R. & P. are representative.

B—Cross engine type, of which the Huber, Parrett and Case are representative.

C—Special purpose type, of which Holt, Best, Cleveland, Trundaar, Yuba, Bullock are types of the Caterpillar forms, while the La Crosse and Bates Mule, together with other unique forms, particularly designed for certain service form the others of this class.

D—Farmer type, such as Gray and Nilson, many of the International, Avery, E. B. models are built on the basis of long field experience, and give general satisfaction.

Engine—Four-cylinder, vertical, L head.

Transmission—Four speeds, three forward and one reverse.

Method of Propulsion and number of wheels—Four wheels.

Service Problems with Relation to Fuel

It is unnecessary to go into engine design, as there are many engines giving fair success. It has been thought advisable to deal at length with the list of troubles with engines which have been found to demand the greatest amount of attention from the farmer.

The list below is taken from an investigation by the Department of Agriculture, covering 2179 reports.

TRACTOR-ENGINE TROUBLES

Magnetos	299
Spark plugs	110
Carbureters	104
Bearings	80
Cylinders and piston rings	61
Valves and springs	43
Lubrication	29
Starting	28

We will now proceed to consider each of the foregoing from a broad standpoint, and to particularly point out the relation of fuel to these difficulties.

Magnetos—There is no doubt that magnetos are liable to troubles which are due to the conditions of tractor service in which this beautifully made device is expected to stand out all winter or through April showers and function immediately on demand of the careless owner. With present fuels it is difficult to ignite the mixture, owing to defects in carburetion. A number of tests show that with present systems of carburetion as much as 20 per cent of the fuel fails to contribute to the power output. This loss affects the results through rapid coating of spark plugs with the carbon of incomplete combustion. Magnetos do not benefit any more than the motors generally from carbon coating and short circuit of the plug. Reports of service men indicate that magnetos are often blamed for conditions arising from carbon deposits in the cylinders.

Spark Plugs—Closely related to magneto difficulties are those in which the spark plug is involved. When we are told that upward of 100,000,000 spark plugs are sold annually, we realize the difficulties which present engine construction and the necessity of using low grade fuels impose upon the spark-plug manufacturer. Generally speaking, a spark plug in a tractor engine is seldom exposed to the temperature stresses of an aviation motor, and yet one of the controlling factors of power production in tractor engines is the preignition of the mixture due to high spark plug temperatures. This, of course, applies to the electrodes which attain high temperatures. Present fuels contain heavier elements which have end points from 367 deg. Fahr. upward, and these break down easily. Good designing may eliminate preignition largely, but fuel limitations cause many of the objectionable spark plug difficulties discussed under the heading of detonation. While the tractor spark plug with poor designing of cylinders with respect to water circulation is prone to cause preignition, yet many plugs run too cool, which prevents the burning of the inevitable carbon deposits and, in fact, very much favors the formation of carbon. One of the most important points in the design in a tractor motor is the location of the spark plug. The general considerations are as follows:

Summary of Spark Plug Requirements

1. The plug should be located as near as possible to the center of gravity of the mixture in the combustion chamber when the mixture is about to fire.
2. It should be so located as to be out of the exhaust gas stream.
3. It should be so located as to get the blast of this incoming rich mixture, or in such a place as will insure that the mixture surrounding the electrodes will be highly explosive and not deadened by residual charge.
4. The cooling water stream which has picked up a large volume of heat from the exhaust valve environments usually insures temperature enough to keep a good clean plug and cooling effect that will keep preignition out of the probabilities.
5. No cylinder head should be designed which will demand a long spark plug so as to reach the mixture.
6. A vertical spark plug is the only type which runs a long time without cleaning. In a valve-in-head motor the spark plugs must be placed at an angle in the head, and this is one of the inherent defects of this motor, as the oil cannot drain as well from a plug so located as from a vertical one.
7. The plug should not be placed so as to get the direct sweep of gases passing by the piston and rings on the suction stroke.

The above observations are particularly for the guidance of the engine designer, who must also bear in mind that the motor must work irrespective of where the farmer buys his plugs. Should the user desire advice as to the type of plug, it is only necessary to observe the following points:

*Paper read before Detroit Section Society of Automotive Engineers, April meeting. Condensed.

A. The insulator should be of the best grade of porcelain or stone now available.

B. The center electrode should be at least 3/32 in. in diameter, well smoothed off, rounded, and the distance from its tip to the outside air a minimum. Cooling ribs are very desirable. No sharp corners or points should be presented to the combustion chamber.

C. It is not so easy to give general specifications for a good mica plug, although there are many good ones. As a class they are to be avoided.

Aside from temperature problems, the greatest difficulties with spark plugs arise from the deposit of carbon. Excessive lubrication in the combustion chamber may result from heavy fuel and further favors the short-circuiting of the plug with oil and carbon.

Carbureter Problems

Whatever the shortcomings of carbureters under other conditions, there is no doubt that they must stand some real maltreatment for any and all trouble symptoms on the truck and tractor. The continual fussing with carbureters in and out of adjustment is responsible for the wide range of results obtained.

The gradual increase in the boiling temperature of the heaviest fraction in the fuel is imposing a difficult problem on the engineer and is also the cause of frequent and sometimes unnecessary adjustment of carbureters. Fuels differ widely, as will be shown in a later part of this paper, running from the light, easily vaporized fuel entirely within the range of modern gasoline carbureters and vaporizers to way beyond what can be handled. As a matter of fact, it is easily demonstrated that the average engine actually returns useful power from only 80 per cent of the fuel. Whatever may be the normal losses to the radiator, exhaust, friction horsepower, radiation, etc., in a modern engine burning a perfect mixture, one-fifth of our gasoline with an end point of 450 deg. cannot be burned in our present engines. We have demonstrated that it is commercially possible to increase mileage 50 per cent in many cases where mere vaporization is substituted for metering and fixing.

The name carbureter became a misnomer when the end point of gasoline exceeded 30 deg. Fahr. Present fuel specifications call for 50 per cent of fuel to come off under 302 deg. Fahr. All over 60 per cent presents a serious problem in vaporization.

Carbureters as commonly made to-day consist of four valves, using the term valve in the broadest sense as a means of controlling flow: 1—A needle float valve for maintaining a constant level of fuel; 2—A fuel valve or valve supplying the fuel in definite quantities; 3—An air valve or passage supplying air in response to the engine demand and in most systems regulating the fuel flow; 4—A heat valve, broadly speaking for the purpose of supplying a sufficient quantity of heat to vaporize that proportion of the fuel which lies beyond the 302 deg. Fahr. point and which is not properly vaporized by common carbureter and intake passages.

Modern carbureters are either devoid of the heat valve or have only rudimentary and inadequate means of thoroughly vaporizing the fuel. Herein lies the hope of our immediate future. No firm will be successful that cannot supply adequate heat control. By far the greatest number of our engine difficulties from fuel characteristics arise out of the simple necessity of a properly vaporized fuel.

Supplying Heat to Fuel Mixture

The heat may be supplied in many ways. The valve referred to may consist of a thin membrane to conduct heat of water or exhaust. It may consist of a thick-ribbed section. It may consist of ingenious heating of the air or fuel or both, or a combination of many heat devices; but whatever it is, fuel must be vaporized and the operator must have control of the flow of heat to the fuel.

Manograph charts of common designs indicate a vast change in mixture composition from one explosion to the other. One explosion varies from another as night and day. Preignition, rapidity of initial ignition stages, variable explosion lines, detonation, multiple combustion, incipient combustion, late temperatures and pressures all alternate with good combustion effects.

One investigator has shown in working out a temperature control that a change of 8 deg. Fahr. in the neighborhood of the correct temperature (which I am not at liberty to give to you) makes a difference of 20 per cent in economy. The Bureau of Standards, working with a highly ingenious device for measuring flame propagation in the cylinders of a Liberty engine, finds that flame propagation varies from one explosion to another in the ratio of 1 to 7. Beyond these citations many practical evidences point to the fact that the fundamental defect of our present practice is lack of vaporization, hence heat control.

The foregoing remarks refer to the indefinite fuel known as gasoline. The art of vaporizing kerosene is still in an undeveloped state, and we fail in handling kerosene for the same lack of a better understanding as to how to prepare the mixture.

No mention has been made of the limitation of fuels due to chemical compounds of such instability that they will not stand the destructive effect of the heat and pressure developed in the first stages of combustion.

The explanation of considerable deposits of carbon in the cylinder and of the gas knock known as "pink" preignition, etc., generally most noticeable at the bottom of a hill, upon the sudden use of the accelerator or at overload, so called, is fuel composition. This will be dealt with under the heading of fuel, but is mentioned here as one of the limitations of fuels which can be distinctly reduced by proper vaporization methods.

Bearings and Lubrication

Nothing can take the place of design and good workmanship in bearings, nor can lubricating oil be expected to cover the defects of a bad system of lubrication.

The common method of lubrication is splash, in which the level is established by overflow dams. Another form—and the most reliable—is the splash system in which the oil level in deep troughs is maintained correct irrespective of the inclination of the engine. The oil-pump capacity in pumping the oil into the troughs is just equal to the capacity of the scoops to throw the oil out. Inasmuch as the oil pump capacity varies as the speed of the engine and the rod scoop capacity varies, the level of the oil is always assured and constant.

Force feed through hollow crankshaft is a well-known and high-class system. It has not been widely adopted because of the difficulties with leakage of oil under pressure both past the piston and rings and at the crankshaft and because of the unusual workmanship required for the pressure maintenance. In both the above-mentioned systems old oil is pumped over and over, and this leads to bearing troubles with tractor engines.

Defects of Lubricating Oil

Lubricating oil is little understood even by the refiners. Most tractor oil is so loaded with the heavier portions that under high pressure and temperature under the piston heads and walls it breaks down into lighter oils, carbon and tars. Added to this, many engines suffer from dirt, dust and sand which enter either at the carbureter or breather. Taken together, the oil in the crankcase of an engine in use for a month with either the splash or common force-feed systems is usually a bad mixture and entirely unfit for lubrication uses.

With the force-feed system unusual care must be taken to strain and settle all grit or dirt out of the oil, or it will cause unusual damage to journals and bearings. No such care is necessary with the splash system, as it seems to develop the least difficulties with dirty oils. With clean oil well filtered in use and an oil of good body, the force-feed system works exceedingly well so long as the bearings are in good adjustment. A surplus capacity of oil must be available at all times, so one or more bearings in a loose condition will not starve other bearings. Unusually good piston and cylinder fit must prevent overrolling of cylinders when rod bearings are loose.

The ideal system, if expense and care are no object, is the

force feed of fresh oil to crankshaft bearings and cylinder in exact quantities. So far as results are concerned on the surfaces, bearings lubricated by this method are not only the most economical in oil consumed but also insure the longest life to both journals and bearing surfaces.

This brings us to the effect of heavy fuel on the bearings of tractor engines. Incomplete vaporization leaves heavy fuel unburned, incompletely burned and decomposed on the walls of the cylinder and combustion chamber. Under the action of high heat the fluid residue flows down the cylinder and past the rings through the oil drain holes so commonly used into the crankcase.

The products of complete and incomplete combustion found in crankcase oil range in hydrocarbons from formaldehyde to sugars. They include acetone, alcohols, serghums, formic acid and a list of disinfectants varying in constitution according to the circumstances of combustion. This mixture, taken together with the solid contents mentioned above, constitutes about the worst lubricant a cylinder and bearings could have. The lower crankcase is the catchbasin for the byproducts of the imperfect combustion process. It is the main sewer for decomposing body fillers of our poorly compounded lubricating oils. It is the settling basin for steel, iron and bearing particles which slough off into the lubricants, and the crankcase with its oilpan forms the dustpan of the self-appointed air cleaner which duty every engine takes upon itself. Taken from an unbiased standpoint, have not engineers in tractor engines of to-day finally arrived at about the worst lubricating conditions possible? Is there any device which would permit more fuel to get into the lubricant than our present design of oil scraper pistons? The man was a great philosopher who said, "Tractor engines work in spite of the designers and users."

Effects on Journals and Bearings

The heavy fuel and byproducts of combustion seem to have bad effects on steel journals and bearing materials. In England some practical men, and engineers as well, consider an engine "done for" if it is once thoroughly saturated with some of the fuel compositions.

Economic factors impose the splash system and its most thoroughly worked out form as being a good standby under all circumstances. Most men understand it best, or, to be frank, pay least attention to it. As an all-around system it takes care of itself better than any other. The ideal system of fresh oil to all points is perfect, theoretacilly, but the complication and details, together with thickening of oil in cold weather, make it hard to introduce. The force feed through the crank will become widely used when manufacturers and users know more about it.

Bearings suffer under heavy fuel conditions due to the high pressure of detonation and preignition. Preignition can be controlled by design, as will be noted under Cylinders, Pistons and Rings. Both preignition and detonation are limiting factors of our modern fuels.

It is not possible to state which of the two evils is the most detrimental to the bearings, the dirty condition of the engine crankcase or the detonation pressure.

In closing these remarks on bearings it is well to call attention to the increase in bearing troubles with decreasing fuel quality and the increasing fuel and waste product content of lubricating oil since using the pistons with lubrication drain holes.

Cylinders, Pistons and Rings

An ideal combustion chamber would be a sphere with a uniform wall thickness, of uniform temperature as high as possible without causing decomposition of the fuel in use. Practical considerations make such a combustion chamber not attainable at present.

Heavy gasoline and kerosene and fuel made by cracking processes ranging in boiling points from 302 to 575 deg. ignite at lower temperatures than better gasoline. Under stress of temperature and pressure they detonate after the initial explosion. The preignition is lost work and is damaging to the bearing. Preignition may be the one cause of detonation.

The ideal for which we have all been striving is the burning of all fuel down to heavy kerosene and even beyond by designing all the apparatus involved so as to prevent preignition, detonation and breaking down of the fuel; this to be accomplished without water, special fuels or admixtures, with a fuel consumption approaching that with the best gasoline and with a minimum loss of mean effective pressure.

To measure progress we have set up a yardstick of performance, using the ratio of fuel consumption per horsepower-hour to the brake mean effective pressure.

In burning heavy fuels the greater the heat application the better the economy figure. The greater the heat the less the brake mean effective pressure. All devices attempt to keep horsepower output to as near the gasoline output as possible by supplying a minimum of heat to the incoming mixture. You will note that great economy usually goes with low mean effective pressure.

By thoroughly vaporizing the kerosene in the manifold, it is possible at this time to get within 10 per cent of the present gasoline horsepower; to get equal fuel economy with gasoline. Using the same principles it is possible to improve gasoline economy by more than 20 per cent.

It has long been known in the art of coal-gas making that combustible hydrocarbons formed under the high temperature conditions of the gas retort have such stability under heat that considerable heat energy is necessary to break them down or to change their atomic structure. Such fuels act with clean combustion lines. Compression pressure reaching far beyond anything used in practice to-day results in no preignition detonations and in increased horsepower outputs. Such fuels have the benzol ring as their base and range down to naphthalene and anthracene. A mixture of these with ordinary gasoline or kerosene will eliminate the knock at good compression, even when the proportions of benzol and derivations are low. In motors of poor design where knocking is common a much better horsepower can be obtained with these stable fuels.

Whether it is possible to produce fuels stabilized by the ring compounds is an economic problem which is now receiving the attention of the best business brains of this industry.

Fuels are now being produced by cracking and other processes which bid fair to meet some of the demands for better and lighter fuel.

Hot spots in the cylinder cause the greatest trouble with modern fuels. Cylinder walls, pistons and rings suffer owing to the poor vaporization of fuel. The heavier constituents of the fuel mix with the lubricating oils which pass upward, thus reducing their viscosity and lubricating value. Dirt, dust and carbon on the cylinder wall all reduce the life of the piston, ring and wall surfaces. Aside from better vaporization there is room for great improvement in piston and ring design. Piston design offers about the only chance of keeping down the combustion-chamber temperature.

Valves and Springs

Poppet valves are always a problem. Heavy fuels cause trouble at this point because of their imperfect vaporization. Most valve troubles are due to carbon deposits, warping of cylinders and improper water circulation. It would be a great aid to the maintenance of good compression and valve seating if the valve could be positively revolved. Valves are damaged because of the unequal heating of the seats and stem. Revolving the valve slightly, each revolution distributes the heat load, and eventually the valve develops an absolutely correct seat. In this connection the device must not cause any more care, cost of maintenance or annoyance than the valve grinding. Valve springs suffer indirectly because of the fuel due to gumming of stems.

It is fortunate that the Bureau of Standards is taking up a program of investigation on lubricating oil which when complete will give us the data that will be the basis of future lubrication.

Generally speaking, the characteristics of most lubricating oil offered to-day by reliable refiners are dependent more upon the convenience of the refiner than upon the requirements of the user of the oil. Lubricating oil can be considered to consist of three parts: The light spindle oil, the medium weight, and the heavy cylinder stock.

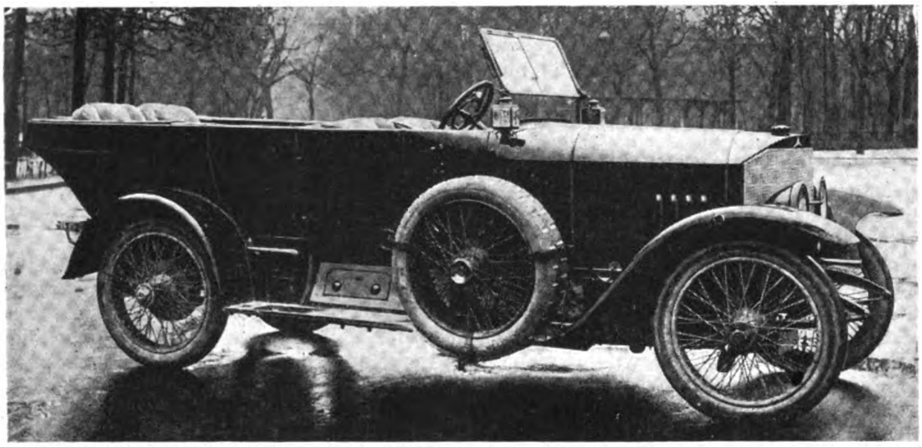
Ex-Kaiser's Latest Mercedes Car

Machine Captured by French in Strasbourg Has Knight-Type Engine, Full Electrical Equipment and a Body of Advanced Design

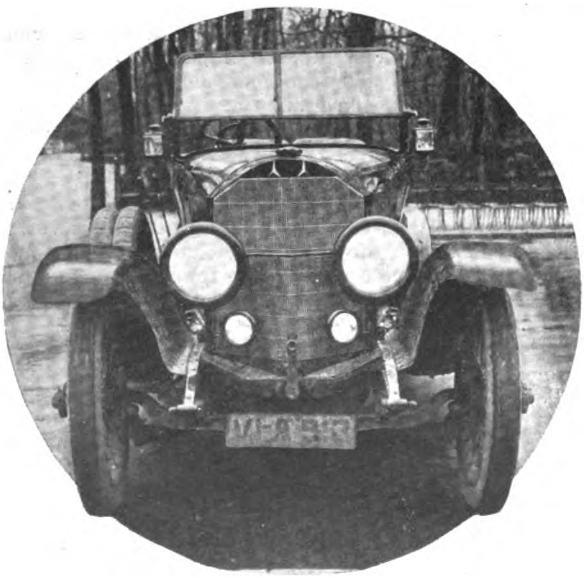


EX-KAISER WILHELM II's latest automobile appeared on the streets of Paris recently. During the summer of last year the German Emperor placed an order with the Daimler Motoren Gesellschaft at Unterturkheim for the latest type of Mercedes chassis. This was delivered to the Forrler Body Works at Strasbourg for a special touring body to be fitted, and the work was just about completed when the armistice and the flight of the Kaiser into Holland made delivery a rather difficult matter. When the Allied armies went into Strasbourg communication with the interior of Germany was cut off, and instead of being delivered at Berlin the Emperor's car was last month driven over French roads into Paris.

This latest type Daimler Mercedes is a four-cylinder car having a Knight sleeve-valve engine of 100 by 150 mm. (3.9 by 5.9 in.) bore and stroke. It is officially rated at 24-45 hp., but actually develops 70 hp. at 1800 revolutions. A Mercedes carbureter, with extra air control, is fitted, and the engine is provided with a supplementary lubricating system for the upper portion of the sleeve valves. Ignition is by high-tension Bosch magneto, placed on the left-hand or exhaust side of the engine, and driven from timing gears at the rear. The electric lighting set is also Bosch, the generator being on the right-hand forward end of the engine. The starting motor, however, is a Bijur.

The body work is a particularly fine example of up-to-date German lines. As will be seen from the illustration, the sides are narrower at the bottom than at the top, this giving an outward flare. About four inches from the top the sides become absolutely vertical, and the top rail of the body is in a straight line with the top of the hood. This, together with the straight line formed by the break from the inclined to the vertical sides, gives a very pronounced straight line effect to the body. The folding top disappears in the body, while the stern of the car is of the reversed clipper bow type, giving the greatest length near the top of the body. Seats are of the Pullman type, with two very comfortable folding seats facing forward. The windshield is divided vertically down the center, so that the driver's portion of the shield can be opened while the passenger obtains full protection. Glass is fitted in place of the usual board between the bottom of the windshield and the dash. Fenders are only moderately domed, those at the front being a single piece with the valences, and no bolts being visible. The car is fitted with detachable wire wheels, with two spares carried on the right-hand running board. The headlights are carried in the normal position in front of the radiator. The small lamps are rather peculiarly placed below the headlights but nearer the center of the pointed radiator than are these two latter. In addition to these there are two square carriage lamps carried on brackets attached to the windshield supports.

ACCORDING to an article in *Der Motorwagen*, an oil pump has been patented by a Munich inventor which consists essentially of two six-step rotating pistons and connections. The first piston acts as the oil suction, and the second as the pressure delivery.



The ex-Kaiser's Mercedes car brought to Paris

A Plan to Stabilize the Dollar in Purchasing Power*

The Effect of Our Present Monetary Standards on Prices—A Suggestion That We Vary the Value of the Dollar and Thus Fix Its Buying Ability

By Irving Fisher

OBVIOUSLY no explanation of a general rise of prices is sufficient which merely explains one price in terms of another price. To say that the cause of rising "prices" is rising "wages" is merely to say that the prices of commodities have risen because the price of labor has risen; and we might as well turn it about and say that the price of labor has risen because the price of food has risen and so driven workmen to strike for higher wages.

Scarcity will, in selected cases, go far toward explaining the rise of individual prices. But it will not go far toward explaining changes in the general level of prices—at least not before the beginning of the great war and only partly since that time.

All those who have offered explanations make one fatal mistake. They look at the wrong side of the market. They seek the causes wholly in the goods, the prices of which have changed, and not at all in the money, in terms of which those prices are expressed. It is hardly probable that commodities should rise in price en masse without some simple explanation in common. This corresponds with common sense.

Price Fluctuations Due to Money Conditions

Our conclusion is that until recently, at least, it was a fall in the value of gold, or money, that had taken place, rather than a simultaneous rise in the value of everything else.

That great price movements are chiefly monetary is evidenced by the fact that countries of like monetary standards have like price movements. Thus—to consider gold-standard countries—there is a remarkable family resemblance between the curves representing the index numbers of the United States and England. Again, the price movements in silver countries show a strong likeness, as in India and China from 1873 to 1893. On the other hand, we find also a great contrast between gold and silver countries. Speaking roughly, we may say that between 1873 and 1896 the price level in gold countries fell 25 per cent and in silver countries rose 30 per cent.

In the present war the data are so meager that it is impossible to express the relations in exact figures, but we may arrange the different countries in the approximate order in which their prices have risen. As a result we find that the order of the nations corresponds, in general, with the order in which the currency in those nations has been inflated by paper as well as with the order in which their monetary units have depreciated in the foreign exchange markets. This order—of ascending prices and of inflated currency—is: India, Australia, New Zealand, United States, Canada, Japan, Sweden, Switzerland, Denmark, Italy, Holland, England, Norway, France, Germany, Austria and Russia. Confirmatory evidence is found in the fact that the ups and downs of prices correspond with the ups and downs of the money supply. Throughout all history this has been so.

The present war furnishes important examples of this. In the United States the curve for the quantity of money in circulation and the curve for the index number of prices run continuously parallel, the price curve following the money curve after a lag of one to three months, as might be expected, money being the cause and price the effect. It was in August, 1915, that the quantity of money in the United States began its rapid increase. One month later prices began to shoot upward, keeping almost exact pace with the quantity of money. In February, 1916, money suddenly stopped increasing, and two and a half months later prices stopped likewise.

The conclusion toward which the foregoing and other arguments lead is that in the past the great outstanding disturber of the price level has always been money, and that at present the great outstanding cause of the high cost of living is money. It is curious that every time inflation of any kind has visited a country the public has had to be re-educated. The evils of colonial and continental paper money were forgotten by the generation of the Civil War, and the evils of the greenbacks are forgotten by most people to-day. At the present time we are confronted with still another kind of inflation, due not to specie, but to the use of checks. In so far as we subscribe to our war loans out of money borrowed at the bank—that is, out of an increase of deposit currency and not out of real savings—we are adding to inflation and to its evil effect on the cost of living.

Money is so much an accepted convenience in practice that it has become a great stumbling block in theory. Since we talk always in terms of money and live in a money atmosphere, as it were, we become as unconscious of it as we do of the air we breathe. Some people, even intelligent people, bolster up the illusion that the dollar is a stable standard of value by reference to the fact that "the price of gold" never changes. Only recently a former Government officer asserted that the value of gold is evidently constant because its price is fixed!

A dollar is 25.8 grains of standard gold—that is, of gold nine-tenths fine; and, since an ounce is 480 grains, the number of dollars in an ounce is $480 \div 25.8$, or 18.60. In other words, any 100-ounce lump of standard gold taken by a gold miner to the mint can be cut up and coined into 1860 dollars and handed back to him. Naturally he gets $18.60 an ounce, and this "price" can never vary so long as the weight of the dollar does not vary.

Gold Dollar Fixed in Weight but Not in Buying Power

Thus 100 ounces of gold will always be worth 1860 dollars of gold so long as 1860 dollars contain 100 ounces of gold; just as a quart of milk will always be worth two pints of milk so long as two pints make a quart. Gold is stable in terms of itself and in terms of itself only. Fixing the dollar at 25.8 grains of gold fixes the price of gold at $18.60 an ounce. But, of course, this fixity of dollar weight, or of gold price in terms of gold, does not fix its price or value in terms of other commodities. It does not release gold from the effects of supply and demand. The value of the dollar, as shown by its general purchasing power, is not stable but fluctuates with supply and demand as does the value (or purchasing power) of anything else.

If, instead of gold, we were to make milk the standard, or eggs—that is, if we used these to purchase all other things—they would acquire the same fixity of price—that is, price in terms of milk or eggs; and we would fall victims to the same illusion of inherent fixity.

An increase of money, then, always tends to raise prices. It was thus that prices rose in the mining camps of California a half dozen decades ago and in Colorado and the Klondike one or two decades ago. This local rise of prices soon communicated itself to other places; for the price level cannot

*Abstract of a paper read by Prof. Fisher before the Editorial Conference of the Business Publishers' Association.

in one locality greatly exceed that in a neighboring locality without causing an export of money to the locality of the lower level. Thus new money gradually finds its way into circulation throughout the world, raising prices as it flows from place to place, the process consisting, in all cases, of the effort on the part of somebody to get rid of an inconvenient surplus—a surplus which cannot be dissipated by transferring it from hand to hand, but only by a rise of prices. Of course, the price level is affected not only by the quantity of money. It is affected also by credit currency—that is, the so-called "money I have in the bank," which one pays out in checks. Moreover, the price level is affected by the rapidity of circulation both of money and of deposit currency and by the amount of commodities in trade. The price level may rise because of an increase of money or of deposit currency, or because of their rapidity of circulation, or because of a decrease in the volume of trade. And back of these causes (money, deposits, their velocities, and trade) lie innumerable other causes acting through one or more of them.

Dollar a Unit of Weight

Our dollar is now simply a fixed weight of gold—a unit of weight, masquerading as a unit of value. A twentieth of an ounce of gold is no more truly a unit of value or general purchasing power than a pound of sugar or a dozen eggs. It is almost as absurd to define a unit of value, or general purchasing power, in terms of weight as to define a unit of length in terms of weight. We would scarcely define a yardstick as any stick which weighs an ounce.

What good does it do us to be assured that our dollar *weighs* just as much as ever? Does this fact help us in the least to bear the high cost of living? We complain of the dollar, and justly, that it will not go as far as it used to. We want a dollar which will always buy the same aggregate quantity of bread, butter, beef, bacon, beans, sugar, clothing, fuel, and the other essential things that we spend it for. What is needed is to stabilize or standardize the dollar just as we have already standardized the yardstick, the pound weight, the bushel basket, the pint cup, the horsepower, the volt, and, indeed, all the units of commerce except the dollar.

Except the dollar, none of the old rough and ready units are any longer considered good enough for modern business. The dollar is the only survival of those primitive crudities. Imagine the modern American business man tolerating a yard defined as the girth of the President of the United States! Suppose contracts in yards of cloth to be now fulfilled which had been made in Mr. Taft's administration!

And yet the shrinkage in such a yardstick would be no greater than the shrinkage we have suffered in the far more important yardstick of commerce, the dollar; and this yardstick is used, not only in the few contracts in which the yardstick of length is named, but in all contracts of business! We tolerate our crazy dollar only because the havoc it plays is laid to other agencies.

Any Single Commodity Is Too Variable a Standard

A true standard of value, or general purchasing power over commodities, should not be dependent on one commodity merely, whether that commodity be gold or silver or wheat or what not.

Two commodities would be better than one, just as two tipsy men walk more steadily arm in arm than separately. Whenever they tend to lurch in opposite directions they neutralize each other. This is the argument which used to be urged for bimetallism, symmetallism, and other plans for uniting gold and silver. And the argument applies whenever gold and silver move in opposite directions, as from 1873 to 1896. A composite of gold, silver, copper, platinum, and all the other metals would be somewhat more stable than an amalgam of two. Money to-day has two great functions. It is a medium of exchange and it is a standard of value. Gold was chosen because it was a good medium, not because it was a good standard.

The argument that gold became money because it was thought to be a good standard of value is, so far as I can find out, an unfounded myth. Indeed, when it came into use as money, there were no index numbers and there was therefore no way of testing its stability or instability; and finally at that time there was not much need and not much thought of a standard of value, for the good and sufficient reason that there were few if any time contracts, such as promissory notes, mortgages or bonds. Almost all bargains were struck and settled on the spot. When a man was about to make a cash purchase it was immaterial to him what the monetary unit was.

But to-day if a man buys an article and promises to pay for it in three months the case is different. When the time for payment arrives it is very important for him to know whether the "dollar" is the same as was contemplated when the agreement was made. With our network of long-time contracts, running months, years, generations, or even centuries, including hundreds of billions of dollars in promises to pay money—promissory notes, mortgages, debentures, railway bonds, Government bonds, leases, etc.—the function of a standard of value—that is, a standard of deferred payments—has grown to be perhaps the more important of the two functions of money.

We now have a gold standard that is forever fluctuating. It is a gold standard with the "standard" left out! The proposal here made is really to put the standard into the gold standard—to standardize the dollar.

Vary the Weight of the Dollar

The method of rectifying the gold standard consists in suitably varying the weight of the gold dollar. The gold dollar is now fixed in weight and therefore variable in purchasing power. What we need is a gold dollar fixed in purchasing power and therefore variable in weight. I do not think that any sane man, whether or not he accepts the theory of money which I accept, will deny that the weight of gold in a dollar has a great deal to do with its purchasing power. More gold will buy more goods. Therefore more gold than 25.8 grains will buy more goods than 25.8 grains will buy. If to-day the dollar, instead of being 25.8 grains, or about one-twentieth of an ounce, of gold, were an ounce or a pound or a ton of gold, it would surely buy more than it does now, which is the same thing as saying that the price level would be lower than it is now.

But how, it will be asked, is it possible in practice, to change the weight of the gold dollar? The feat is certainly not impossible, for it has often been accomplished. We ourselves have changed the weight of our gold dollar twice—once in 1834, when the gold in the dollar was reduced 7 per cent, and again in 1837, when it was increased one-tenth of 1 per cent. If we can change it once or twice a century, we can change it once or twice a month!

Use Paper for Currency and Abolish Gold Coins

And if we use paper representatives of gold exclusively, instead of some paper and some gold coins, these monthly changes in the weight of the gold dollar can be made even more easily than the occasional changes were made which history records. In actual fact, gold now circulates almost entirely through "yellowbacks," or gold certificates. The gold itself, often not in the form of coins at all but of "bar gold," lies in the Government vaults.

If gold thus circulated only in the form of paper representatives it would evidently be possible to vary at will the weight of the gold dollar without any such annoyance or complication as would arise from the existence of coins. The Government would simply vary the quantity of gold bullion which it would exchange for a paper dollar—the quantity it would give or take at a given time. As readily as a grocer can vary the amount of sugar he will give for a dollar, the Government could vary the amount of gold it would give or take for a dollar. To-day the Government will give 25.8 grains of gold bullion to the jeweler or exporter for each dollar of certificates he pays in; next month it might give 26 grains or only 24 grains. These respective increases or decreases would of course be made for the purpose of compensating the decreases or increases in the purchasing power of the dollar.

But, it will now be asked, what criterion is to guide the Government in making these changes in the dollar's weight? Am I proposing that some Government official should be

Dayton Starting and Lighting System

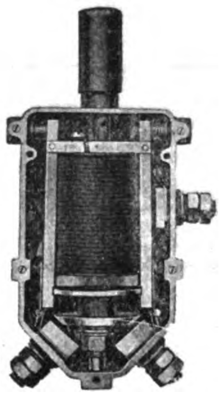
Specially Designed for Ford Cars—A Single Unit Connected Directly to the Crankshaft—Has a Special Form of Armature with Copper Bar, Form Winding Electrically Welded to the Commutator Bars

SEVERAL novel features are embodied in a starting and lighting system which is being manufactured by the Dayton Electrical Manufacturing Co., Dayton, Ohio, from designs of Vincent G. Apple. The outfit, which is of the single unit type, is specially designed for Ford cars, and it is possible to connect it directly to the crankshaft because of the new type of armature used. There is no cotton insulated wire used in its construction, the windings being made with flat copper strips cut to length and formed into hairpin loops which are inserted through a core of laminated iron discs. They are then bent into shape by a special machine to make them uniform, leaving the flat ends to weld to the commutator segments. This is done with an electric welder, which makes the commutator a part of the winding. The commutator, as will be seen from the illustration, is of the internal type. The idea of electrically welding the armature conductors to the commutator bars appeals, as it removes the weak link of the soldered joint, but it would seem to render more difficult the problem of "refilling" the commutator when worn out.

After the armature is assembled, it is impregnated with bakelite and baked, which makes it a solid, homogeneous mass impervious to oil and water. This armature, we are informed, can be shaped to fit the frame of any low-voltage dynamo.

The field frame of the dynamotor is made of semi-steel and has twelve field poles in which the armature rotates to generate the electric current. The armature winding is of the parallel type and there are twelve brushes bearing on the commutator. Two of these brushes are almost pure graphite, for lubricating the commutator, thereby eliminating any necessity of using oil on the commutator. The other ten brushes are made of metal-graphite composition.

The starting switch and automatic cut-out are combined, and this unit is claimed to contain fewer parts than any starting switch and cut-out on the market. It is mounted on the frame of the car under the heel board and is operated by pushing down on the starter button with the heel. This operation connects the battery in series, giving 12 volts for starting. When the starter button is released, it automatically comes back to the running position and the dynamotor then generates the electric current to recharge the 6-volt battery. This replaces the current which was used by the motor for cranking the engine and lighting the lamps. When the voltage of the dynamo drops below the charging rate, the cut-out in the switch automatically breaks the circuit between the dynamo and battery, so that the battery will not discharge when the car is running at too low a speed or when the engine is at rest.



Interior view, combined starting switch and automatic cut-out

Hairpins inserted through armature laminations

Antimony in Copper

THE opinion has gained ground of late that small percentages of antimony do not deteriorate copper, as used to be feared, but make it harder and leave it fit for rolling. Reviewing the recent researches on the problem in *Metall und Erz*, W. Stahl concludes that 0.3 per cent or 0.4 per cent of antimony is not at all objectionable, if present as metal or as copper antimoniate. A total impurity of the same amount of both nickel and antimony, i. e., about 0.15 per cent of each of these metals, is likewise to be welcomed rather than to be deprecated; such copper is also sound when hot. Combined with high nickel percentages, however, even a little antimony is bad; what is said for nickel also holds for manganese. When the copper contains bismuth, up to 0.05 per cent, enough antimony should be added to the fused copper at the commencement of the oxidation period to transform all the bismuth into antimoniate; the copper may then be rolled. As regards lead, similar restrictions apply.

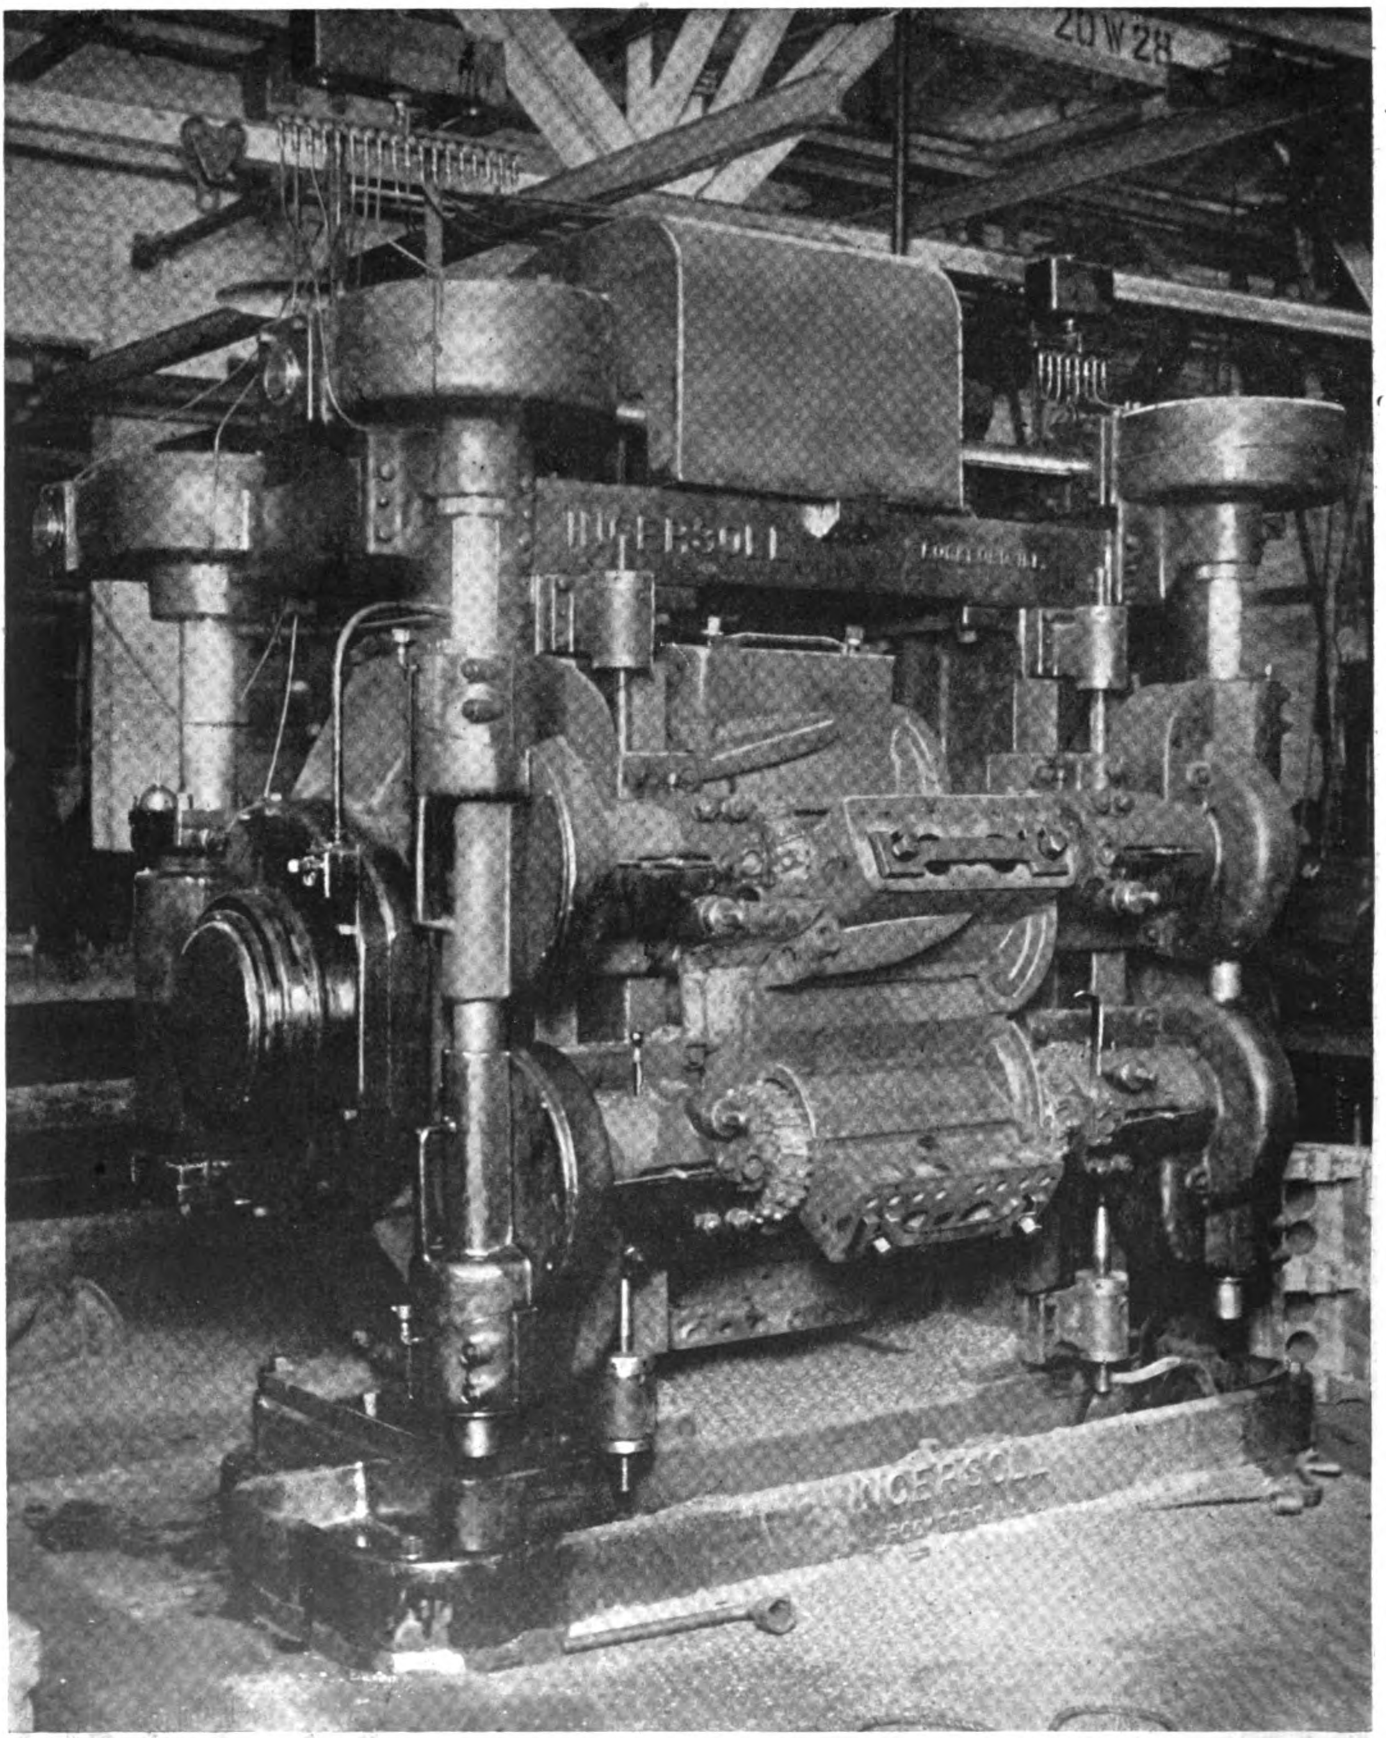
Commutator brush assembly



Milling Six Cylinder Blocks in One Operation

Rotary miller made by the Ingersoll Co. of Rockford, Ill., which handles six Fordson engine blocks at one time, milling the ends. This rotary miller takes both a roughing and a finishing cut, having four milling cutters, two on each end. It takes 3 min. to finish a cylinder block on this machine

Handling Parts in the Shop
and on the Assembly Floor

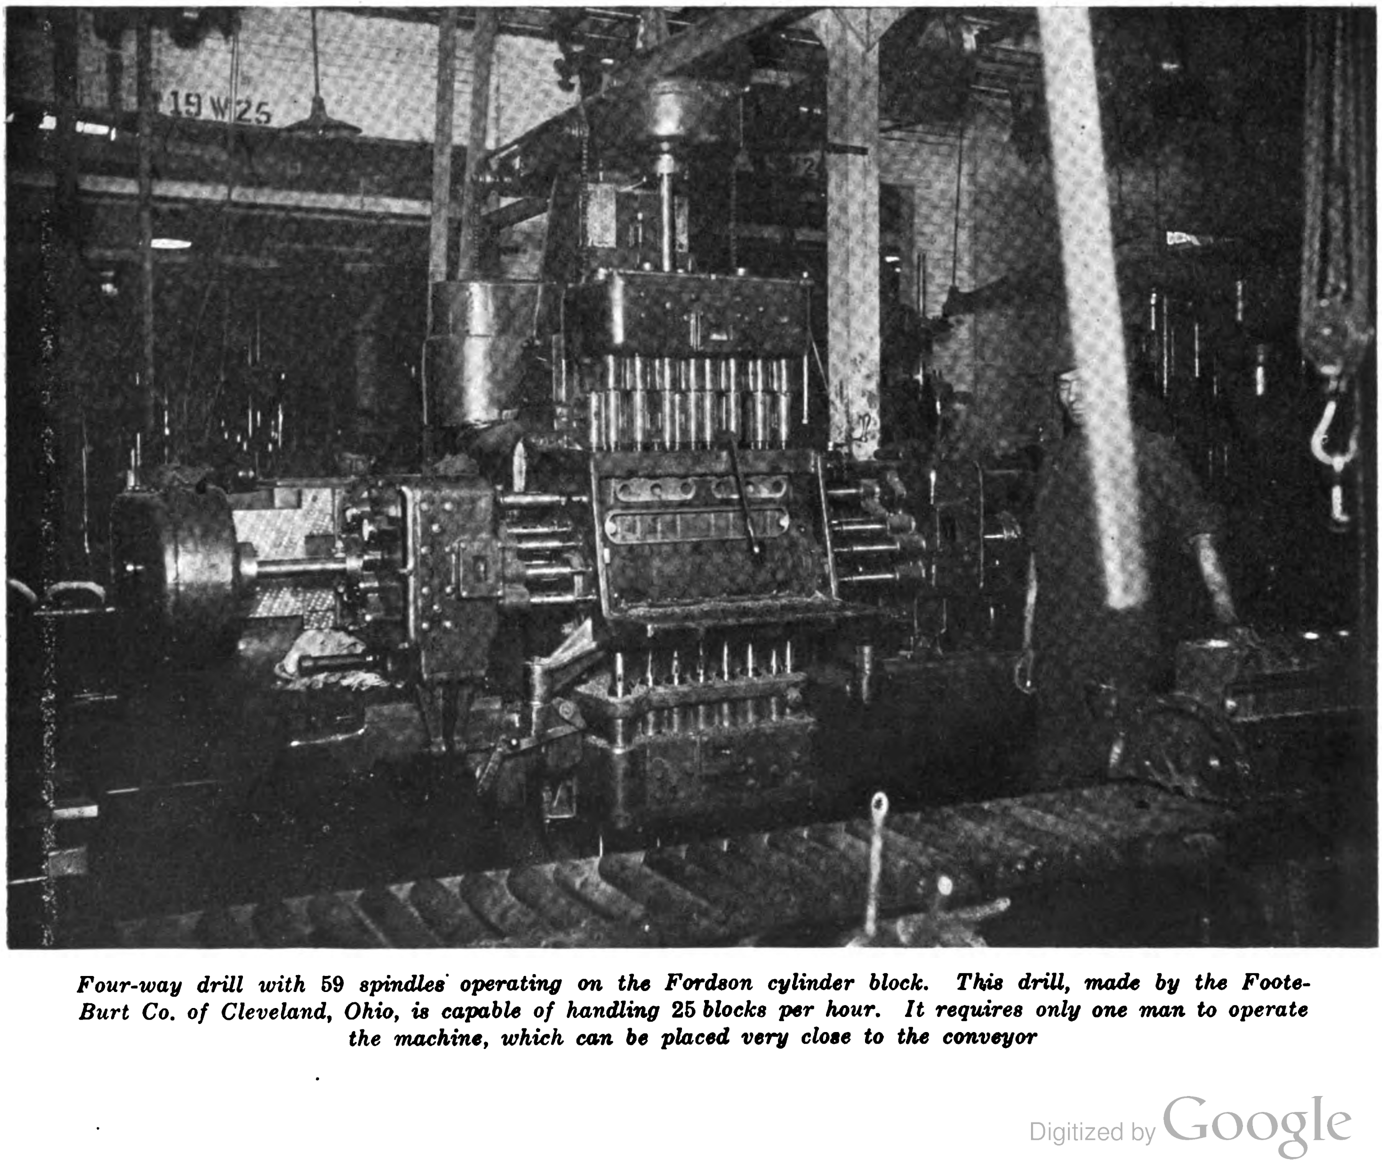
Description of Tools and Conveying Apparatus Installed in the Tractor Works of Henry Ford & Son to Eliminate all Unnecessary Handling and Motion of Parts

By J. Edward Schipper

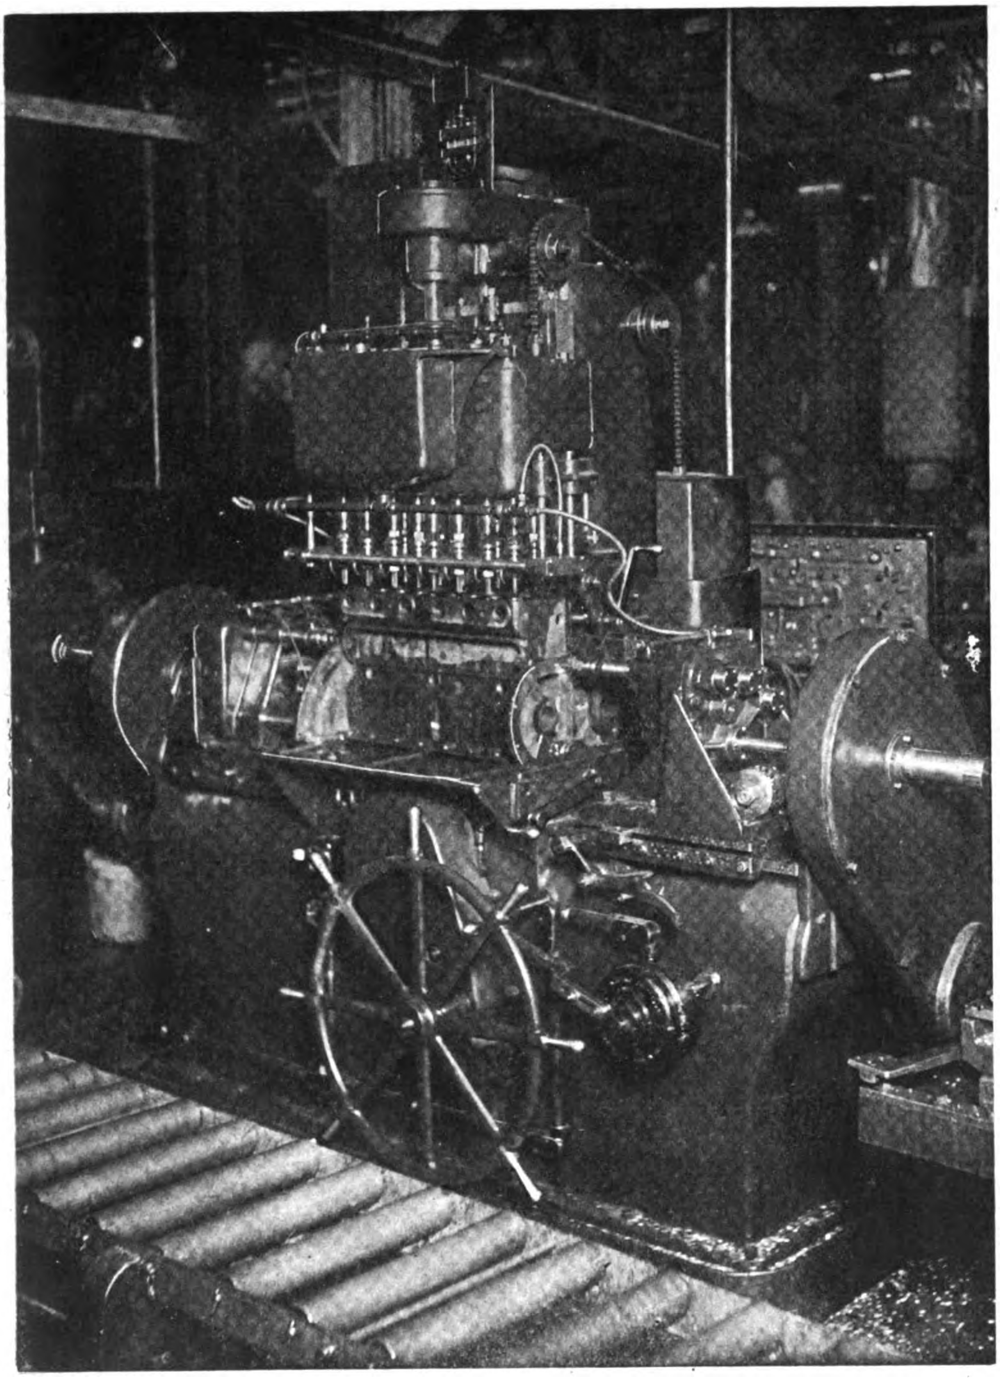
SMOOTHNESS of flow and regularity are prime essentials in manufacturing processes if the greatest efficiency is to be secured. Manufacture and assembly which proceed along the lines of regular geometric figures are generally highest in efficiency. The simplest form of progression is, of course, along a straight line, but manufacturing progression may be in a circle, an ellipse, or a rectangle, and frequently it is in the form of a straight line, with shorter feeding lines which enter this straight line at different points.

The ultimate object in the use of conveyor systems and special machinery is to secure this smoothness. Where a machine does the work of two, it reduces the amount of variation from straight lines or other regular geometric progression by a large percentage, because the very act of taking a piece off a conveyor, putting it on a machine and back on the conveyor again constitutes a deviation from the straight line of travel.

The illustrations are typical examples of the use of conveying apparatus and of special machinery at the plant of Henry Ford & Son, Dearborn, manufacturers of the Fordson tractor. The gravity conveyor system is



Four-way drill with 59 spindles operating on the Fordson cylinder block. This drill, made by the Foote-Burt Co. of Cleveland, Ohio, is capable of handling 25 blocks per hour. It requires only one man to operate the machine, which can be placed very close to the conveyor



A three-way tapper made by the Foote-Burt Co. of Cleveland, capable of handling 30 Fordson cylinder blocks per hour and tapping in three directions at the same time

used here to advantage, and there are a number of special machines of which those shown are very good examples.

The rotary milling machine shown is a product of the Ingersoll Co. of Rockford, Ill., and is capable of handling six blocks at one time, milling both ends of the block. In place of the reciprocating table, which is the cause of much loss of time in returning idly, this machine has a continuous rotary table which practically eliminates the loss of time due to setting up. Besides this, the machine takes both the roughing and finishing cuts. The two sets of milling cutters are apparent in the view of the machine. As will be noted, the machine itself is compact and can be set very close to the conveyor system, requiring little deviation from the conveyor line in order to place the block on the machine. The cylinder blocks shown are for the Fordson tractor engine, and it requires only 3 min. for a block to be completed on the machine. When once started, the machine is run continuously, there being a constant feed of blocks to the milling cutters.

The rotating table gives continuous motion because it is always proceeding in one direction and there is no necessity for the quick return movement common on reciprocating table machines.

Another special machine the use of which tends to keep the work close to the conveyor system is the four-way drill. The gravity conveyor used for passing the work along is shown in the foreground and the machine is directly behind it. The four-way drill has 59 spindles and is capable of handling 25 of the Fordson cylinder blocks per hour. The machine is a product of the Foote-Burt Co. of Cleveland, Ohio. It is handled by one man, and once set up is a simple machine to operate, because it is merely a matter of alignment with the jigs. Of course a machine of this kind must be so designed and laid out that the dangers of drill breakage are practically nil, because it would be very poor efficiency to have the entire 59 spindles held up due to the failure of one drill. This is a matter of speeds and drill quality, and the problem is readily solved by keeping the factor of safety just as high as possible on machines of this kind.

In using the gravity conveyor there are opportunities for placing inspectors at strategic points where they will be able to perform their work without interfering with the machines. One of these points is where the conveyor turns a corner, such as is illustrated. This particular illustration shows the inspector on the finished cylinder blocks, who can use his gages to advantage because he is located at a corner of the conveyor. This gives him free arm motion on both sides and allows him to work on either the end or the side of the blocks. The gaging operations performed at this point are checking the bearing diameter and the amount of metal on the face of the cylinder casting.

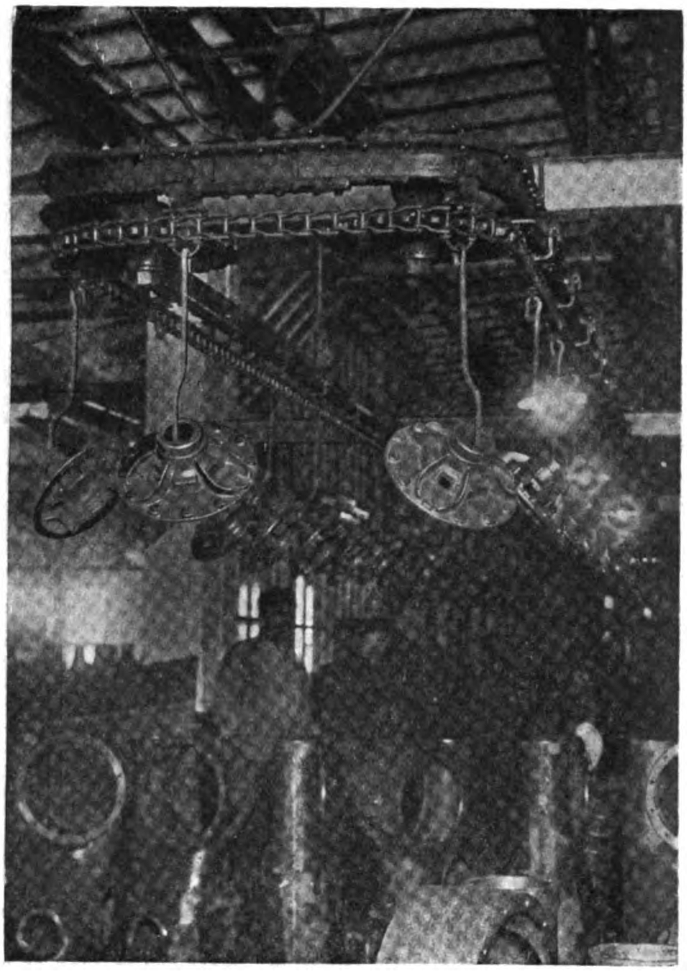
This particular inspection requires about six gages, which can be quickly used and the block pushed along at right angles to its previous course. This conveyor is the same as that shown in previous articles on Ford assembly methods, and illustrates the manner in which the cylinder blocks are brought directly to the assembly department without any intermediate storing operations in the finished parts stockroom.

Where the parts are not large enough to necessitate the use of a gravity conveyor and where other forms of chain conveyors fail, an overhead system such as illustrated can be used to advantage for bringing the work to the machines. The castings shown hang on hooks from an overhead chain carrier which passes around, bringing the work to the various machines. The operator on a machine simply reaches up and takes off a casting, performs his operation on it, and then hangs it back on the hook. When all the operations are complete, or at periodic intervals, the castings are removed from the hooks and placed on the conveyor, which travels down into the assembly department. In the foreground of the illustration showing these parts on the overhead chain can be seen finished transmission housings for the Fordson tractor, which are end to end on the gravity conveyor on the way to the assembly department. Thus it is apparent that with this overhead chain system it is possible to pass underneath with the regular gravity roller conveyor, and there is no trouble in the two lines crossing each other, as would be the case were they both on the same level.

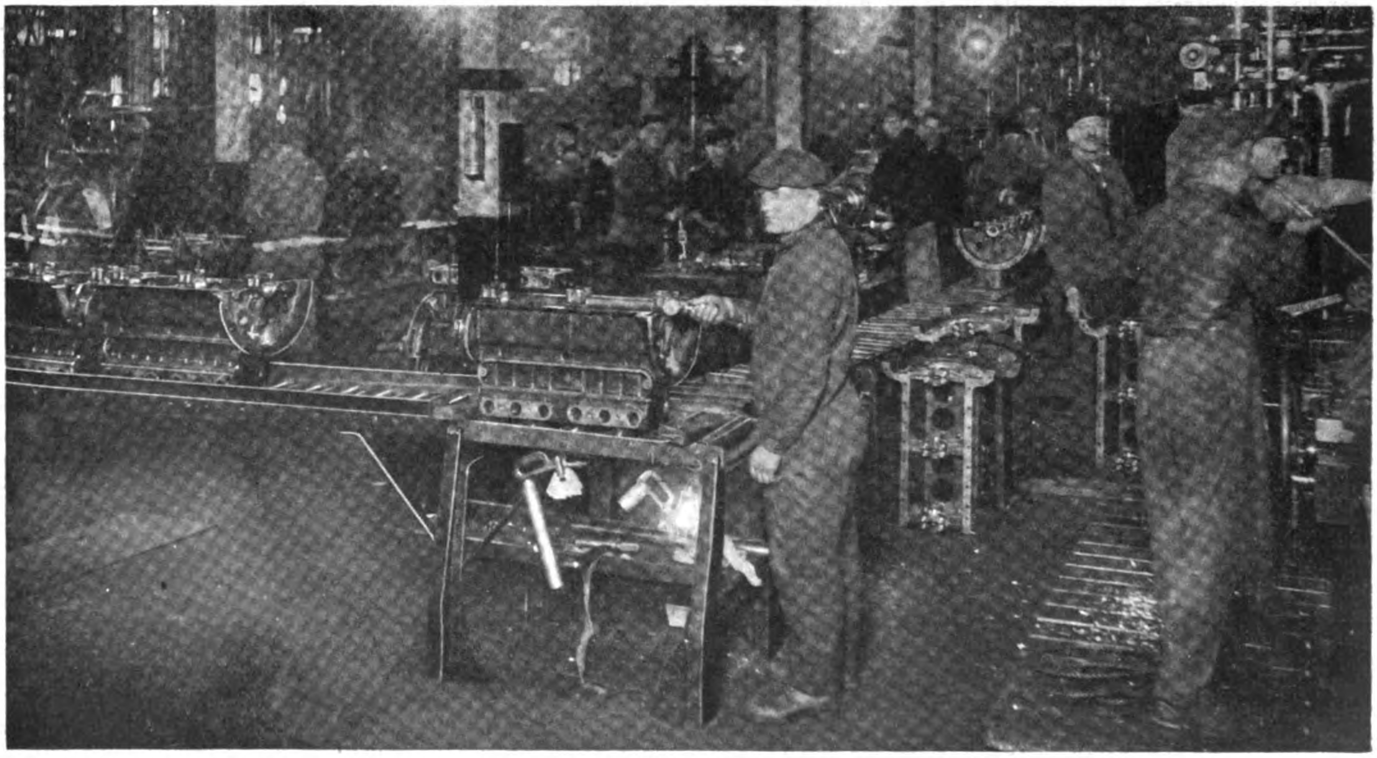
Sub-Assemblies Handled as Feeders

Feeding into assembly lines and manufacturing lines are always sub-operations which cannot be put in the continuous progressive system, because to do so would make the progressive line too long, or would complicate manufacturing problems. The solution for problems of this kind is to handle sub-assemblies or sub-manufacturing operations as feeders and allow them to come in as branches of the main line. The sub-assembly work shown on the worm wheel is a good example of this; the arbor pressing operations and electric drilling work can readily be handled to one side of the main assembly line, and the sub-assembled parts can then be sent along the gravity conveyor to the main line, reaching there at a point where the parts are required.

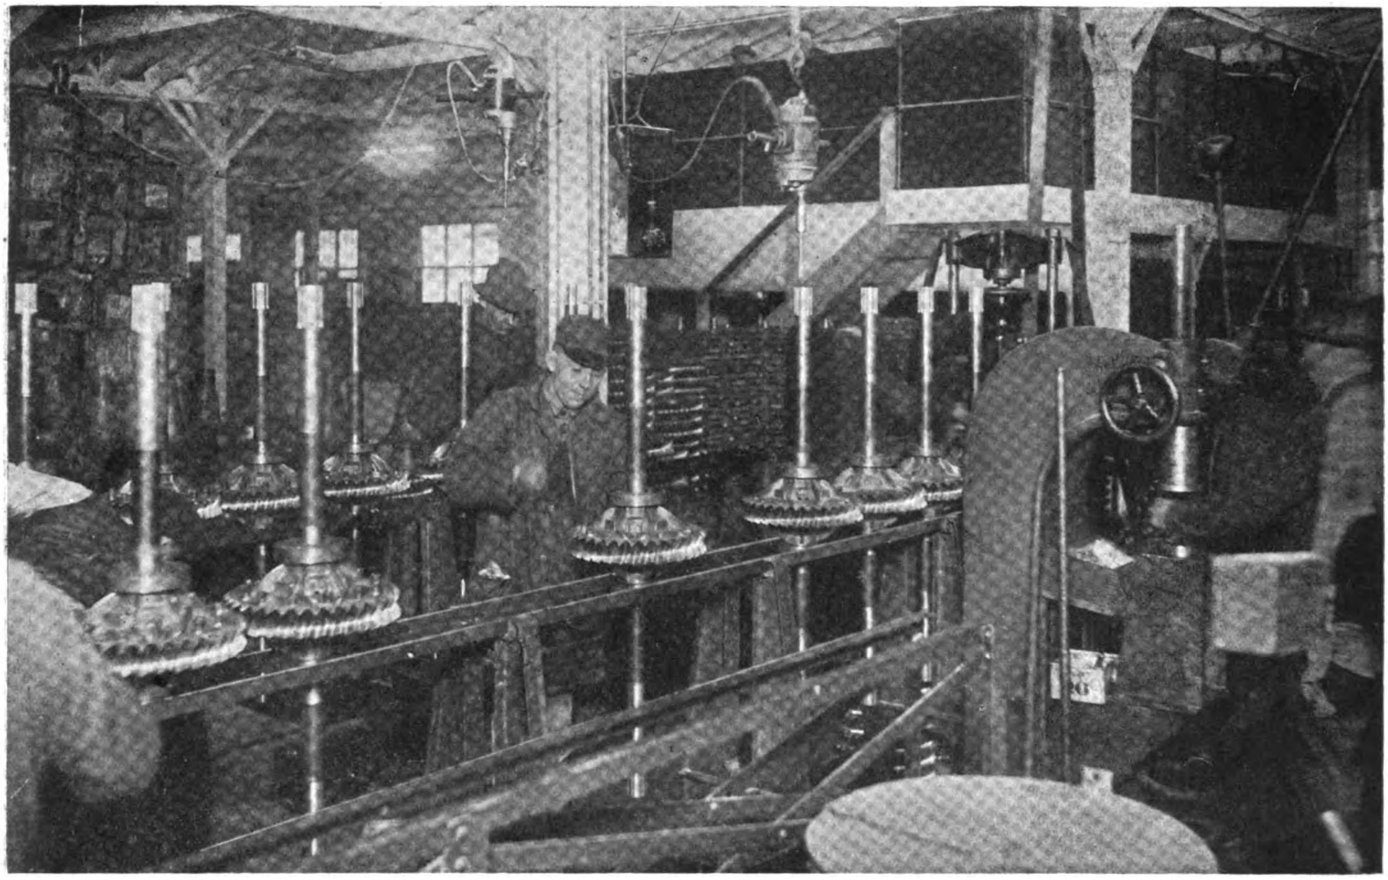
This method of handling the work is in common use at the Fordson factory and works out very well, indeed. The parts for the various sub-assembly jobs, such as



Overhead chain carrier used to bring the work to the machines and to eliminate storage on the floor. In the foreground are transmission housings on a gravity conveyor crossing the overhead line



Inspector stationed at a turn in the conveyor line. This insures freedom of motion in all directions



A sub-assembly feeding line by means of which the worm wheels and axle shafts on the Fordson tractor are sub-assembled and fed to the main assembly line. The arbor press operation is shown to the right of the illustration. Note the method of supporting the electric drills overhead

bolts, cap screws, etc., can be placed in pans beneath the gravity conveyors or racks, so that it is possible for the workman to always have a supply at hand. There is the objection of stooping for these parts; but whether or not that objection is serious depends on the number of pieces to be picked up and the possibility of putting a small supply at hand on a level with the job.

These random examples of methods in keeping the progressive line to a straight geometric figure are typical of the way the work is handled at the plant of Henry Ford & Son, Dearborn. The methods are those which should be adopted by any shop which is making a special study of motion efficiency, as both by the use of special machines and by the use of conveying apparatus which brings the work close to these machines and holds it to the preconceived line, the deviations are kept at a minimum and the total amount of travel of the work is kept as low as possible. After all, the efficiency of manufacture can be determined quite closely by the total distance traveled by the piece in its progression from a raw part to finished stock. The story can always be told by studying the distance traveled, and good conveying systems and wisely chosen special machinery will reduce this total travel to a minimum.

Exide Tractor Type Batteries

THE Electric Storage Battery Co. of Philadelphia, manufacturer of the well-known Exide batteries, has made a careful survey of the tractor field, and as a result has reached the conclusion that, while passenger automobile batteries are not adapted to this service, there are no conditions which cannot be met by a properly designed battery. It has therefore brought out a complete line of tractor type batteries.

These batteries have been subjected to the most severe shock and vibration tests, and have withstood these tests successfully, we are informed. The plates are very heavy and of rugged design. The separators are of the combination treated wood and perforated hard rubber type. This separator combines the good points of wood and hard rubber, and is employed where the conditions are very severe, as, for example, in mine locomotive service. Plate groups are supported on strong rubber bridges, an additional protection against shocks or vibration. Jars and covers are of Giant compound, and breakage is said to be practically eliminated. Covers are of the double-flange type, permitting effective sealing. With this construction, the cover supports the top of the jar from the outside as well as the inside, so that it cannot break away from the seal, and thus a permanently tight joint is rendered possible.

Elements are proportioned to fit the jars tightly, and extra heavy sealing nuts are used on the pillars to anchor them in place. Jars are set in compound in the carrying cases, and as an additional precaution the latter are equipped with through bolts so that the sides can be drawn together, holding the jars firmly in place.

Intercell connectors are of flexible copper, to prevent crystallization and consequent breakage under severe vibration, and are lead-plated to prevent corrosion. Terminal connectors are standard clamp lug type.

The initial cost of the Exide tractor type batteries is somewhat higher than that of the automobile type, but it is claimed that from the standpoint of service they will prove considerably cheaper, as the rugged construction employed will not only result in greater reliability and freedom from trouble but also in a much longer life.

Airplane Supply System of the American Army in France

(*Continued from page* 989)

and until the necessary machinery and organization have been brought into existence no amount of enthusiasm, no amount of punch, will produce tangible results.

France possessed the machinery and the organization as the result of three years' intensive effort under war conditions. America was just getting her machinery and organization together, and having to learn, as all those before her had learned, by her own mistakes. Until the American machinery could be put into motion, the best, indeed the only sensible plan, was to intensify the output of the French machinery to such a degree as to enable it to supply the American army's needs.

Consequently the moribund contract of Aug. 30, under which France was to supply America with 5000 airplanes, was wiped off the slate and a new contract was entered into between the French and the American Governments, by the terms of which France was to place at the disposal of all the large American units, such as army corps, divisions, etc., the same aviation material in quantity and quality as if corresponding French units were involved. This contract, which was put through in six weeks' time, went into effect on May 3, from which date the American Air Service got into its stride and went ahead at an increasing rate. As France was going to be the temporary furnisher of aviation material to the American army, and as 90 per cent of the French aviation industry was stationed in and around Paris, it was necessary that Paris, and not Tours, should be the headquarters of the Supply Section of the American Air Service.

In order to fully appreciate the difficulties under which the early work had to be carried out in France, it must be understood that it was not known by anybody how big an army America would have, whether the United States troops would operate as a separate army, or whether they would be attached as units to the various Allied armies. In other words, an Air Service had to be created to meet the requirements of an army of unknown size and nature. When, in the spring of 1918, Germany began to drive home her crushing and, as she hoped, final blow, and in consequence the Allies had to send an urgent appeal to America for immediate assistance in the field, the task was thrown on the Air Service of meeting big, urgent, deadly pressing calls.

Without in any way deprecating the importance of the preliminary work which had been carried on up to that time, it may be stated that the Supply Section of the Air Service took off its coat and rolled up its sleeves in the spring of 1918 and had no time to wipe away the perspiration until the unexpected armistice called for a halt on Nov. 11. It was during that period of nine or ten months that practically the whole of the 46 squadrons were formed, sent into the field and maintained there, and that the 6625 airplanes were obtained for the A. E. F.

All the airplanes built for the French army in the factories located in and around Paris were sent to the big depot at Le Bourget, on the eastern suburbs of the city, where they were completely equipped and despatched under their own power to the front. As France was to meet the needs of America until the home factories were in a position to produce, it was quite natural that space should be reserved for the American Army at Le Bourget. Germany was evidently fully aware of the great importance of the French air depot on the plains to the east of the city walls, for on several occasions she sought to destroy it by aerial raids, and during the month of March made a big concentrated night attack during which considerable damage was done. Among the machines destroyed were a number of Spad fighting planes for the American army.

Orly Field Established

As a result of this attack, the French decided on splitting up their own forces and gave orders for the American service to evacuate Le Bourget without delay. While the original cause of this removal was unfortunate, the outcome was most satisfactory, for faced with the necessity of securing its own quarters, the Supply Section of the American Air Service decided on the construction of Orly Field, the importance of which to the A. E. F. cannot be overestimated. On the main road from Paris to Fontainebleau, about 8 miles south of the former city, there lay a series of absolutely level fields, given over to farming, but devoid of hedges and ditches and con-

Nieuport airplanes used for training American pilots in France

A part of the American city built at Romorantin

sequently easily convertible into an air depot and flying ground. Within five days the American Air Service was authorized to take possession of this ground. This constituted a record, for usually these requisitions cannot be put through in less than six weeks. If any incentive to quick action was required, it was to be found in the threatening German activities on the Somme, accompanied by air raids and long distance bombardment of Paris, which began about that time.

On March 31 the Sixth Company of Motor Mechanics Regiment came up from Tours on 25 trucks, established themselves on the field, and began to lay the foundations of an air depot which six days later was able to receive the first airplanes from the French factories, and within three weeks to despatch the first planes from Orly to the front. When this ground was taken over it consisted of monotonously level fields without a building on them, with a fine granite paved road running through them, with convenient railroad lines, with the River Seine on the eastern edge, and just to the south the old Juvisy airdrome, where the first Frenchmen had learned to fly on Wright machines, and from which Count De Lambert had started on what was once a sensational flight around the Eiffel Tower. Seen from a height of 3000 ft. above Orly, the aviator had below him the city of Paris, the French airplane and engine factories and a regular series of French airdromes. The situation was [illegible]h that French civilian pilots, having planes to de-[illegible] from the factories to the American army could [illegible] to an altitude of 2000 or 3000 ft., shut off, and [illegible] Orly. It was a little economy in gas which the [illegible]rs were not above despising.

Imm[illegible] after the signing of what came to be known as [illegible] May 3 contract, a requisition was placed with the French for equipment to meet the needs of 94 squadrons, the supply of this of course to be spread over a rather long period. The French lived up to the spirit of this contract in a whole-hearted manner. Not only did they change all their production plans, but they altered all their arrangements at the front in order to meet the requirements of the American army.

Orly was designed with a capacity of 25 planes a day, but under the urgency of the calls from the front and in order to meet the rapidly increasing requirements of the army, it worked at all times beyond this capacity. By the middle of the summer it had established the record of 91 airplanes despatched on one day from this ground for the front, and from the end of March, when the agricultural fields were taken possession of, to the eleventh day of November there were sent out of Orly a total of 1800 planes. The ferry pilots who took these planes up to the front covered a total distance of 403,000 miles, equal to sixteen times around the world. This big mileage was obtained with a total loss of six lives, although owing to the extreme urgency of the calls it was often necessary to order deliveries to be made when weather conditions were unfavorable, and to give to pilots machines with which they had had little previous experience.

Although the French Government undertook to meet the immediate needs of the United States Government, this did not imply that the American Air Service had to sit by with folded arms and watch the planes come in. Under the contracts French makers delivered airplanes in about the same condition as automobiles were delivered ten years ago. The finished article consisted of a plane and an engine, which, while constituting a flying machine, was unfit for service at the front until it had been equipped with navigating instruments, supplied with a gun or guns, given wireless telegraphy sets, bomb carriers, and all other auxiliaries necessary for a fighting plane.

Equipment on Progressive Production Plan

Test groups composed of a pilot, a group inspector, an airplane mechanic, a motor mechanic and a clerk had to be formed to go to the various French airdromes around Paris and take delivery of machines for the American Government. These tests were severe, for out of 3394 planes presented by the French only 2126 were accepted immediately. Five hundred and ninety-seven planes were accepted after one rejection, 191 were accepted after two rejections, and a few were only admitted after six rejections. In all 1814 planes were rejected at various times, and of these 399 were never accepted. In carrying out this work the pilots made more than 5000 test flights.

Orly field, with its 78 hangars and scores of other buildings, its miles of cinder track and acres of perfect flying ground, was laid out on a progressive factory

system, with the sheds at one end for receiving new planes, and the other buildings in proper order according to the equipment to be added. In the first shed the plane would receive its navigating instruments; moving along, it would get its wireless equipment, if designed to receive this; next it would get its gun or guns, and would be taken up to the firing butts to be tested for accurate mounting of the gun and for synchronization. As it moved from shed to shed each machine was tested and reported on, until finally it went out for its final test flight fully equipped.

Having been pronounced perfect in every respect, the machine would take its place on the starting line marked across the field, from which point 25 to 90 machines were despatched to the front every twenty-four hours. On an average this work of receiving, equipping, testing and dispatching a plane to the front occupied two to three days. All the machines included in the initial equipment of a squadron went out complete with every requirement. Of the replacements sent out to make up losses due to wear and tear and enemy action, 50 per cent were completely equipped, and 50 per cent without equipment, for out of the crashes it was always possible to save some of the accessories.

At the time of the armistice Orly had a staff of 323 officers and 2283 enlisted men who were living on the field in sheds and buildings erected by the American army. This work of erecting buildings and fitting up machinery had to go on concurrently with production.

Every foreign airplane intended for the American Service had to pass through Orly. As the great majority of these machines came from French factories, they had to be flown but a short distance; but England and Italy also contributed, and their machines came under their own power to Orly. The Italian machines had to be flown over the Alps, and in order to meet these conditions the Italian Government constructed an emergency landing ground on top of Mont Cenis pass, 9000 ft. above sea level.

American Planes Fitted Out at Romorantin

While this big effort was being exerted in conjunction with the French, an equally big program was being developed for the reception of airplanes from America. At Romorantin, a little town situated on that all-American line from the Atlantic to the Vosges, there was established in early March what was officially known as Air Production Center No. 2. The French authorities turned over to the Air Service about 50 acres of thinly wooded or barren land, and on this there was erected within a period of 10 months a real live American city with 2,900,000 sq. ft. of constructions, 36,000 lin. ft. of made roads, 55,000 ft. of railroad, nearly 8 miles of water line and about 5 miles of drains, and adjoining it a flying field of 425 acres of prepared ground, the whole receiving a personnel of 12,000 officers and men.

Romorantin's duty in the scheme of supplying the flying forces was to receive American-built airplanes, to assemble them, to equip them, and dispatch them to the front. In addition to this it had to provide for all spares and replacements of planes, engines and airplane equipment. It had to receive all wrecked planes sent back from the front, repair them or salvage them, according to their condition.

The preparatory work, which consisted of clearing the ground and erecting buildings, began in early March, 1918. Lumber was scarce, machinery and equipment were not coming in from America and were hard to find on the French market. All that month of March the preparatory work went on and by the beginning of April work was sufficiently advanced for starting on preparations for the assembly of American-built planes then reported to be on the water.

It was on April 11, 1918, that the first American-built DH-4 airplane, designed to be flown with a Liberty engine, was unloaded from the American freight cars running over the American-built railroad line from Saint-Nazaire to Romorantin, and one week later this same plane—the first of a big and ever increasing series—was ready to make its trip over the lines into Germany.

From that time to the signing of the armistice Romorantin worked steadily, day and night, on the task of receiving, assembling and dispatching American-built airplanes to the armies in the field. Between May 11 and Nov. 11 there were sent out of these huge shops 1213 American planes, all equipped with the Liberty engine. Of these planes 1087 were in active service over the lines, and 67 were in hand for delivery when Germany threw up her hands.

Romorantin enjoyed an ideal geographical situation. Almost in the center of France, right on the main line of communication, it was yet sufficiently far from the fighting line to be undisturbed by enemy action. These 200 miles had to be covered by the planes under their own power, deliveries being made by ferry pilots, as in the case of the foreign planes sent out of Orly. Notwithstanding the distance, only 5½ per cent of the planes were crashed during delivery, and of these accidents 25 per cent were due to fog, rain or other climatic conditions beyond the control of the pilot.

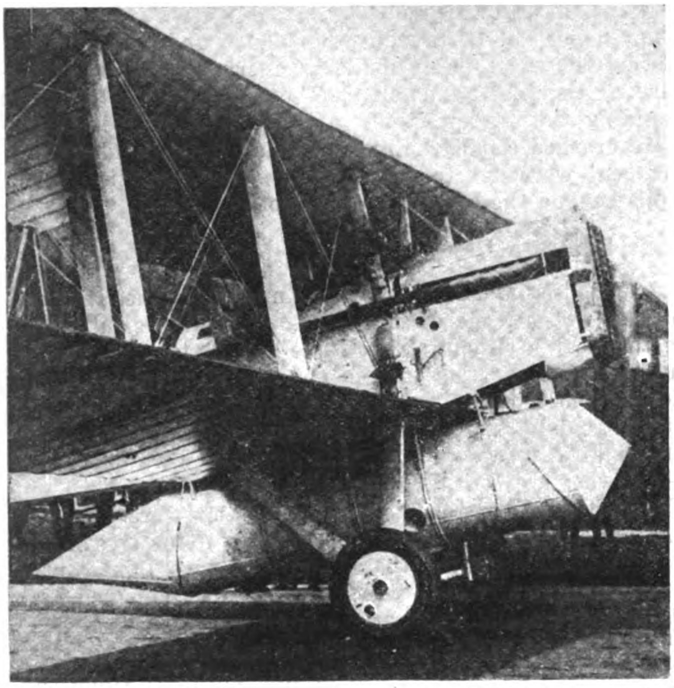
Sixty Planes a Day

Assembling and shipping new American planes was the biggest but not the most difficult, of the tasks intrusted to the staff at Romorantin. The size of the job can be judged from the fact that in one day 60 airplanes were flown from Romorantin to the armies. Up at the front, at Chateau-Thierry, in the Argonne, in Champagne, east of Dunkirk, wherever American aviators were operating —and they were to be found all along the line from the North Sea to the Swiss frontier—planes were smashed and were being sent back to Romorantin for treatment. During those eight months of heavy fighting Romorantin received 1184 airplanes which had been so damaged that the squadrons and parks at the front were unable to handle them. Of these planes 899 were American and 295 were of foreign origin. Out of this total 101 American planes and 207 foreign planes were salvaged, and 756 American planes and 40 foreign planes were repaired and delivered into service again, making a total of 796 airplanes returned to the army. In addition, when the armistice was signed there were 52 American and 48 repaired foreign planes on hand.

Under war conditions the life of an aviation engine is short. Each squadron in the field is equipped with limited repair facilities and is supposed to carry out work which can be executed without impairing the mobility of the organization. But in order to make possible any extensive amount of repairs it is necessary to provide each unit with a considerable stock of spare parts. But in France spares, whether for airplane engine, airplanes, or for automobiles, always have been exceedingly difficult to procure. French makers always preferred to build complete units rather than spares for the same, and from America there always seemed to be more difficulty in getting spare parts shipped to France than in securing whole engines. In consequence of this, Romorantin was made the great center at which aviation engine repairs should be carried out. When there was a defect which the squadron mechanics could not immediately remedy,

the engine was put aboard the railroad car and sent back to these centralized shops for treatment, its place being taken by a replacement which might be new or overhauled.

In considering this work it must not be imagined that the aviation material could be divided into American and foreign. While the United States practically limited itself to one type of engine and plane, the European material which had to be received and operated on comprised 41 different types of airplanes and 23 different types of engines. Before they landed in France not one man in a thousand had seen a foreign plane or even had the opportunity of reading a description of a modern airplane engine. Men had to be trained to fly these different types of planes; riggers had to learn to erect and adjust them. Mechanics had to study each different type of engine, to know how to repair them, assemble them and adjust them. Among the technical personnel were many first class automobile mechanics, but few if any of these had seen a foreign aviation engine before donning the uniform, and yet they had to handle such different types as the Renault, Rhone, Gnome, Fiat, R. A. F., Anzani, Beardmore, Hispano-Suiza, Salmson, Clerget, Lorraine-Dietrich and Peugeot.



To get deliveries of these foreign engines and planes necessitated negotiations with the Governments of France, England, and Italy, and even business connections with such neutral nations as Spain and Switzerland, This meant that hundreds of men who up to the outbreak of the war had never been outside the United States, had to make themselves acquainted with foreign business methods and handle one of the most highly specialized and technical subjects in a foreign language. Had any private business concern in America considered the possibility of a European business of this magnitude, it would doubtless have spent two years in laying plans and picking out a specialized personnel, before attempting to do any real work.

The call on the Supply Section of the Air Service fluctuated with the severity of the fighting. The course of the war might be followed merely by examining the diagrams of requisitions and deliveries. But from March to November, 1918, there was one continuous battle, and consequently one continuous call, with minor fluctuations, on the Supply Section. At Romorantin alone there were received in seven months 50,000 tons of material and distributed 17,000 tons, or a daily average of 322 tons. Among this material were 2600 propellers received and 1600 despatched; 1526 airplane wings received and 1039 sent out. The greatest strain came in the month of August, when the Supply Section sent out to the armies in the field a total of 950 airplanes.

The two big centers, Orly and Romorantin, were dependent on the base ports for their supply of material. From a military standpoint the whole of France and a small portion of England were divided up into zones, which comprised the various Base Sections, the District of Paris, the Intermediate Zone, and the Zone of Operation. At all the big base ports there were aviation officers and men whose duty it was to receive material and get it through as expeditiously as possible to its destination, which might be Paris or Romorantin or in extreme cases the Intermediate Zone.

British Airplane Which Attempted Transatlantic Flight

THE Short Bros. biplane which fell into the Irish Sea on its attempt to fly across the ocean with Major Wood as pilot. The machine originally was built to carry a giant torpedo for attacking the German fleet. An aluminum gasoline tank with a capacity of 600 *gal. now takes the place of the torpedo. The wing span of the machine is* 34 *ft. and it is fitted with a Rolls-Royce engine of* 360 *hp.*

The International Labor Convention Analyzed

A Manifestation of a Common Purpose Among Labor Organizations of the World—The Nine Clauses and What They Indicate in the General Tendency of Labor Affairs

By Harry Tipper

LAST week there was printed in AUTOMOTIVE INDUSTRIES a summary of the Bill of Rights which was approved by the International Commission on labor legislation containing nine clauses that are proposed for insertion in the treaty of peace. The additional information which is available contains the text of the organization machinery by which the International Labor Conference is to function and through which its operations are to be made effective.

While this convention is not likely to become effective immediately and is not concerned in the present operations of a manufacturing plant, it is sufficiently important in its departure from precedent, in its indications of a common purpose among the labor organizations of the various countries and in the conditions of its recommendations, to make it worth while to examine the matter with some comment upon the developments.

Nine countries participated in this Commission: the United States, the British Empire, which, however, includes Canada, Australia, New Zealand and South Africa as self-governing colonies, France, Italy, Japan, Belgium, Cuba, Poland and the Czecho-Slovak Republic. This means that the most important manufacturing countries outside of the central countries of Europe, were interested in this International Labor Conference.

It is significant that while the main peace conference has been disturbed by the difference in national aims and the difficulty of their adjustment by the jockeying of political bodies, the International Labor Conference has gone ahead and with little trouble apparently has drawn up the nine clauses which constitute the Bill of Rights for incorporation in the treaty of peace.

We have had occasion to remark a number of times that labor knows how to co-operate in organizing for common purposes better than any other section of the population, and it is evident, from the conclusion of this conference, that the representatives of the different countries on this International Labor Commission have seen the necessity of establishing similar labor regulations upon certain broad lines if the international competition was not to interfere with the improvement of the condition of labor in the more populous and more advanced countries.

The actual Bill of Rights which has been presented for inclusion in the peace conference contains items which are of importance on account of their indication of the general tendency in labor affairs and their influence upon legislation in this country.

There is a specific clause dealing with this question admitting that employers and workers alike are allowed the right of association for all lawful purposes. Of course, this has been tacitly recognized by most manufacturing groups in this country, although this recognition has not taken the definite and effective form which it has taken in Great Britain. There are still a good many employers who question the right of the worker to organize and there are a great many groups of manufacturers who are still attempting to destroy the labor organizations with which they are concerned.

The recognition of the right of association and the recognition of its place in the relations between capital and labor must come definitely in the near future in any case, and, therefore, this clause in the treaty is merely a consolidation into the treaty of peace of the general opinions prevailing in the countries concerned.

Child Labor

Because of the control of labor regulations within its borders by each State in the Union, and the difference in public opinion in the different States, there has been no unanimity in the regulations concerned with the question of child labor in this country, and in this respect the United States is considerably behind the more important countries in Europe. Of all the matters pertaining to labor which can become the subject of State or national regulation, the conditions under which children may enter industry are the most important. The health, the education, and the outlook of the children directly affect the productive capacity, the political ideas and the social incentive of the mature.

In Great Britain the physical effects of the period in the middle of the nineteenth century, when factory work was done by thousands upon thousands of young children, is not yet eliminated. The physical deterioration, due to this industrial nearsightedness, is one of the difficulties which are affecting that country.

It should be considered, however, that the regulations in respect of the employment of child labor in Great Britain are to-day very strict, and the United States, as the most important industrial country in the world, has no definite policy in connection with this matter. It will become necessary for this country to decide, if this Bill of Rights is included in the treaty of peace, whether its ratification will include the three clauses which specifically regulate the employment of children in industry or commerce.

The Right to an Adequate Wage

Those clauses which deal with the right of labor to secure a wage adequate to maintain a reasonable standard of life are important more for the definition of this item than for any change which it would mean to industrial practice in this country, at any rate, in the metal trades and machinery industry, where the condition of the worker has been established on a basis which gives each worker this adequate wage on the basis stated.

The following clause, however, which deals with the pay to be given to women workers is of considerable importance to the machinery industries which have begun to employ large numbers of women workers, particularly since the war broke out.

This clause demands equal pay to women and to men for work of equal value in quantity and quality. Under the present system of handling labor pay, it has been customary in a good many plants to secure women workers for a reduction in the wage for given classes of work from that required by men working at the same job. The practice in this respect would be altered if the various States in this country decide to ratify this clause in the treaty.

The only other item of importance in this array deals with the demand for a weekly rest for all workers and the limitation of hours to eight hours a day, or 48 a week.

The machinery of organization proposed in this International Labor Commission provides that the recommendations of such International Commission shall be treated in the case of a federal power as a recommendation only, where it is impossible for the Government to enter into a draft convention. This means that on labor questions, which are under the control of the various states in this country, most of the provisions contained in the Bill of Rights would have to be treated as recommendations only and recommended by the national government to the states for adoption. They are not of importance, therefore, as indicating any immediate or pending action on the part of the government in this country in its agreement with the Allies as to peace terms, but they are of importance in indicating the solidarity of the aims of labor in the various countries, the recognition of certain general regulations which must exist internationally if the labor position is to be safeguarded and the strength which can be used by the labor bodies in the various countries in the attainment of these provisions which they are convinced are internationally desirable.

This whole report should convince the manufacturer of the power which has been secured by the worker during the war and which has changed the conditions to which the industry must look forward and to which its operations must be adapted.

It is evident that the inclusion of this Bill of Rights in the treaty of peace would bring these nine clauses definitely into the political arena in this country and make them matters which must be decided either one way or the other by the political bodies. Such an event would also initiate the action of the various states upon regulations of a uniform character and have an additional political, civic significance in that way. Whether these clauses are actually adopted in the making of the final treaty and whether they become operative in this country in due course after that time or not, the attention which has been given to them by their recommendation to the peace conference from the International Labor Commission will bring them into prominence and undoubtedly reinforce the propaganda which has been established already for the passage of some such regulations.

Manufacturers in the automotive field will do well to watch the tendency now exhibited in various states in this country for the promotion of legislation of a regulatory character on labor matters, such as the bills which were brought before the New York State Legislature for a minimum wage and a definite working day, considering this increased tendency toward legislative enactments in their decisions as to their own policy toward their own workers and toward their own organization plans. It is desirable that as many of these questions be settled between the owners of the industrial organization and the workers within that organization and that as few of them be left to regulation as may be. The extent to which regulation is demanded will depend very largely upon the extent to which the manufacturer takes these things into consideration and considers his organization plans and his own policy in his own plan with due regard to the tendency of public opinion and the general attitude of the labor bodies as shown in their demands and agreements.

British rigid dirigible on trial trip

Direct Selling in South America*

A Careful Study of Markets and Trade Conditions Essential—Selling Through Branch Houses, Traveling Representatives and by Mail—The South American Merchant—Terms and Credit

SOUTH AMERICA is one of the world's greatest potential markets. Its resources are enormous. It is awakening to its great commercial opportunities, and its future development promises to be rapid. Our country should participate in that development to the extent of its ability. During the war, with European markets largely cut off, South American business was thrown at our feet, but this condition will not continue much longer. European manufacturers are alert to the possibilities of this market, and it promises to be one of the most hotly contested in the world. Our share of the business will depend almost entirely on the efforts which we make to retain our present customers and develop new ones. If American manufacturers will awaken to full appreciation of the importance and magnitude of the South American market, and make whole-hearted efforts to develop it, there is no reason why we should not retain and increase in this field the leadership which the war made possible.—P. S. STEENSTRUP.

MOST products marketable in the United States can be sold in South America, but the country is so large and trade conditions so varied that a very careful study of conditions should be made before a selling campaign is launched.

There are three different ways of direct marketing: First, through branch houses; second, through traveling salesmen; third, by mail, through the use of letters, catalogs and samples.

Branch houses are not desirable for the small manufacturer or the manufacturer with limited sales; neither are they profitable for the manufacturer who is interested in foreign markets only when he has a surplus of products and forgets all about overseas business when the domestic market is able to absorb all the merchandise he produced.

For the manufacturer with ample capital and a staple product for which a large and sustained demand can be created, the branch house is the best selling method to employ in developing South American markets. The establishment of a branch house makes your business a part of the country and community, and gives you a standing which cannot be obtained by other methods. The South American, like the European, is favorably impressed by the appearance of permanency and he likes to establish business relations on a more or less permanent basis.

Branch House Essentials

The location of branch houses should receive careful consideration. If inland, they should be on a good railway or near as many different transportation systems as possible. The locations should be selected only after careful consideration of the markets which the branches would serve, labor conditions, local taxes, etc. The initial expense incurred in establishing South American branches is much greater than the cost of similar ventures in the United States. Many different forms of taxes and gratuities must be paid, and traveling expenses are much higher than in this country.

The selection of a branch manager is very important. He should be familiar with the languages, customs and business methods of the countries in which he is located, should have a thorough knowledge of his product, and command the confidence of his house. Unlike the American branch manager, who is in almost daily contact with his home office, the manager of an overseas branch is almost entirely on his own resources. He must be competent and resourceful and be able to make decisions on important questions without the delays incident to communication with the home office.

If market possibilities or finances do not justify the expenses and risks incident to the establishment of branch houses, the next best way to market your product in South America is through traveling salesmen and exclusive representatives.

Traveling Representatives and Local Agents

Great care should be taken in selecting your traveling representatives. Although good men are scarce, traveling is so expensive that you cannot afford any other kind. An unsuitable traveler is a very costly investment. Men developed in your own office will probably be found most satisfactory. They should know your product thoroughly, should have a good conversational knowledge of Spanish and Portuguese, or Spanish and French, and be dependable and adaptable. Personality and breeding are important in the South American field. Friendship is a valuable factor in business, and the exchange of social courtesies is an essential preliminary to the opening of business relations. Do not expect your representatives to show immediate results. It takes time and patience to establish a profitable business in South America and manufacturers who are not prepared to spend the time and money necessary for development work should not attempt to enter the markets.

In the appointment of local representatives or distributers great care should be used in the apportionment of territory, and also in the selection of the business houses. Only as much territory should be allotted as a distributer is able to cover thoroughly. While old-established business houses often make the best representatives, a young, aggressive firm with less capital than its older competitors, but with much more initiative, will occasionally get the larger volume of business.

After a distributer is appointed he should receive all possible co-operation from the manufacturer. Literature in the language of the country without prices, or with prices quoted in the money with which his customers are familiar should be furnished. Periodical advertising campaigns should be provided and all possible assistance and encouragement given the distributer to promote the sale of your products through modern, aggressive sales promotion work.

Many American merchants and manufacturers whose salesmen have never been south of the Rio Grande have by mail built up substantial and profitable trade relations with South America. The larger mail order houses are doing a large volume of business in this territory, and many of the larger New York department stores are receiving orders from the wealthy South Americans. Our export publications are now carrying advertisements of practically all known commodities from pins to locomotives

*Abstract of a paper read before the Sixth Foreign Trade Convention by Mr. Steenstrup, who is general manager of the General Motors Export Co.

and many of the advertisers never have had traveling representatives in South America.

For the merchant or manufacturer who does not wish to incur the expense of sending out traveling representatives, the mails offer a comparatively inexpensive and frequently effective medium for developing South American trade. Advertisements in our export publications bring good results; and if desired, this form of advertising may be supplemented by circularizing lists of prospects, which may be obtained from daily commerce reports, foreign trade directories, business associations, banks with South American branches, United States consuls and the companies which furnish lists of various kinds. Advertising matter for use in a direct-by-mail campaign of this kind should be prepared with the greatest care. Catalogs and circulars should be well illustrated, printed in idiomatic Spanish, or in Portuguese if for distribution in Brazil, and when prices are quoted they should be in the money of the country in which the literature is distributed. All inquiries should receive prompt and careful attention, and replies should be in the language of the correspondent.

Before exclusive agencies are granted, a most thorough investigation of the prospects and possibilities of the territory which the agent proposes to cover should be made. Sometimes a merchant handling competitive lines manufactured in European countries places a small order with an American manufacturer for the sole purpose of obtaining an exclusive contract and excluding the product from the market during the life of the agreement.

The South American Merchant

Business establishments in South America are of two kinds, native and foreign, with business houses owned by foreigners greatly outnumbering those owned by the natives, especially in the large cities. Many of the native merchants are Mestizos, of mixed Spanish and Negro blood, and their establishments as a rule are not equal to those maintained by the foreign merchants.

The merchants of South America may be grouped in five classes: 1. The general importers who correspond to the wholesale jobbers in this country. 2. Large retailers who import for their own account. 3. Large land owners or development companies who import. 4. The small shops and retailers in the cities. 5. The general stores, usually found in the rural districts and mining camps and corresponding to the general stores in this country.

As a rule, the South American prefers a small turnover and a large profit. He conducts his business in what to us seems a very leisurely manner. The shops in the cities usually open at 8.30 or 9 o'clock, remain open until noon, and then close until three. The most popular shopping hours are from three to six, at which hour most of the city stores close.

The business men, as a rule, are conservative and shrewd, careful buyers. They are well educated, polite and hospitable, with a high regard for music, literature and the fine arts. The South American likes to become thoroughly acquainted with you before he talks business, and in the smaller cities it is advisable to visit your prospect two or three times before your business is even mentioned. Appointments are quite frequently neglected and you will find it desirable to give your prospect plenty of time to make up his mind, because, while he is at all times courteous and hospitable, he greatly resents being hurried or persuaded against his will.

Packing Instructions Must Be Followed

When you receive an order from South America in which definite instructions are given regarding packing, marking and shipping, follow them explicitly. Do not permit your shipping clerk to ignore these instructions on the assumption that what is good enough for us is good enough for any country in the world. It simply will not do! Much of the dissatisfaction with our merchants and products in the past has been caused by failure to follow packing and shipping instructions.

A great amount of the inland freight in South America is moved by animal transport; mules, oxen, llamas and burros are employed, and much of the travel is over rough mountain trails. The average load for these animals is: 100 lbs. for llamas, 150 lbs. for burros, and 200 lbs. for mules. When your customer specifies that his goods are to be packed in cases made of one-inch lumber and measuring not over 2x3 ft., there is a good reason for his not doing so.

On the West Coast of South America good ports are few and most ships are unloaded in the open roadsteads. The merchandise is discharged on lighters, which are flat-bottomed barges with vertical sides and a covering for rainy weather. Packages are lowered on to the lighters by the steamer crane, usually very carelessly. If the lighter is wallowing in a heavy ground swell, the load often strikes with a terrific impact. The necessity for secure packing in strong cases is therefore apparent.

Climatic Conditions Should Be Considered

The moisture, heavy rains and excessive heat should also be considered in preparing shipments, especially if the packages contain perishable articles. The best protection against moisture is a zinc or tin-lined case. Machinery and metal parts should be coated with oil to prevent rust. Pilfering is common in South America, and every effort should be made to make up the packages in such a way as to guard against this. When the packages are transported over numerous routes it is impossible to fix the responsibility for the theft, and there is slight possibility of recovery.

In making up shipments, the tariff classifications of the different countries should be considered. Do not pack in one case different classes of merchandise on which duty is assessed at different rates, as the duty is then assessed on the entire shipment at the highest rate.

Marks on cases should be simple, plain and legible; stencil marking is the best. Some South American countries prohibit receipt of shipments unless marked with stencils. The net, gross and tare weights should be plainly marked on each case, and when the shipment contains two or more cases they should be numbered consecutively.

Terms and Credit

Previous to the war South American merchants were granted liberal credit terms on all their purchases from European countries, and this was an important factor in the control of South American markets by European exporters. During the war American manufacturers have been demanding and getting cash in New York, but these terms must be liberalized if we are to get the maximum business from this country in the future.

The customary terms before the war were from three to twelve months' time. In fact, the German method was to ascertain what terms a merchant had been getting, and then offer him better ones. Credit liberality can easily be overdone, but there is no question but that the volume of our business with South America will depend somewhat on the terms we are prepared to offer.

The South American merchant requires credit for a number of good reasons. The resources of the country are, and will for some time remain, largely agricultural, and although the crops vary in the different countries, the merchants are called on to finance the native farmers; the same as our general merchants in the smaller towns. Bills are not paid until the crops are sold, and the merchant requires credit until he receives his money. Duty must be paid on practically all merchandise imported, and duty and ocean freight amounts to 25 to 75 per cent of the value of the goods. Stocks move slowly, and the merchants are required to carry large stocks on hand to take care of demand between shipments. Financing of some kind is essential, and as interest rates are high in South America the merchant usually prefers to buy where he can obtain credit terms at reasonable rates of interest rather than borrow money locally.

Your advertising copy should be conservative and descriptive of the merits and uses of your merchandise. Superlatives and bombastic or exaggerated statements should be avoided. The North American has a reputation as a "bluffer" in the Southern republics, and the class of advertising copy used by some of our merchants in South American publications has not done much to counteract this reputation.

The FORVM

Simplicity and Frankness in Industrial Relations

By Homer S. Trecartin

THE article by Harry Tipper in AUTOMOTIVE INDUSTRIES of April 10 is entirely too good to let pass without comment. It contains the germ of the truth which will have to be recognized and applied before a settlement of the whole controversy between employer and employee, between management and labor, will be arrived at. Mr. Tipper analyzes the question in a masterly way, but the subject should not be allowed to die or to remain dormant for a moment.

AUTOMOTIVE INDUSTRIES could do a great work by furthering in its pages a broad discussion of the subject which it has so ably taken up, that of industrial relationships. Mr. Tipper very clearly notes the tendency to a lack of simplicity in many of the plans which have been formulated by existing industrial organizations to bring about co-ordination of efforts and interest between workers and the management and employers and other concerns.

Nearly two years ago I assumed control of a manufacturing plant as the general manager. Certain profound beliefs and principles were firmly embedded in my mind as to the proper relationship between the employees in an organization and the management and owners of that organization. They were based largely upon the ideas that I had formed regarding the relationship that should exist between individuals in the very broadest form of association—that of the people and their government.

No Secrecy in Management

I applied these convictions and beliefs in my management of the company, and with very little compromise I was able to adhere consistently to them. What little compromise with the ideals was made was necessary, not from any inherent fault in the ideals, but because the ideals differed radically in some respects from prevailing custom. President Wilson had forcibly declared against secret treaties or secret diplomacy. I issued a plain decree in my small organization that there was to be no secrecy in it as far as the management end was concerned. It took eight or nine months to sell the individuals in the company this idea; the belief that secret conspiracies were an inevitable part of the management side of business were so deeply ingrained that it was necessary to talk it out of practically each man in the company individually.

Their belief in the efficacy of decisions kept confidential among the management was part of their training. As soon as a man was made a foreman he felt that he would no longer be able to take his fellow workers into his confidence about the details of his work. He felt that he was appointed partly because of his sympathy with the management and that there was implied the thought of confidential dealings with them. The superintendents had this idea; they felt that it was part of their job to conspire against the worker, that in business they were on different sides of the fight.

Not once but a dozen times did I call the whole organization together to enable me to tell them my beliefs and my principles that would actuate me in my management of the company, and in every talk, in almost every article I wrote for the magazine which we brought into being, in almost every notice which I had placed on the bulletin board, I had to dwell by direct statement or by suggestion upon this one big guiding principle—that there was to be no secrecy in the organization.

Complete transcripts of the proceedings of every foremen's meeting and of every conference of department heads, both of which occurred regularly once a week, were always typewritten and placed on the bulletin boards so that all could have a knowledge of everything that transpired in these meetings.

A stranger came to me once with the appearance and manners of a successful lawyer and laid on my desk a complete report of one of the meetings of the union, which was very strong in our company and which I never in any way opposed. It was a typewritten record of everything that had occurred at this meeting, in which some radical pleas were made for an immediate strike by two or three of the men in the shop. They were radically opposed to the management and were evidently trying to incite the rest to combative measures.

This man told me that the organization which he represented was nation-wide in its activities and he described to me their method of working. He said that they hired competent workers, paying them a salary of 50 per cent of their regular wages, and that they would then send them to industrial plants where the organization's services were contracted for to get employment. These men would ingratiate themselves with the workers in the plant and would proceed to spy upon them and furnish reports to their superior officers. In addition to their "observation" work other employees would do propaganda work for the management in ways that seemed most advisable, either by appealing to the better instincts of the workers, their sense of patriotism or loyalty, or by creating strife and jealousies among them.

I thanked the gentlemanly individual for his trouble in coming to see me, insisting that he take his report out with himself and his hat, and bade him adieu. I told the men of the occurrence and explained to them that I had not considered for a moment obtaining the services of the agency that had given me the report. I told them that I did not feel that it was any of my business what they wished to do or say in their meetings, that if they felt they had a grievance I would much rather they discuss it in any way they chose and take what steps they thought were necessary to correct the grievance. I told them, however, that I thought they could accomplish a good deal more for themselves by taking me into their confidence, but made them clearly understand that I felt I had no right in interfering with their methods of discussion.

The Simplest Idea Must Be Sold

As Mr. Tipper points out in his article, it is not sufficient to formulate an ideal proposition and then to advance it to the people who will benefit by it.

The very best selling point that a proposition coming from the management to the workers can have is that of simplicity. Mr. Tipper speaks truly when he says that the company lawyers are prone to use the characteristic methods of legal departments and the language of the lawyer. He also says truly that the lawyer's method of approach to the question does not lead to that simplicity and clarity which is absolutely necessary in a case of this kind, if the value of the method is not to be befogged by the verbiage that surrounds its constitution.

I found the application of the simple laws of government that were brought forth by the necessity of the time wholly successful from every point of view. It satisfied the owners, the management and the workers of the little organization of three hundred souls where it was applied, and I believe that without this factor of simplicity little results will be achieved in bigger organizations and it will no doubt be demonstrated that those lacking simplicity will have no results that will benefit or appeal to the masses.

The editor of AUTOMOTIVE INDUSTRIES can do no better work than by furthering in the pages of his publication the creed of, first, correct principles to actuate the owners, managers and workers, and, second, simple methods of expounding these principles and beliefs and simple methods of putting them into practice.

Business Needs Leadership and Government Co-operation

(*Continued from page* 992)

was the first national legal step. Massachusetts has recently enacted a law permitting employees in corporate industries to elect directors of the corporations to provide them with a part in the management. There are cases where through co-operation manufacturers have voluntarily reduced prices. More frequently there is the spirit of co-operation developing by which concerns actually competitive are combining to deal with common problems of their industry."

There is something radically wrong with this country, stated Governor Edge of New Jersey, who claimed that we are lacking business leadership and governmental initiative.

"Our government," he stated, "is stopping, looking and listening, watching and waiting when it ought to be leading. The government should set the example by digging canals, building roads, increasing railway facilities, developing water power and otherwise demonstrating that Uncle Sam is not afraid to buy and hire at prevailing prices. Private business is bound to follow. Capital will be released. Labor will be employed. And our so-called post-war reconstruction prices will evaporate. We must remove the paralyzing hand of over-regulation, governmental prejudice and political management of business."

Governmental regulation that oversteps the requirements of healthy competition has degenerated to governmental persecution. The government has no justification for attempting to run the business of others until it can run its own business successfully.

The government must curtail the present war taxes on industry, said A. L. Shapleigh, decrying the effect of these taxes which take cash from industry, whereas the profits are usually represented only by increased inventory and accounts receivable.

"If the government," he said, "continues to demand so large a share of profits, the ability to increase working capital by addition of earnings to surplus, thus enabling expansion and greater employment of labor, is minimized."

Private Ownership of Merchant Marine Approved

Unanimous approval greeted the demand of Edward B. Burling for the sale of the merchant marine to private American owners. The American marine should include at least all of the ships now controlled by our government of more than 6000 tons dead weight. They should be sold to private companies or individuals and their cost prices should be regarded as war costs just as were the costs of the airplanes, motor trucks, and so forth, and the costs should be written off sufficiently to allow the sale of the ships to Americans on a basis which will allow them to compete abroad.

In a concrete plan for the sale of the marine, Mr. Burling outlined the following:

1—The government should sell all of the merchant marine ships.

2—Purchasers of ships should be free from government direction or regulation of routes or rates except as are now embodied in the law.

3—Re-sale to any foreign countries should be restricted for a period of years.

4—The ships should be sold as a whole fleet, but terms of sale must be liberal, and all of the steel ships over 6000 tons should be sold to Americans only. In order to insure the widest distribution and stimulate financial interest throughout the country the government should invite the formation of shipping associations to represent the different maritime sections of the country, such associations comprising only American citizens or concerns of good financial standing and representing New England, New York City, Philadelphia, Baltimore, the South Atlantic ports, New Orleans, Pacific Coast, and San Francisco, and at the Puget Sound and the Great Lakes.

The budget committee of the chamber recommended the establishment of a national budget to be compiled by the Secretary of the Treasury for presentation to the President, to include the expenditures of the year, the condition of the national treasury, and the recommendations for appropriations for the following year, together with suggestions for raising the revenue needed. The committee also recommended that Congress should establish but two committees to have jurisdiction over all revenue and expenditure proposals, one for the House and one for the Senate.

A demand was made for cessation of price fixing by the Government by A. W. Douglas, who recommended a return to free operation of the law of supply and demand, stating that in his opinion this would bring about a decline in prices. Prolonged applause greeted his statement: "We have had enough of Government control of transportation with its incompetence and extravagance."

There is a lack of systematic business organization of retail distribution and a need for analysis of retail business and especially the introduction of systems of cost keeping, stated by Dr. W. F. Gephart of the Washington University School of Commerce. Another weakness is the failure of distributers to organize their business and classify their patrons.

The Government, he said, frowns upon associations and co-operation among business men and only because of the small minority of inefficient or dishonest men in the groups.

The middleman is the specialized distributer of commodities, he declared, between the producer and the consumer and, while there may be too many of them and too many inefficient ones, yet his function is a product of normal and natural industrial development and there is no need to fear that the individual proprietor in business will disappear.

The present tendency of manufacturers and retailers to continue the large per cent of profit of the past few years was decried by Harry A. Wheeler, president of the Chamber of Commerce, who stated that we must be content to share those profits with the Government if we do maintain them or to so shade our prices as to fall back to the profit level of pre-war years, on the principle of a fair return upon capital actually invested.

"Insofar as public ownership and operation by federal authority is concerned," stated Mr. Wheeler, "the country is farther away from the adoption of that principle to-day than it was a decade ago. But there is a strong tendency to increase public regulation, and it is important that this be recognized because co-operation with public authority will produce intelligent, constructive regulation, while disregard of the tendency will bring increasingly drastic control.

That we cannot look to the Allies for export trade for the next 4 or 5 years, and that we must make large investments in public and private enterprises in those countries, were points emphasized by Maurice Casenave of the French Industrial Mission, Joy Joyce Broderick of the British Embassy and Lieutenant Constanti of the Italian Mission. France,

SO far as public ownership and operation by Federal authority is concerned, the country is farther away from the adoption of that principle to-day than it was a decade ago. —HARRY A. WHEELER, *President United States Chamber of Commerce.*

stated Casenave, is suffering severely from the results of the war, which for four years cost her 25 per cent of her normal tax revenue, the use of 80 per cent of her blast furnaces, 67 per cent of her coal, 90 per cent of her pig iron and 90 per cent of her textiles, because all of these were in the region invaded by the Germans. France, he stated, must first establish her domestic business and her own export business and inculcate a strong policy of thrift in her people before she can consider the import of commodities from foreign countries. The French Government owes the United States almost four billion dollars, and it cannot afford to increase that indebtedness by permitting exports from this country in unrestricted quantities. Similar declarations were made by Broderick and Lieutenant Constanti with regard to Italy and England.

"It is impossible," said Broderick, "to say how long the British restrictions will last, but my latest information is that they will be revised on the first of September. I presume it is quite clearly understood that the restrictions do not seek in any way to discriminate against the United States but apply equally to the manufacturers of all foreign countries."

There must be taxes and bond issues to meet the financial requirements of this country, stated Paul M. Warburg, pointing out that countries starting on the "all-tax theory" have been taught by experience that it was impossible for them to raise the funds required without recourse to huge loan operations, and conversely the "all-loan champions" found that it was foolhardy to try to raise great sums without increased taxation. We must look to those possessed of smaller incomes and subject to only moderate taxation to produce the funds for bond investments, he stated, if owing to drastic taxation the larger incomes cannot now be relied upon to furnish the bulk of the investment funds. The fundamental remedy for the national economic ills, he emphasized, lies in thrift, which spells increased production and decreased consumption and resultant saving. This will bring about a healthy deflation and prices will then find their proper levels and our problems of equitable and reasonable taxation will solve themselves.

A plea for a centralized department to co-ordinate the work of the fifteen different government bureaus actively engaged in export matters was made by Stanley J. Quinn, secretary of the American Association of Exporters, who pointed out that there are bureaus in the departments of Commerce, State, Agriculture, Interior, and Treasury, the Federal Trade Commission, the War Trade Board and the Tariff Commission all interested in matters of concern to exporters, and which have no single place where they can co-ordinate the results of their efforts. England, he pointed out, with her vast experience in export trade, found it necessary to create a separate Department of Overseas Trade to co-ordinate the functions of the various government bureaus, and he pleaded we should do likewise.

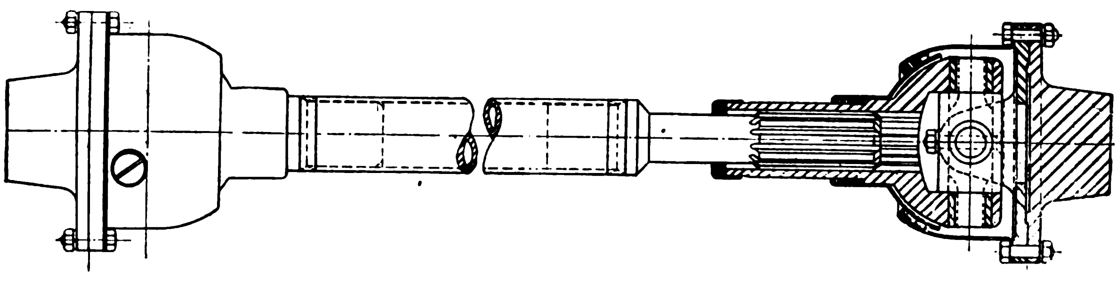
IF our foreign trade position is to be maintained and an outlet found for excess production we must be prepared to sell on credit, or in other words, invest the money due us in foreign securities or in foreign enterprise.—* R. F. LORRE, *Vice-President, Guaranty Trust Co., New York.

New M. & E. Universal Joints

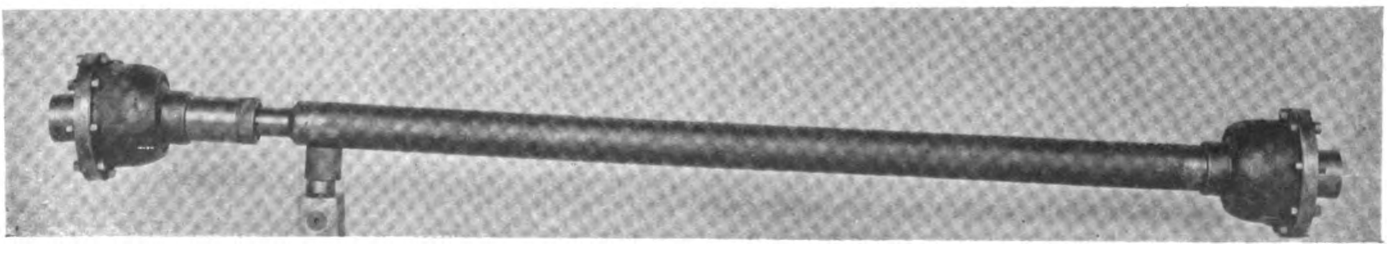
THE Merchant & Evans Co., Philadelphia, Pa., has brought out a new line of universal joints in four sizes, rated at 25, 30, 40 and 60 hp. respectively, at 1000 r.p.m. The joint is of the yoke and block type, comprising one yoke and one disc with two lugs, which are connected by the block. The working parts consist of two hardened pins, accurately ground, the ends of which are inserted in four hardened and ground bushings, which are driven into the yoke and the lugs on the disc, both of which parts are steel drop forgings. The block is inserted between the yokes for the purpose of centering and supporting the pins.

The most interesting feature of the joint is the housing. This consists of two steel pressings with spherical surfaces. The outer part of the housing is secured to the disc of the universal by the same bolts which hold this disc to the machine part to which the universal is connected. The inner part of the housing is provided with a sleeve or hub, surrounding a coiled spring on the hub of the yoke member of the universal and having its outer edge flanged inward. This part of the housing is pressed against the outer part by means of the coiled spring. Between the inner and outer portions of the housing there is a gasket insuring a dust- and grease-proof joint.

The Merchant & Evans Co. makes up complete universal sets, comprising two propeller shafts, two universal joints and a slip joint.



Section of M. & E. universal showing yoke and block construction



The M. & E. universals are made in four sizes from 30 to 60 hp. capacity

Designing for Manufacture

ARE we going too far in the matter of designing for production?

This is something to guard against, as we cannot afford, for the sake of saving in manufacturing costs, to have performance ability decrease. Yet if it is possible to get equal performance and to really design for manufacture so as materially to reduce the number of operations per car, or to reduce the number of tools required and the number of jigs, by making parts do the work which formerly required two or three different kinds of parts, then we have really accomplished something.

Some of the cars not yet in production, but which will probably be shown at the next national show, have been designed very largely from a manufacturing standpoint. The result is that sizes of parts and sizes of tapped holes will be far out of line from a requirement standpoint, as far as stresses, etc., are concerned; yet these sizes are employed simply because they largely cut down the number of tools and the amount of equipment required in the factory. Probably they also cut down the number of operations required, and therefore effect a gain from a manufacturing standpoint. It will be interesting to note the performance of such cars and see if it has been notably sacrificed.

A certain car which will make its appearance about the time of the next national shows is said to have no lefts and rights. Every part which will fit on the left-hand side will also fit on the right-hand side, even to the runningboards. The number of reamer sizes in the tool equipment for manufacturing this car is said to have been cut down by 50 per cent, and the number of other tools has been reduced correspondingly. This means a reduction in labor cost per car, and the money thus saved can be put into materials or it can be taken off the selling price.

Big savings in the cost of labor or in the finished product will result in a lower price and better product to the consumer. With fewer operations, the operations can be more carefully checked, and probably better workmanship will result. This is an important phase in manufacturing and should be closely watched.
